FOREIGN INDUSTRIES.

(From our own Correspondents.)

PARIS, 20TH MARCH, 1888.

THE IRON MARKET.—Since my last report affairs have taken a turn for the better in the iron trade, and on all sides there is talk of rising prices. Already some advances have been announced. Founders' prices are 1s. 6d. a ton higher. In the Haute-Marne efforts are being made to advance the prices of heavy castings by 8s. a ton. Such a rise would be fully justified, for founders have been working at a loss for some time past, and the raw material costs from 1s. 6d. to 2s. a ton more than it did a month ago. From the Loire et Centre we learn that bars and joists are this week quoted 1s. 7d. a ton higher. That a general advance in finished iron will take place cannot be doubted, for in this case too the prices of the raw materials, pig iron and coke, are constantly increasing. Excepting wire, wire rods, and wire nails, which are less sought after, business is more active for all classes of goods. The weather has again become very cold, a circumstance that will delay the expansion of trade in building iron. But it is now clear that the situation is strong, and that we are approaching a busy season. In the midst of all these indications of revival the Paris merchants persist in their headstrong course of "bearing" the market. With every influence against them, however, the issue of this deplorable conflict between manufacturers and the middlemen is not doubtful. The latest information is to the effect that the Longwy pig iron syndicate has announced a rise of 1s. 7d. a ton for forge pig, the quotation now being 41s. 6d. It is further reported that no iron can now be bought for delivery at an earlier date than June.

THE METAL MARKET.—The official quotations for copper show an advance of £2 a ton in the course of the week just past; but the movement is merely a speculative one, and of genuine business there is but little. Consumers are buying up old metal, which is to be had at very low rates, the syndicate not being able to get possession of this stock. Tin continues to arrive in larger quantities, and stocks accumulate. It is surprising that under such circumstances the markets remain firm. The market for lead is very animated, consumers being apparently afraid of a "corner" like what has been so successfully accomplished in the case of copper. Spelter is neglected, and slightly weaker in price.

THE EXHIBITION OF 1889.—M. Berger has issued a notice to the effect that the applications for space in Groups II., III., IV., V., and VI. have been sufficiently numerous to render it unnecessary to further extend the time. The success of the French Section is, he said, now assured. The space allotted in the main building to French exhibitors in Groups III., IV., and V., up to the 1st March, amounted to 64,850 square metres, while the covered space reserved for these groups in the galleries to be built in the Champ-de-Mars is 61,950 square metres. The following classification into groups has been adopted for the official catalogues. One separate catalogue will be published for each group: Group I.—Works of art. Group II.—Education, and apparatus and materials used in connection with the arts. Group III.—Furniture and accessories. Group IV.—Textiles, clothing and accessories. Group V.—Mining, and industries connected with the production of raw materials. Group VI.—Engineering, manufactures, and applied electricity. Group VII.—Food products. Groups VIII. and IX.—Agriculture, viticulture, pisciculture, and horticulture.

THE RIGHT OF WAY FOR UNDERGROUND CABLES.—An interesting question has been raised at St. Etienne, which is of importance in connection with the establishment of central stations for electric lighting. The municipality of the town having given a concession to a company to lay cables in the streets, the local gas company brought an action in the prefectural court to prevent this arrangement being carried out, on the plea that it was an infringement of their monopoly for laying down conduits. The Court has decided that the monopoly granted was only for gas lighting, and that the town could not bind itself to grant sole rights to use the streets for purposes which at the time were unheard of. The attempt, therefore, of the gas company to suppress the electric lighting in this town has consequently failed.

BERLIN, 19TH MARCH, 1888.

THE COAL MARKET.—The condition of the coal market at the present moment is very satisfactory. Stocks in the hands of dealers have been completely sold out, and at the collieries the output, especially of better qualities, is disposed of at once. Large coal is in very good request, especially as the price has been lowered. A good business is being done in coke.

THE IRON MARKET.—In spite of the unfavourable season of the year, the iron market is very active. In Silesia the whole production of puddled iron for the present year has been disposed of, as well as part of next year's output. The rolled iron syndicate has raised prices for the second quarter of the year 2s. 6d. per ton, owing to the improved tone of the market. Foundries and engineering works are well supplied with orders at remunerative prices. The wire nail trade is very active, and the syndicate has succeeded in raising the prices to a remunerative level, and this rise also affects favourably other wire products. The sales bureau of the wire nail syndicate is already in working order, and a uniform method of packing wire nails in packets containing 1000 nails finds much favour with dealers. Other syndicates are in course of arrangement. A committee has been formed to settle the details of a syndicate of chain makers. Spring makers are taking similar steps, and a syndicate of drawn wire makers is also being negotiated.

SEWING MACHINES.—German sewing machine makers are now getting up a petition to Government praying for an increase in import duty on this class of goods. It is somewhat surprising that the makers should wish for an increase of duty, seeing that German made sewing machines are largely exported; but it appears that the movement is directed more especially against the Singer Company, who have of late years cut the ground from under the German manufacturers' feet by allowing purchasers to pay for their machines by monthly instalments extending over a long period. Should the import duty on sewing machines be increased, it is probable that the Singer Company will not be beaten out of the field, but will meet the changed condition of the market by establishing a manufactory in Germany.

CHEMICALS.—The united chemical works in Leopoldshall have decided to manufacture potash on a large scale. Until some time ago the methods in use for making chloride of potassium into potash were not very successful; but Messrs. Borsche & Brünjes have introduced a new process, according to which chloride of potassium can by a wet method easily be made into potash by the use of carbolic acid and ammonia. This process has now been tried for a year, and the results obtained are said to be very satisfactory. The by-products of chloride of magnesium produced in the manufacture of chloride of potassium have, until recently, not been utilised, but were allowed to pollute the rivers into which they were conducted. A new process has, however, now been introduced, under which these by-products will be manufactured into hydrochloric acid.

ELECTRIC LIGHTING.—The larger hotels in Berlin are beginning to introduce electric lighting to a greater extent than has hitherto been the case. The new hotel "Thiergarten," which was erected last year, has now been fitted throughout with glow lamps, the current being supplied from the central station in the Mauerstrasse. This is the first hotel in this town which relies solely upon electricity, no gas or other illuminant being used as reserve. This circumstance is significant, as showing how great is the confidence of the public in electric lighting. In the new restaurant Gambrinus, gas has also been completely discarded in favour of electricity. The electric light installation in the Continental Hotel, which comprises 1000 glow lamps, has recently been completed. The work was carried out by the Allgemeine Elektricitäts Gesellschaft on their own account, the customer only paying for the current used, but not for the cost of putting up the installation.

VIENNA, 19TH MARCH, 1888.

THE COAL MARKET.—Business in all qualities of coal remains very active, and, with the re-opening of navigation on the Elbe, exports by water are again taking place. The total quantity of coal sent out from the Vienna Northern Railway Station during February amounted to 95,000 tons, leaving about 49,000 tons in stock. This traffic benefits almost exclusively the coal mines in the northern portions of the empire, whilst in the south, and especially in Styria, the condition of coal mining is exceedingly unsatisfactory. These mines are not able to compete with those in the north, and many miners are emigrating to America for lack of work.

THE IRON MARKET.—At the present moment it is difficult to estimate the tendency of the iron market, because traffic has been interrupted in many places, with the result of disorganising business. In Galicia, for instance, railway traffic has been completely paralysed, and not a single train could leave Lemberg during several days in the beginning of this month. In Bohemia there were also serious blocks from snow, whilst in the southern provinces the roads are almost impassable on account of the thaw. The markets have not yet recovered from the dull tone which was produced by the death of the German Emperor, and business at the present moment is by no means brisk. The Chamber of Commerce of Lower Austria has resolved to approach the Minister of Commerce with a request that more consideration should be given to the home industry when tenders are invited for the supply of material for the State railways and other Government works. At the general assembly at which this question was discussed, it was pointed out that Austrian producers of railway material are placed in Hungarian markets on the same footing as if they were foreigners, and are therefore at a disadvantage as compared with England and other nations who can produce more cheaply. They are thus beginning to lose the Hungarian market, and to make up for this now wish to secure a greater share of the home market as far as work for the Government is concerned. The Chamber of Commerce proposes that the Government should nominate a Commission, consisting of producers and consumers, which Commission would draw up a list of all those articles which can be produced in Austria equally as good as in foreign countries, and the Government should then undertake to obtain these articles exclusively from Austrian makers. The situation in Hungary is satisfactory. The rolled iron syndicate have raised the base price by 8s., and a slight increase has also taken place in the price of rolled iron tubes. In ship plates there has been a good demand from Roumania, Servia, and Bulgaria, with a consequent hardening in the rates. Pig iron is slightly weaker.

TEXTILES.—The usual spring revival in the textile trades is now beginning to show itself. Cotton prints and zephyrs are in good request, also the better qualities of cretonnes and shirtings. Unbleached cotton goods are still neglected. Linen goods from Reichenberg and Brünn have during the past week been extensively dealt in, and woollen goods are also active. In silks, the market is fairly animated, and in this connection it is interesting to note that the production of cocoons is constantly increasing. Some years ago it was only the south of Tyrol which produced cocoons, but at present considerable quantities are produced in other districts. The harvest last year was 1422 tons of cocoons in the south of Tyrol, 1194 tons in Gradisca, 139 tons in Istria and Dalmatia, and 72 tons in Hungary. The various agricultural associations are assisting this industry to a considerable extent, and this year's harvest will probably exceed the figures given above.

AUSTRIAN TRADE ABROAD.—The Austrian Export Association are making strenuous efforts to open up new markets abroad. The latest development of this Association is a depôt in Greece, erected with the specific object of competing against German importations of machine tools and hardware. The Association are also exporting to Greece considerable quantities of glass and toilet articles. Some time ago an Austro-Hungarian Chamber of Commerce was established in Paris, with a view to facilitate export business to France, and the results have been so far encouraging that a similar chamber for London is now in contemplation.

BRUSSELS, 20TH MARCH, 1888.

THE COAL MARKET.—Both industrial and household coals are very firm, and the contracts for 334,000 tons of coal which are to be made by the State railways on 3rd April, will have a favourable effect on the situation. The Prussian State railways have reduced the tariff for coal from the Ruhr and Wurm districts towards stations on the Belgian Grand Central, and this will enable the German collieries to regain the ground they have lost in Belgium. Although there is still a scarcity of waggons in the Mons district, business is active, and the continued cold causes a brisk demand for household coal. The weather has also caused stocks of nuts and household coal in the Liège district to be greatly reduced. Industrial coal has risen in price, and stocks are low. One of the large collieries in the Charleroi district has contracted to supply small steam coal for the Baltic.

THE METAL MARKET.—Plate makers have decided upon a rise of 4s. per ton, and a similar increase will probably take place in girders and building iron, owing to the strong demand in this line. Foundry pig continues very firm, and so far the imports of English pig have had no influence on the prices of Luxemburg pig. English pig cannot be sold under the rates ruling for our own; but even without a reduction this source of supply has eased the situation for consumers. Contracts will be made to-morrow for three hundred iron coal waggons, one hundred and thirty-five coke waggons, and sixty-five closed goods waggons. The Providence and Monceau works and Cockerill are turning out remarkably good frame plates. Thy-le-Château is busy with light steel rails and girders for America. The Seraing works will perhaps be forced to close for a time, owing to the rise of the river Meuse. Cockerill's will undertake work for the metallurgical company Dniesprovienne, in which the directors of the former company have taken a considerable interest. Railway waggon works are very busy, especially those of the Centre, and orders are being received from Switzerland and a few from Italy. Pig iron makers who have received for trial specimens of ore from the Haute-Moselle, are so satisfied with the results that they have bought largely, and 25,000 tons of this ore will shortly arrive in the Charleroi district. The makers have also the option of buying 100,000 tons in addition to the above. The ore produces 35 to 40 per cent. of iron, and some kinds can be smelted without the addition of flux, whilst the price delivered by water at Charleroi is only 5s. 10d. per ton for the best qualities. The red minette from the Esch district, which is similar, on the other hand costs 7s. 5d. at Charleroi.

FLAX AND YARN MARKETS.—Although, owing to the depreciation of the rouble, very favourable offers have been made at Ghent for Russian flax, there has been but little business. In home grown flax prices are unchanged, although the demand has diminished. Yarns are not much in request, and prices are giving way. Linen is also in a less satisfactory condition.

ELECTRIC LIGHTING OF THE EXHIBITION.— On the 25th inst. the Executive Committee will make final arrangements for giving out the work for the electric lighting of the buildings and gardens of the Exhibition. Offers have been made by many electricians to supply various apparatus free of charge, both for arc and incandescent lighting; but other offers were on the basis of payment per lamp-hour, the average price asked being from 2d. to 3d. for a 10 to 12 ampère arc, and of 3d. to 35d. per 16-candle power glow lamp. For the arc lighting offers have been received from the following: The Thomson-Houston Company, (engineer, M. Admirallie), seventy-five 2000 nominal candle power lamps, with an 80 h.p. steam engine; Messrs. Bouckaert & Co., of Brussels, four lamps of 25 ampères, six of 16 ampères, forty-two of 10 ampères, and sixteen of 6 ampères; M. Dulait, of Charleroi, twenty-five lamps of

Digitized by Google

15 ampères, four of 24 ampères, and six of 4 ampères, all at 35 volts; Messrs. Jaspar, of Liège, twenty lamps of 12 and 6 ampères; the Gülcher Electric Light Company, lamps of 10 ampères, &c. For incandescent lighting the following have made offers: M. Dulait, 200 lamps; M. Khotinsky, 500 lamps; M. Bury, 500 lamps; l'Industrielle, 750 lamps; and Mr. Bernstein, 150 lamps of 30 c.p. to 50 c.p. In the machinery section there will be three rows of 10 ampère arc lamps, seventeen in each row, and one row of 16 ampère lamps will be placed in two rows on either side. The 10 ampère lamps are hung at a height of 30ft., and the 16 ampère lamps at a height of 42ft., the object of the latter being to illuminate the side galleries, which are 20ft. above the floor. There is a 10 ampère arc lamp provided for every 1900 sq. ft. of floor space. M. Pieper, of Liège, has already obtained a concession for lighting the aquarium, the casino, and the German breweries. He will also work the electric tramway.

DÜSSELDORF, 19TH MARCH, 1888.

THE COAL MARKET.—Great activity continues to be a distinguishing feature of the coal trade. The wintry weather has occasioned a renewed demand for house coal, and the revival of industry causes an unusual degree of activity in the market for steam coal and blast furnace coke. Prices have an upward tendency, and seem likely to remain firm for some time to come. The first contracts for the year for locomotive coal were tendered for the other day, when the offers received showed an advance of from 2s. to 3s. per 10-ton truck load on last year's prices. The tenders ranged from 5s. 9d. to 6s. 1d. a ton for locomotive coal, and 6s. 9d. to 7s. 6d. for gas coal. Coke was offered at prices varying from 9s. to 10s., and briquettes at from 7s. to 8s. a ton. The Customs returns for January give the exports of coal in that month as 739,173 (753,958) tons, those of coke as 72,232 (63,235) tons, and those of briquettes as 12,571 (12,817) tons; total, 823,971 (829,447) tons, the quantities within brackets being those for last year. It will be observed that the trade in coke shows an expanding tendency.

THE IRON MARKET.—The general aspect of the iron market has not greatly changed since my last report. Business is on the whole quieter in pig iron, the production of the blast furnaces being all sold forward to the end of June. Still, there is a steady demand, and prices remain very firm. Forge pig is most sought after. The market is fairly active for spiegel, despite the fact that no orders now arrive for the United States. There has been a better inquiry this week for Bessemer pig, and prices are a little harder. The export trade in crude iron is lifeless, while the imports of foreign iron increase—effects wholly due to the high level to which the syndicates have raised prices. It is contended by advocates of that artificial system of regulating trade that this objection does not hold, since many, if not most of those who work for the foreign market, have their own blast furnaces; but the greatly increased prices in the home market have occasioned a corresponding rise in the prices of iron ore and coke, so that manufacturers are unable to produce at the same cost as formerly. The market for finished iron and steel is fairly animated, but there is languor in some branches of the trade. Bars exhibit increasing dulness, and joists are in less demand. The latter circumstance is probably due for the most part to the inclement weather, which delays the resumption of building operations. There is still a brisk demand for plates, and many manufacturers have booked enough orders to keep them employed for several months to come. Business in sheets is somewhat dull, and there is increasing dulness in the wire trade. United States' orders are few and unimportant. There is a steady business in wire nails. During the week a good deal of buying has taken place on Belgian account. Home prices are as follow: Bars, something above the base prices of £6. 2s. 6d. and £6. 5s.; angles, £6. 12s. 6d.; hoops, £6. 17s. 6d. to £7; steel billets, £6. 15s.; wire nails, £8. 5s. per ton.

GERMAN TRADE WITH ITALY.—The German newspaper press is urging manufacturers to take immediate and energetic steps to turn to account the opportunity afforded by the war of tariffs between France and Italy. It is pointed out that English traders will seek to increase their hold both in the French and the Italian markets. Judging from the activity of German agents in Italy at the present time, manufacturers scarcely need the stimulus of these admonitions. The prospect for German trade in this direction is very encouraging.

LILLE, 20TH MARCH, 1888.

TEXTILE MANUFACTURES.—The week has passed without bringing any event which the most sanguine could construe into an indication of improving trade. The linen trade has been slightly more active than it was last week, but no improvement has taken place in prices. The woollen trade remains lifeless, and there are no indications of immediate revival. The return of cold weather has given an impetus to the hosiery branch of the trade; but in all other directions there is almost absolute stagnation. This protracted calm is giving rise to disturbing apprehensions, both among manufacturers and the persons in their employ. The market for raw materials is somewhat firmer. South American combed wool is quoted 4·70 francs to 4·90 francs; Australian, 5·50 francs to 5·75 francs per kilo. Noils, which had receded a little, have recovered to 3 francs and 3·15 francs for South American, and to 3·30 francs and 3·70 francs for Australian. Business in cotton goods is very quiet. A report from Lyons describes the silk trade as depressed by the new retaliatory tariff directed against Italy. The silk goods, velvet, and ribbon industry is largely dependent upon Italy for the raw material, and it will take years to establish a trade in the same commodities with Spain, Portugal, China, and Japan.

FLAX AND YARN MARKET.—The market is fairly animated for home grown flax, but prices show a tendency to weakness. Russian has been less largely dealt in. Tows have been in strong demand for export; but the home market is calm, and prices are in favour of buyers. The situation has not materially changed for yarns. There is some life in the export trade, but the requirements for home consumption are for the moment not great. In some instances spinners have shown a disposition to take lower prices. There is still a good demand for jute yarns. Hemp is in better request, and prices are very firm. Raw cotton has receded in price 1s. 6d. in consequence of forced realisation on the part of some New York speculators for the rise; but this has had no visible effect on the market for cotton yarns. Spinners having booked plenty of orders, are not disposed to make concessions.

THE IRON MARKET.—The iron market is unchanged in its principal features. Though business is less animated than it was a fortnight ago, there is a steady current of orders sufficient to keep the books well filled. Prices remain unaltered at £5. 4s. for bars; but an advance of 4s. is expected as soon as the forge masters of the Nord and the Centre have settled the question of zones, for which purpose there is to be a meeting this week at Paris. The strikes at the Providence works and the Manbenge blast furnaces continue. The founders of the Valenciennes district have agreed on the principal bases of the syndicate, but the details remain to be discussed. Engineering works are busy. M. Walrond is erecting a small steel works at Louvroil for M. G. Dumont.

THE BUILDING TRADE.—It is significant of vigorous industrial life in this locality that in the arrondissement of Lille alone there are upwards of 1600 building contractors, employing in all about 25,000 hands.

MILAN, 19TH MARCH, 1888.

RAILWAYS.—Mr. Baccarini has compiled some interesting statistics with reference to the Italian railways. During the last seven years 1660 miles have been constructed by Government, and 194 miles by private enterprise, making a total of 1854 miles. The cost of construction amounts to about £11,500 per mile, but nearly all the lines are single track. At a recent meeting of the shareholders of the South Adriatic Railway Company, a motion was put and unanimously carried authorising the directors to issue 6000 new shares of £20 each, the capital of £120,000 thus raised to be applied to the extension of the system. The Mediterranean Railway Company have laid before the government inspector for his approval and sanction a project for the construction of part of the circular line which is to surround Milan. It is probable that the proposal will receive the royal assent with but slight modifications. The part to be taken in hand at once is 3¼ miles long. The new line between Cuneo and Mondovi in Piedmont was opened for traffic last month.

SHIPPING SUBSIDY.—For some years past the Peninsular and Oriental Steamship Company have had a contract with the Government for a weekly service between Venice and Brindisi, and for this they received a subsidy of £20,000 per annum. This contract had already been twice renewed and was again about to be renewed when the Peninsular and Oriental Company made representations to the Government that owing to the competition of the North German Lloyd they did not care to continue the service to Venice unless the subsidy were raised to £50,000 per annum for a weekly, or £34,000 for a fortnightly, service. The Italian General Navigation Company took advantage of this hitch in the negotiations by offering to run a weekly service between Venice and Brindisi for £40,000, and a fortnightly service for £20,000 per annum. A commission of nine members was appointed by the Government to investigate the respective offers of the rival companies, and seven have decided in favour of the Italian company, whilst two recommended the contract to be given to the Peninsular and Oriental Company. It is therefore probable that the Government will accept the offer of the Italian General Navigation Company.

MADRID, 19TH MARCH, 1888.

COTTON MILLS.—A few years ago the cotton spinning industry here was in a most flourishing condition, and dividends of 30 per cent. were sometimes paid. As a consequence, numerous new mills were erected, until considerable over-production took place, and the situation is now very bad. An agreement has been come to among the most influential mill owners to raise prices 10 per cent., and if this fails to make business sufficiently remunerative, it is proposed to reduce the production by one-half.

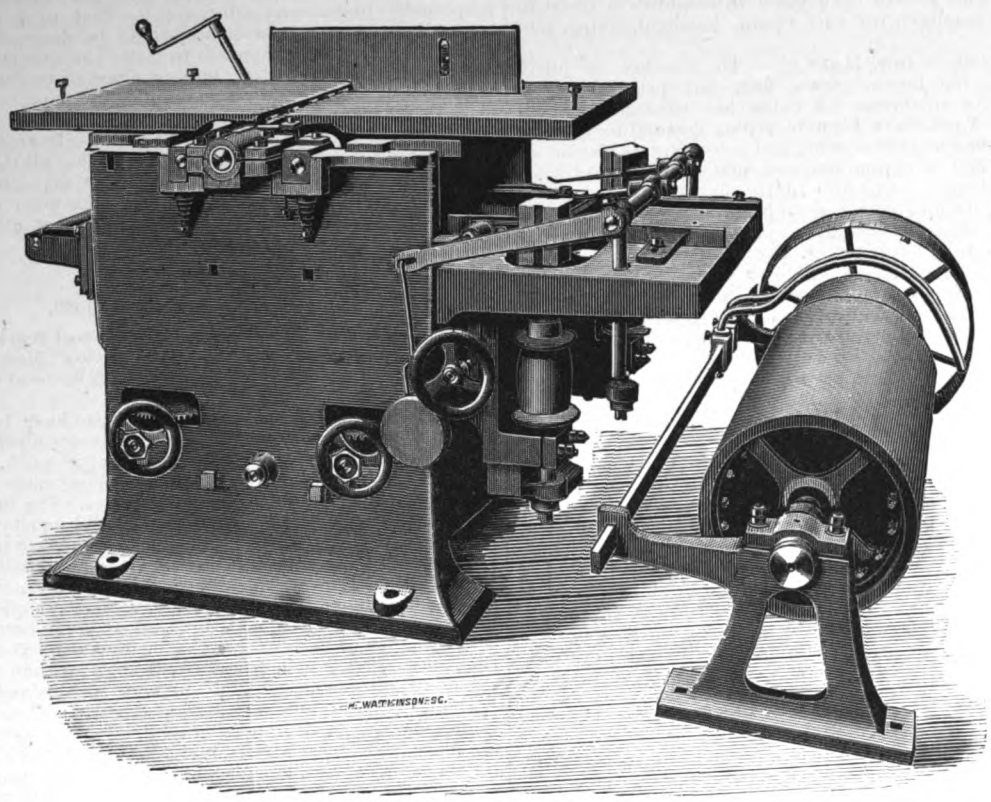
PETROLEUM.—Among the financial proposals laid before the Cortes is one for an increase of the already very high duties on petroleum. The object is to increase the Custom House receipts; but it ought to produce the opposite effect if some enterprising British company, acquainted with the Scotch shale oil industry, were to establish works in the north of Spain. I am of opinion that if shale oil can be produced in Scotland, and hold its own against petroleum imported free of duty, it would be possible to produce it in Asturias at an enormous profit, as the duty on refined petroleum entering Spain is over 140 per cent. One disadvantage, however, lies in the fact that our legislation is perpetually undergoing alteration, so that next year it might happen that the duties would be decreased. It would therefore be inadvisable to make the experiment if the cost of plant is heavy; but some Scotch works which is at present doing bad business might find it profitable to transfer its plant to this country.

CHROME STEEL.—The Trubia Ordnance Works are turning out chrome steel of such reliable quality that all the tools used there are now made from it. This department is under the charge of Captain Cubillo, a member of the Iron and Steel Institute, who has devoted great attention to the manufacture of steel.

NEW YORK, 10TH MARCH, 1888.

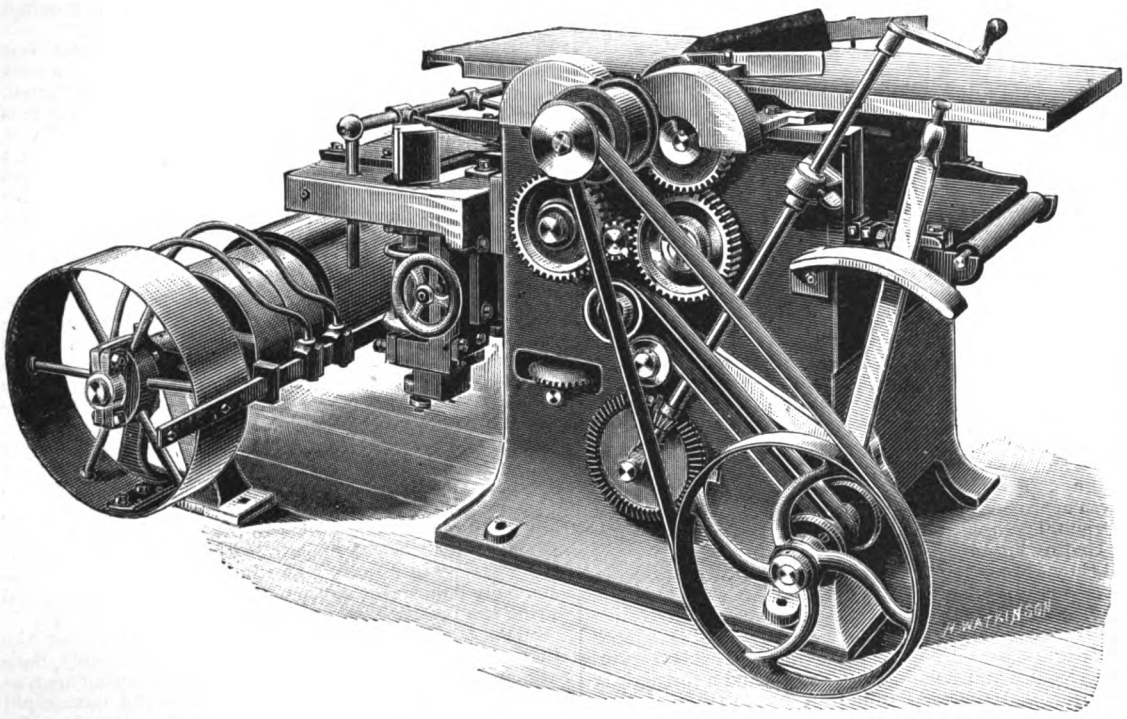
THE COAL MARKET.—The anthracite coal market has got back to its condition before the strike. Most of the Reading collieries are again at work. The total output shows a considerable increase.

THE IRON AND STEEL MARKETS.—There have been no new developments in the pig iron market during the past week. Prices are not lower, but the feeling is weak. There is no scarcity of iron, and attempts are being made to get orders for future delivery at present prices. The furnaces are not working to anything like their full capacity. It is stated that there are large orders waiting for a lower market, but the rumour is very indefinite. In manufactured iron business is falling off, and very few mills are running at much more than half their capacity. Western offers are made for such large quantities, and at such favourable prices, that there is nothing in the business here. Generally the iron market is in a worse condition now than at any time during the winter, and it compares very unfavourably with the state of trade a year ago. Although there is an immense quantity of iron being used, all the orders which are placed are for small lots, and none of the mills have a large amount of business ahead. The steel rail market is quiet. The mills are running moderately full, but the contracts are not very large. The time of year is favourable for an increasing demand, and prices remain firm. One order of 5000 tons for an Eastern railroad is reported at £8. 2s. 6d. per ton.



THE METAL MARKET.—Copper is rather firmer, but with little change in price. During the last week about 2,000,000lb. have been sold at 16 cents per lb. for March, and 16·20 cents to 16·30 cents for April delivery. There is no confirmation of the rumour that the Calumet and Hecla have sold their output to the syndicate. In the tin market purchases amounting to 210 tons have been made at prices varying from 36 cents per lb. for March, to 31·60 cents for May delivery. The market has improved somewhat, and speculative buying to the amount of about 600 tons on the metal exchange has caused an advance of 5·15 cents per lb. for spot, and 5·17 cents for April delivery.

THE TARIFF.—If it were believed that the present Congress would make any serious attempts to change the tariff, the Bill of Mills, the chairman of the Ways and Means Committee, would be sufficient to excite manufacturers in almost every branch of trade. The proposed new tariff is mainly free list. Some of the changes in the Bill are indicated below: Iron in pigs, spiegel iron, reduced from $6·72 to $6 per ton; iron and steel rails (not over 25lb. per yard), from $17-$20 to $14 per ton; flat rails (punched), from $17·92 to $15; rails or bars (over 25lb. per yard) $16·68 to $11 per ton; tin plates, from 1c. per lb. to free; wools, &c. (unmanufactured) range from 2½-36c. per lb. to free. There does not seem to be any possibility of the Bill passing the Lower House in anything like its present shape, and it is extremely doubtful if any general Tariff Bill will be passed during the present session.



SHIPBUILDING.—The boats used for ferries over the Hudson River at New York, by the Pennsylvania Railroad, are all being equipped with steam steering gear, as the crowded condition of the river makes the more rapid handling of the boats a necessity.—A twin screw boat for the United States lighthouse service is nearing completion in Baltimore. The hull is of steel, and of novel construction. The forward part of the steamer is of ordinary shape, but abaft dead flat; the ship being practically a double one. The keel separates into two parts, and each screw shaft goes through its own stern post. The boat is 180ft. over all, 29ft. beam, and is of 11ft. depth of hold. The engines are compound, with 15in. and 28in. cylinders diam., by 27in. stroke.—The contract for a new steel steamship, 300ft. long, 46ft. beam, has been given to Messrs. Cramps by the Clyde Steamship Company for their southern trade. Triple expansion engines, with all the latest improvements, are to be fitted. The steel turned out by the Pacific Rolling Mill Company of San Francisco, and used in the construction of a vessel for the Government, has been found by the inspectors to more than fulfil the requirements. The breaking of beams, which took place early in the year, and caused considerable comment among officials, has been shown to be caused by improper treatment of the beams after leaving the mill. Tests made of four samples from each heat give an average of 61,000lb. tensile strength and 30·5 per cent. elongation in 8in. for angles; hull rivets, 53,308lb. and 31·5 per cent.; boiler rivets, 61,220lb. and 29·3 per cent.; and the cast steel used for stem, stern post, and ram gear, 66,870lb. and 19 per cent. elongation.

IMPROVED WOOD PLANING MACHINE.

FRONT VIEW OF MACHINE.

BACK VIEW OF MACHINE.

IMPROVED WOOD PLANING MACHINE.

THE accompanying illustrations show an improved wood planing machine constructed by Messrs. John Sutcliffe and Son, wood working machine makers, Jail Lane, Halifax. This machine is provided with a top table for planing wood, which may be in twisted condition, to a true plane surface. The body of the machine is cast in one piece, and carries a horizontal steel spindle fitted with three knives and two steel feed rollers. One of the knives may be removed, and a moulded cutter put into its place for moulding and planing the board at the same time. The roller which forces the wood under the knives is fluted, while the other one behind the spindle is smooth, so that no marks are perceptible on the wood after having passed through the machine. The table is also provided with two carrier rollers arranged under the two feed rollers in such a manner that they just protrude above the table. By these means the friction between the wood under operation and the table is obviated. Wood which may be in a twisted condition is first planed on the top table to a true plane, and then passed face downwards on to the lower table, where it is planed to the required thickness. This lower table is also fitted with two vertical spindles, which plane, mould, or tongue and groove the sides of the board, according to the shape of the cutters fixed to the spindles. The depth of the cut is regulated by raising or lowering the tables, which are arranged to take a cut up to $\frac{5}{8}$in. in depth. By means of the fence shown on the top table, rabbets, chamfers, or stop chamfers may be produced. The feed motion of the bottom table is very powerful, being capable of working with a cut $\frac{3}{8}$in. deep without any slipping of the gear wheels driving it. A rule is fitted to the side of the machine, over which a pointer on the table moves, showing the exact thickness to which the wood is being planed. We understand that the machine will plane any thickness from $\frac{1}{16}$in. to $7\frac{1}{2}$in., either hard or soft wood, and that it is made from 12in. to 30in. in width. It will be seen from our illustrations that the machine is very compact, and suitable for its intended purpose.

RING SPINNING MACHINERY.*

AFTER giving a general outline of the machine as made at present, the author gave a brief history of the ring frame, defining it as a machine of which a stationary annular ring is an essential feature, in which case no earlier date than 1828 can be assigned to it. In that year a patent was granted in the United States to one J. Thorp, who invented a ring which was in two pieces, and a groove was thus formed in which a solid hoop was placed. The yarn was conducted between the two rings, and was drawn round the periphery of the hoop by the pull of the spindle. In the next year a patent was taken out in the United States by Messrs. Addison & Stevens, in which the first mention is made of a traveller. The first patent in this country was granted to Messrs. Sharp & Roberts in 1834. The spindle was borne by the bolster and footstep, the warve or whirl being placed between the two. The copping rail carried the ring, which was fastened on to the top of the rail. The traveller was formed from flat wire coiled round a rod, and cut into short lengths for the purpose. The spindle carried a bobbin which rested on a braid or disc on the spindle, and was positively driven by means of a pin in the braid which engaged with a hole or slot in the flange of the bobbin. All the essential features of the modern ring frame are found in this machine, the roller stand being inclined, the bobbin positively driven, and the ring and traveller identical in principle with those now used. The next patent in point of time granted in this country was that of Charles de Bergue, which was granted in 1836, being identical in principle with that of J. Thorp. The invention of John George Bodmer in 1837 was next referred to. Sketches of the traveller used were shown. The lower ring was attached to the rail by bolts, and served as a support for the traveller. An upper ring or cover was employed, and kept in position by a button. The revolution of the spindle pulled round the traveller, as in the preceding patents. It was somewhat remarkable that in the specification of this patent Bodmer appears to have stated some deductions which are very much akin to the speculations of some modern inventors. He states that at first, when the spindle was revolving slowly, the eye in the traveller would be close up to the spindle, while with the increase of speed the centrifugal force created would cause the traveller to fly outwards. It was on the balance of the forces of tangential and centrifugal impulses thus given to the traveller that Bodmer relied for the efficient winding of the yarn on the spool. He laid down as a rule that the weight of the "flyer" depended entirely on the work to be done and the counts to be spun, thus showing that even at this early day there was a very clear apprehension of the principles underlying this process. The next patent of which notice was taken was that of John Platt and Thomas Palmer, which bears the date of 1847, this being the first time in which an attempt was made to spin on the bare spindle cops similar to mule cops. The spindle was of the ordinary type of mule spindle, and it had surrounding it the ring attached to the copping rail, to which the usual vertical movement is given. The specification states that the patentees had discovered that by giving the rail the necessary traverse by means of a cam of the requisite shape, "pin" cops could be very readily spun on this machine. After this date little use was made of the ring frame until in the year 1866 Messrs. J. & P. Coates and Messrs. Clark & Co., both of Paisley, and both having mills in America, introduced into this country short sample ring frames for the purpose of twisting sewing cottons, and in February, 1867, Messrs. J. & P. Coates ordered from Messrs. P. & J. McGregor, of Manchester, eight sample frames of 238 spindles each for twisting purposes. In May of the same year Messrs. Clark ordered from the same firm a sample frame, and during that and immediately succeeding years many repeat orders were executed by Messrs. McGregor. Messrs. Wm. Higgins & Sons, of Salford, also made machines on the American pattern for the same firms and for the United States. In June, 1867, Messrs. McGregor made for Messrs. Knowles, of Burnley, a ring spinning frame, all those previously referred to being for twisting, and in October, 1869, they made for Messrs. John Dugdale & Brothers, of Lowerhouse, near Burnley, fourteen frames of 364 spindles each. The author is not aware of any earlier actual use in this country on a large scale of ring frames either for spinning or doubling. At the latter end of 1872 Mr. James Blakey, a representative of Mr. Brooks, paid a visit to the United States, and there investigated closely the use which was being made of the machine, the result being that Mr. Brooks began to manufacture the machine with energy. In 1870, Mr. J. H. Sawyer, of Lowell, Mass., patented the spindle bearing his name, and which was introduced into this country under the name of the "Booth-Sawyer." The main principle of the spindle was the devising of a means by which the top bearing was carried up inside the bobbin, thus sustaining it at a higher point than had been before possible. Special provision is made for lubrication of the bolster and footsteps, and both are supplied with covers. The Booth-Sawyer spindle is beyond doubt an efficient spindle, and constituted a very great advance on the spindles previously used. The introduction of the Rabbeth spindle into this country by Messrs. Howard & Bullough about the year 1874 led to its wide adoption, and the practical supercession of the Sawyer. The principle of the Rabbeth is that of the Sawyer so far as the position of the upper bearing is concerned, but it has the further merit of being entirely self contained. The latter feature was not new in the annals of British invention, as in a patent granted to David Cheetham in 1857 a self contained spindle was included. In addition to this, in a silk mill at Renfrew, occupied by a Mr. Gavin Pollock, a self contained spindle made with a brass bolster had been working for a great number of years prior to 1857; but this use was not generally known. In 1836 a patent was granted to Mr. William Wright, in which this principle of a self contained spindle is foreshadowed, the driving warve being at the lower end of a hood fitted on to the spindle. The first form of the Rabbeth spindle had the bobbin entirely above the bearing, as the specimen exhibited will show. The first patent taken in America by Mr. Rabbeth was dated the 2nd April, 1867; but on the 18th of December, 1860, Mr. E. M. Steeve patented in the same country a spindle which is almost identical with the Rabbeth spindle.

* Abstract of a paper read by Mr. Joseph Nasmith, before the Manchester Association of Engineers, on 10th March, 1888.

Digitized by Google

Various modifications of the Rabbeth spindle have been made, including the Dobson-Marsh, which provides for a readier means of oiling by taking off a cap at the lower end of the spindle, and thus allowing the dirty oil to run away—this necessitating pumping out in the Rabbeth. In all essential features the Rabbeth may be taken as the best type of self contained spindle, in which the spindle proper is sustained by rigid bearings, and one of its chief merits is that it can be readily adjusted so as to be quite true with the ring. As a matter of fact this was practically the only advance noticeable in the Rabbeth spindle over its predecessors, and was not perceived even by its inventor until after spindles made under his first patent had been working some time. During the past few years, however, a new type has been introduced, to which the designation of the "top" spindle was given, and which was, while held in a long bearing at the top of the bolster, free to move at its foot until it found its position of steadiness. It was found, however, that the changes of position when the balance was disturbed were so abrupt that it was necessary to restrain the movement to a certain extent. Several types of this class of spindle were described, and it was noted that the adoption of spindles with elastic bearings had been followed by a shortening of the driving sleeve and a lowering of the top bearing. In the patent of William Wright, previously referred to, provision for an elastic bearing at the bolster was made, the collar of the bolster being grooved and a leather washer fitted, the outer periphery of the washer fitting a hole formed in the rail. The author subsequently dealt in detail with the machine and considered some of its principles. In conclusion, he pointed out that the success of the machine depended on the accurate construction attained by modern machine tools, and that it was as a twisting rather than as a spinning machine that its use was renewed. In answer to a question, the author said that with preparation machinery not more than sixty-five ring spindles per h.p. could be safely counted upon, and in some cases the number was less.

SHIPBUILDING NOTES.

Messrs. Short Brothers, of Pallion Shipbuilding Yard, Sunderland, launched on the 15th instant the steel screw steamer "Rio Tinto," which has been built to the order of Mr. John Tully, of Sunderland. The vessel, which is built of Siemens-Martin steel, is classed 100 A1 under special survey on Lloyd's Register, and is constructed with a cellular bottom throughout, divided for trimming purposes. There is a full poop aft for the accommodation of the officers, the saloon being handsomely panelled in Lincrusta-Walton, hurricane house amidships, with engineers' rooms in aft end, and topgallant forecastle for the accommodation of the crew; a fore and aft gangway between the deck erections, allowing a ready access in bad weather, &c. As the vessel will be principally engaged in the ore trade, suitable trunks are provided. All the latest appliances are fitted for rapid dispatch in loading and discharging cargo, including four steam wenches on the compound principle, supplied by Messrs. Wigham & Co., South Hylton; and having a multitubular donkey boiler of 150lb. per square inch working pressure. The "Rio Tinto" will be fitted with triple expansion engines of 180 n.h.p., with two steel boilers of large size, working at a pressure of 150lb. per square inch, by Mr. John Dickinson, Palmer's Hill Engine Works, Sunderland.

Messrs. Jos. L. Thompson & Sons, North Sands, Sunderland, launched on the 17th inst., the steel screw steamer "Birchfield," built to the order of Mr. Jos. Brown, of Liverpool. This vessel has a dead weight capacity of 3,500 tons, and is of the well-decked type, with raised quarter deck, hurricane house, and topgallant forecastle, built on the web frame principle, dispensing with hold beams. Six water tight bulkheads divide the vessel into seven compartments. The vessel is to be fitted with triple expansion engines of 220 n.h.p., by Mr. John Dickinson, of Palmer's Hill Works, and with two steel boilers of 150lb. per square inch. Direct steam windlass, steam winches, steam steering gear, and donkey boiler on deck are included in the vessel's equipment.

Messrs. W. R. Potter & Sons launched from their shipbuilding yard, at Queen's Dock, Liverpool, last week, a fine new sailing ship for the Calcutta trade. The "Seafarer" is a sister ship to the "Wayfarer," launched from the same yard about eighteen months ago, and is of the following dimensions: Length, 230ft.; beam, 41ft.; depth of hold, 24ft. 6in.; tonnage, net register, 2200 tons; dead weight capacity, 2500 tons. She is classed 100A at Lloyd's, and the framing and plates are in excess of the requirements of either Lloyd's or the Board of Trade. She is constructed of Siemens-Martin steel, manufactured by the Steel Company of Scotland, the Consett Company, and Messrs. Dorman, Long, & Co. She is fitted with Barfield's patent steam winch.

Messrs. William Simons & Co., of Renfrew, have received another order for one of their patent hopper dredgers, for harbour improvements in the East.

A New Pottery Kiln.—A new pottery kiln, fired by gaseous fuel, is in operation at the Wilderness Terra Cotta Works, Mitcheldean, Forest of Dean. This kiln, which has been constructed by Mr. Carr—from the designs of Mr. Thwaite, C.E., of Liverpool—has several new features. It is recuperative, and the heat radiated from side walls is also recovered. The kiln is so arranged that a perfectly uniform heat in the muffle can be obtained; but full fuel economy is only obtainable when there are two or more kilns. In that way the gaseous fuel produced from a Thwaite gas producer can be continuously consumed—first on one kiln and then on another. We understand that a second kiln is to be constructed, so that this economical advantage may be accomplished.

Notices of Meetings.

THIS WEEK.

Institution of Naval Architects.—Friday, 23rd March, noon and 7 p.m. Continuation of annual meeting. Papers to be read and discussed.

Balloon Society of Great Britain.—Friday, 23rd March, 8 p.m. Lecture on "Great Britain and the Colonies," with Notes of Personal Travel in Australia, by Mr. J. E. Cracknell, F.R.G.S.

NEXT WEEK.

Society of Arts.—Monday, 26th March, 8 p.m. Cantor lecture on "Alloys," by Professor Chandler Roberts-Austen, F.R.S. —Tuesday, 27th March, 8 p.m. Foreign and Colonial Section. Paper to be read on "The Panama Canal," by Mr. J. S. Jeans.

Institution of Civil Engineers.—Tuesday, 27th March, 8 p.m. Further discussion on paper on "Economy Trials of a Non-Condensing Steam Engine—Simple, Compound, and Triple," by Mr. P. W. Willans, M.Inst.C.E. Paper to be read (time permitting), on "Compressed Oil Gas, and its Applications," by Mr Arthur Ayres, M.Inst.C.E.

The Society of Architects.—Tuesday, 27th March, 7 p.m. Special general meeting.

Chemical Society.—Wednesday, 28th March, 8 p.m. Anniversary meeting. President's address. Election of office bearers.

Civil and Mechanical Engineers' Society.—Wednesday, 28th March, 7 p.m. Paper to be read on "The Development of Machinery in Relation to Hand Labour," by Mr. Ambrose A. Myall, Assoc.M.Inst.C.E.

PRICES CURRENT, 22nd March.

Quotations at per ton, unless otherwise specified.

Electric Lighting Contract.—The British Consul at Königsberg announces that the municipal authorities of that town are advertising for tenders for the construction and maintenance of the necessary works for lighting the streets with the electric light. A copy of the conditions, with a plan of the city, can be obtained from the chief cashier of the municipality on payment of two and a half marks, and tenders will be received until the 16th April next.

Delta Metal.—We understand that Mr. Dick has formed his business into a company, in order to enable him to better meet the greatly increased demand for his metal. Sir Edward Reed is the chairman, and Mr. Charles Cammell, of the Cyclops Works, Sheffield, is one of the directors of the company. Although the company was registered only last week, nearly all the capital at present required has been subscribed for by users of the Delta metal.

We regret to record the death of Mr. Robert Hadfield, of Sheffield, on the 21st inst. Mr. Hadfield was the founder and principal partner of the Hadfield Steel Foundry Company, Sheffield. He erected the present extensive works in Newhall Road, and there developed an extensive business in steel castings, and invented processes for the rapid making of steel, which embodied some of the best features of the Bessemer, the Siemens-Martin, and similar processes. His firm have attained considerable celebrity as makers of steel castings for a great variety of purposes.

Balloon Society of Great Britain.—At the weekly meeting of the Society held at St. James' Hall, Piccadilly, Mr. John Parnell read a paper on "Ancient Engraving," tracing the art from its rise in Italy and Germany in the fifteenth century, and through Europe up to the close of the eighteenth century. Among the etchings and engravings exhibited by the lecturer, were many by the great Italian painters and artists of the Dutch, French, and Flemish schools; mezzotint and line engravings by English engravers of the seventeenth and eighteenth centuries; Bertelli's designs for the Carnival of Venice, A.D. 1643; Hogruberg's view of Cambridge, A.D. 1572; Lafreri's print, A.D. 1560, of the Mithias Tablet; and Houbraken's print of William Cecil, Lord Burleigh. The following resolution was moved and carried during the meeting: "That the art of engraving has contributed largely to the culture and æsthetic taste of all civilised people, and has been the means of handing down from generation to generation representatives of customs, habits, facts, and events of vast importance to the human race."

HOME INDUSTRIES.

MANCHESTER, 22ND MARCH, 1888.

THE ENGINEERING TRADES.—Stationary engine builders continue to be fairly well employed, but there is not any great accession of business. A large quantity of repair work is in hand, and a satisfactory trade is being done with foreign parts. Millwrights are only moderately busy, and in some cases are finding orders difficult to obtain. A continuance of the prosperity observable in the spinning trade is almost certain to result in the formation of new companies, and a busy time may consequently be expected by engine builders and millwrights. Boiler makers, without exception, continue to be fully employed, and there appears to be no prospect of any falling off in this department for many months to come. The locomotive trade has improved slightly, and there are indications of a decided advance in this branch of engineering. The railway carriage and waggon builders in the district are as a rule well occupied, and there are fewer complaints than for some time past. Machine tool makers are also finding a few more orders, but are not as yet fully supplied. Cotton machine makers are almost without exception very busy in all departments. Ring spinning machinery especially is freely ordered; but all classes of preparation machinery are in great demand. It is pleasing to note that the older concerns, such as Messrs. Platt Brothers and Co., of Oldham, are obtaining a full share of current business. Loom makers are still very busy, and orders are coming in freely, although it is hardly likely that the extension and building of sheds will take place at the same rate as has been the case during the last two years. The Union Manufacturing Company of Rochdale have ordered their engines for their new shed from Messrs. J. and W. McNaught, and the shafting from Messrs. T. Robinson and Son, Limited, of the same town. It is worthy of note that in this, as in many other weaving sheds recently erected, the whole of the shafting is of mild steel.

THE RIBBLE NAVIGATION WORKS.—The Local Government Board have issued a memorandum which is distinctly unfavourable to the acquisition of fresh powers of borrowing by the Preston Corporation. They point out that the present debt of the Corporation is £718,494, or twice the amount of the assessable value of the borough, and that if the additional powers are given this amount will be increased to £1,200,000. It is pointed out that the disposition of the sewage is not provided for, and a number of objections are made by the Board, which are in direct opposition to the extension of the present powers. This is a somewhat serious matter, and may result in the suspension of the dock and river works at present in operation.

A SPECIAL DRILLING MACHINE.—Messrs. Hetherington and Co. have just completed a special machine for drilling the mouthpieces of locomotive boilers. As these have to be drilled from the inside, there were considerable difficulties in arranging the drill spindle and feed arrangement. The spindle is held in a circular head stock, which is revolved by means of worm gear below the table; the driving is effected by a shaft also under the bed, and by a short vertical spindle passing up the centre of the head. Bevel wheels on the end of this spindle and the drill spindle give the necessary driving power. The latter is cut at its upper end with a quick threaded screw, on which a long nut with a hand wheel and a brake surface is formed. By applying the brake the nut is held, and the revolution of the spindle necessarily applies the full feed; but if less traverse is required, the brake is only partially applied, and the nut can thus slip a little as desired. The machine is an ingenious one, and is admirably constructed to surmount the practical difficulties of the work. It is made for the Lancashire and Yorkshire Railway Company, Horwich.

LONDON, 22ND MARCH, 1888.

THE MONEY MARKET.—Money is both abundant and cheap just now, and the Bank has recognised this by lowering the official rate. It is assumed that this step was taken to assist the Chancellor of the Exchequer in his Conversion Scheme, for unless money be cheap he cannot maintain over the heads of holders of new Threes the fear of redemption if they refuse to convert. But granting that the Bank was influenced by this consideration, there are abundant reasons for anticipating a continuance of cheap money. The situation, however, will be affected by the impending issue of several new foreign loans. The new Mexican Six Per Cent. Loan, to be issued to-morrow (Friday) at 79, was selling in anticipation on Tuesday at a premium of 1 per cent., so that there is evidently plenty of demand for such securities. The stock markets are distinctly duller this week, and foreign stocks are generally weaker. In spite of good traffic returns, home railway stocks are quiet, and the demand for railway debentures and Colonial securities for investment has abated. Part of the recent rise was unquestionably artificial, though at the same time there was no doubt a considerable amount of sound investment business. Copper shares are beginning to appear again in the market, and diamonds are becoming more susceptible to "bear" influences.

COMPANIES.—The following new companies have been registered since our last report: The St. James' and Pall Mall Electric Light Company, Limited, with a capital of £100,000; the Hull United Brewers, Limited, with a capital of £185,000; the Swaziland Gold Exploration Company, Limited, with a capital of £200,000; Daniel Higson, Limited, with a capital of £100,000, to carry on a brewery; the Victoria Mill Company, with a capital of £3,000, to purchase a cotton mill at Burnley; Anglo-Austrian Tin Company, Limited, with a capital of £90,000; Dunlop and Capon, Limited, with a capital of £50,000, to carry on the business of sawing, planing, moulding, and turning mills; Charles L. Baker & Co., Limited, with a capital of £25,000, to acquire a business of telegraphic, electric, surgical, and scientific apparatus; George Jackson & Co., Limited, with a capital of £30,000, to acquire a tobacco manufacturing business at Whitehaven; the Native Dog Creek Exploration and Mining Company, Limited (New South Wales), with a capital of £5,000; the Mechanical Supply Company, Limited, with a capital of £10,000; the Shaftesbury Automatic Safety Lamp Company, Limited, with a capital of £100,000; Explosives and Ammunition Manufacturing and Testing Works, Limited, with a capital of £10,000; Barrett & Elers, Limited, with a capital of £80,000, to carry on business as manufacturers of bottles, jars, and stoppers; the Patent Indestructible Face Cartridge Company, Limited, with a capital of £10,000; J. S. Warburton & Co., Limited, with a capital of £5,000, to purchase the business carried on at Britannia Iron Works, Preston; J. J. Broadbent & Co., Limited, with a capital of £50,000, to carry on business at Bradford and elsewhere as wool spinners; the Atlanta Gold and Silver Consolidated Mines, Limited, with a capital of £65,000; Sudbury Dairy Company, Limited, with a capital of £40,000; George Hoby & Co., Limited, with a capital of £50,000 to acquire the business of a blacking manufacturer; the British and Irish Gunpowder Manufacturing Company, Limited, with a capital of £50,000; Joseph Mason & Co., Limited, with a capital of £40,000, to take over the business of oil and colour merchants now carried on in Derby; Bradford and District Tramway Company, Limited, with a capital of £60,000; Seaham Chemical Works Company, Limited, with a capital of £20,000; the Dublin Brewery Company, Limited, with a capital of £100,000; Bogaerts' Engraving Company, Limited, with a capital of £30,000; and Canning Town Glass Company, Limited, with a capital of £10,000.

METALS.—An interesting table has been issued by Messrs. H. R. Merton & Co., London, showing the principal copper supplies of the world during the period 1879-87. With the exception of 1886, when the supplies were less than in the two preceding years, there has been a constant increase, and owing to the operations of the copper ring, this year will, no doubt, show a much larger advance. In 1879 the quantity was 151,963 tons, and in 1887 224,490 tons. The average price of the former was £57. 11s., and of the latter £42. 3s. The production of spelter in Europe and the United States rose from 23,239 tons in 1880 to 45,530 tons in 1887; the average price in the former case was £18. 7s., and in the latter £15. 4s.

THE CONDITION OF TRADE.—The Labour Correspondent of the Board of Trade has prepared the following memorandum on the state of the skilled labour market: "The revival which, since the beginning of the year, has been apparent in the shipbuilding trade and in all the branches of the iron and other trades connected therewith, still continues to improve the condition of the labour market of those industries very materially. At the same time it is to be observed that the proportion of unemployed, though relatively much less as compared with the past two years, is still considerable. The building trades are in a very depressed condition, consequent to a great extent on the severe weather of last month, which seems not only to have retarded the usual spring development of the trade, but also to have greatly increased the number of those out of work. The cabinet making and printing trades are good. The cotton and carpet trades are moderate. In the finished iron trades employment is more regular. In the coal trade the number of men actually unemployed is small, but many collieries are only employed about half time. Up to the time of making up the report fifteen trade unions had sent in returns as to unemployed members. With an aggregate membership of 143,879 there were out of work 10,209, as against 11,113 last month, a net decrease of 904, which is a reduction in the proportion from 8·3 to 7 per cent. Three societies state generally trade to be 'good,' one 'normal,' three 'moderate,' seven 'improving,' and one 'bad.' In the trades which have most benefited by the improved circumstances of the labour market, many voluntary advances of wages have been conceded."

ROYAL AGRICULTURAL SOCIETY OF ENGLAND.—In connection with the country meeting of the Society, which is to be held at Nottingham next July, prizes are offered for hay and straw presses worked by steam, horse, and hand power respectively, and for a press for old hay worked by hand power. Intending competitors and exhibitors must make their entries by the 31st inst.

RAILWAYS.—The gross receipts of the twenty-three principal railways in the United Kingdom, for the week ending 11th March, amounted to £1,120,533 on 15,850¼ miles, as compared with £1,111,826 in the corresponding period of 1887, when the mileage was 15,708¾ miles. An increase is thus shown in the mileage of 141½ miles, or 0·8 per cent., and in the receipts of 0·7 per cent.

RUSSIAN CUSTOM HOUSE FINES.—The Foreign Office has issued a notice that as numerous complaints are received from commercial bodies in England of the infliction of heavy fines by the Russian Customs authorities, it is desirable to point out that in many cases fines which are incurred in accordance with the strict letter of the Russian Customs regulations are not enforced; but that, nevertheless, the exporter is charged in the account by dishonest clearing agents as though the fine had really been exacted. It is therefore advisable that in all cases agents should be called upon to produce the official receipts for fines stated by them to have been paid.

THE NAVY.—The gun trials of the new armour plated ship "Hero" have now been completed, and she is ready for sea. She has a displacement of 6200 tons, and her engines are of 6000 h.p.—The trials at Sheerness of the two 110-ton guns of the "Benbow" have proved perfectly satisfactory. Charges of 1000lb. of powder were used, with a projectile weighing 1800lb. The 6in. breech loading guns for the same ship have also been tested with satisfactory results.

BOILER EXPLOSIONS.—A circular has been issued by the Board of Trade to sanitary authorities throughout the country, calling attention to the conviction of the owner of a steam boiler for neglecting to comply with the provisions of the Boiler Explosions Act, 1882, by not sending to the Board of Trade a notice of an explosion which had occurred on his premises. The Board has reason to believe that many owners of steam boilers are still unacquainted with the requirements of the Act, and that consequently explosions sometimes occur which escape investigation. It is therefore suggested that the local sanitary authorities should distribute handbills calling attention to the conviction in question.

FOREIGN EXHIBITIONS.—A meeting was held at the Mansion House last Friday in connection with the formation of the British Section of the forthcoming Paris Exhibition. An executive council has been appointed under the presidency of the Lord Mayor, and preliminary arrangements are in progress.—In connection with the Barcelona Exhibition, the Society of Arts has undertaken to promote the interests of the Exhibition in this country, and to act as the intermediary between British exhibitors and the Executive of the Exhibition. The date for the receipt of applications from foreign exhibitors has already passed, but a request for an extension of the time has been made to the Spanish Executive. In the meantime, British manufacturers who wish to take part in the Exhibition, and have not already sent in applications for space, may apply to the Secretary of the Society of Arts.

GLASGOW, 22ND MARCH, 1888.

INTERNATIONAL EXHIBITION.—It has been arranged that the Prince and Princess of Wales shall open the Exhibition on Tuesday, the 8th May, and that this day shall be observed as a general holiday. The Women's Industries Section is to have a preliminary exhibition of women's work in the Corporation Galleries on Friday and Saturday, the 23rd and 24th inst.

GLASGOW PHILOSOPHICAL SOCIETY: "PREVENTABLE BANKRUPTCY."—An important paper upon this subject was read at a meeting of the Economic Science Section, by Mr. John Mann, jun., M.A.C.A. After describing the difficulties of acquiring accurate statistics of bankruptcy, owing to the frequency of private arrangements, Mr. Mann went on to speak of the effects of bankruptcy upon industry. He estimated the indirect tax upon the nation represented by the whole volume of insolvency at thirty millions per annum at least. The effects of continued trading at a ruinous loss during insolvency were described, and it was pointed out that in consequence of the paralysis to legitimate trading occasioned by it, the practice of selling off bankrupt stocks did not offer an advantage to the public commensurate with the losses entailed. The inevitable result of continued forcing of goods upon the market in this manner was the depression of prices and of trade, the trader who paid his way being compelled to sell his goods at the prices asked for by those who did not pay their way. As to the causes of bankruptcy, Mr. Mann considered that about one-half were causes which could be avoided, the other half being those resulting from general conditions beyond the control alike of individual traders and of Government. The preventable causes were set down as these: Excessive granting of credit, prevalence of rash speculation, defective bookkeeping, &c. The remedies suggested by the author of the paper were: Restriction of the limit of prescription, examination of the bankrupt's conduct by an independent official, as is the case in England, and greater publicity as to the position of a trader.

ENGINEERING.—Messrs. Dunsmuir & Jackson, Govan, have just fitted on board the s.s. "Tropic" a set of triple expansion engines, with cylinders respectively 20in., 33in., and 54in., having a stroke of 36in. The boilers are two in number, and have a working pressure of 160lb. At the trial trip the vessel, with 2600 tons dead weight, attained a mean speed of 10¾ knots. The engines indicated 990 h.p. —Messrs. Sharp, Stewart, & Co., of Glasgow, formerly of Manchester, have disposed of their injector business to the Patent Exhaust Injector Company, Limited, of St. Ann's Square, Manchester. This company have secured the services of the same workmen who served the former owners of the business, so that the manufacture of all classes of injectors will be carried on in the same efficient manner as hitherto.

GREENOCK.—An improvement, if only of a temporary character, seems to have come over the fortunes of the James Watt Dock, Greenock. The quays are now fairly well occupied, considerable cargoes of sugar and wood having been landed during the past few days. The activity which is still manifest in the sugar trade has

Digitized by Google

restored vitality to what appeared to be a decaying industry, and has effected a vast improvement in the trade of the port.

EDINBURGH ELECTRIC LIGHTING.—A specification has been drawn out by Mr. Bryson for the lighting of the Free Library, which is now being erected in fulfilment of the arrangement by which Mr. Andrew Carnegie, of Pittsburg, U.S.A., offered a sum of £50,000 on condition of the Free Libraries Act being adopted by the City of Edinburgh. The specification provides for seventy 16 c.p. incandescent lamps, and twenty-two 1000 c.p. arc lamps. The annual cost, including depreciation, was estimated at £400. The matter was left with a committee to take estimates on the basis of Mr. Bryson's specification.

PLEURO-PNEUMONIA IN SCOTLAND.—A deputation has been received by Lord Cranbrook, President of the Privy Council, concerning the spread of cattle disease in Scotland. This question has become one of great economic importance, since the sum of £34,593 was expended last year in giving compensation under the Contagious Diseases (Animals) Act. It was urged that an inquiry should be made as to whether inoculation should be resorted to. Lord Cranbrook admitted that an indisputable case had been made out for careful inquiry. In the course of his reply, he mentioned that no case of foot and mouth disease had occurred in England for two years, thus affording evidence that slaughtering infected cattle was effectual in extirpating the disease.

(From our own Correspondents.)

LIVERPOOL, 21st MARCH, 1888.

THE MERSEY RAILWAY.—The tunnel from the James-street Station, under Lord-street and Church-street, is now almost bricked in as far as the Central Station, and the excavation is practically completed. The station is being made underneath the Central Station, and as the work is so very near to the surface of the ground at this point, it makes it exceedingly difficult, and the utmost caution has to be taken, on account of the traffic overhead. All the constructional iron work of this station is being made and erected by the Pearson & Knowles Coal and Iron Company, of Warrington.

A NEW EXPORT TRADE FROM THE MERSEY.—Owing to the partial failure of the potato crop in the eastern parts of the United States, an enormous quantity of potatoes have been shipped from the Mersey to supply the deficiency, and very extensive orders are reported on 'Change daily. Since the 2nd inst. about 6000 tons have been shipped to Boston, New York, Baltimore, and Philadelphia; most of these potatoes have been grown in Lancashire and Cheshire. An advance in prices is to be expected shortly.

SHEFFIELD, 21st MARCH, 1888.

THE HEAVY TRADES.—There is no great activity in the armour plate mills or in the gun shops, but for many descriptions of heavy material the demand is very extensive. Crucible cast steel castings are selling well. For almost all kinds of shipbuilding material there is a good market; the competition, however, is keen, and one or two makers have recently lowered their prices. Heavy machinery for foreign as well as home use is more eagerly inquired for, and the engineers are better off for orders than they were at the end of last year. The moulders at the foundries are well employed; while at the rolling mills the quantity of work is steadily increasing. There is a great deal of cutting of prices in steel, and quotations range from £4. 10s. to £4. 15s. and £5. 5s. for rolled billets. In railway material the trade development has been conspicuously steady; and it is worth noting that Messrs. Cammell & Co., Limited, who have paid particular attention to the steel rail departments of their concern, announced on Friday the payment of an interim dividend for the year, making a total altogether of 7½ per cent. Bessemer steel rails are just now in demand, not only for English lines, but Colonial and foreign railways, and it is anticipated that within the next two years there will be an enormous development of railway enterprise. Railway springs, tyres, and axles are being ordered largely, the latter selling at from £6. 15s. to £7 per ton. There is one phase of the steel trade, however, that is not altogether hopeful. Several Australian and other Colonial customers who find it difficult to obtain the quality of steel or the shaped article they require in England, are being suited in America; and it is worthy the consideration of the Sheffield manufacturer whether it would not be desirable to meet the wants of the Colonial customer.

LEEDS, 21st MARCH, 1888.

IRON AND STEEL.—For manufactured iron the call is increasing, and the output at the furnaces is greater than it was at the end of the first quarter of last year. Hydraulic and other machinery is yielding a vast amount of work, and in the locomotive building shops there is more employment. Messrs. Kitson and one or two other noted firms are busy on railway work, and for stationary engines there is a good demand. Bridge work, roofing, and colliery plant are also being extensively ordered, and plenty of heavy manufactured material is being sent abroad. There is a renewed demand for engineers' tools; indeed in most of the heavy branches of Leeds trade an improvement is noticeable.

COAL.—At the West Yorkshire pits the men are working five days a week.

TEXTILES.—There is still some inquiry for woollens, owing to the long winter; but most houses are now busy on summer goods, and there is no lack of employment.

BARROW-IN-FURNESS, 21st MARCH, 1888.

DECLINE IN THE IRON AND STEEL TRADES.—The report of the week in connection with the iron and steel trades of this district is not so satisfactory as of late. There is a weaker tone in the iron trade, and prices have declined to 42s. 6d. per ton for mixed Bessemer samples net f.o.b.; but makers will not, generally speaking, do business at this price. They are fortunately well off for orders, and are likely to be busy for some months on the contracts already in hand. They have also the advantage of a large consumption of pig iron by steel makers in the locality and elsewhere, who are using more iron than at any previous time in the history of the trade; and there is the further prospect of an improvement in the iron trade with the opening of spring and the placing of shipping orders. Steel manufacturers continue to be busy, and there is a good demand for rails; but prices have declined, as also have those of pig iron. Heavy sections of rails are quoted at £3. 19s. per ton net f.o.b. There is not much business doing in steel for shipbuilding material; but makers are well off for orders, and expect large contracts on local as well as on general account. Plates are quoted at £6. 19s. per ton net f.o.b., and angles at £6. 7s. 6d. Billets are in demand at £3. 18s. 6d., and slabs are quiet at £3. 18s. The shipbuilding trade is showing more activity in all departments, and one or two new orders are noted. Iron ore is in quieter demand at lower prices, viz., 8s. to 11s. per ton net at the mines.

JUTE.—Great activity is maintained in the jute trade of Barrow, and the mills are regularly employed.

THE TIMBER TRADE.—The timber trade of the port of Barrow has been very quiet for about two years; but a much better year is expected in 1888, as the general demand shows some indications of improvement, and local requirements will certainly increase.

SOUTH WALES, 21st MARCH, 1888.

NEW DOCK AND CANAL—There is a somewhat bold scheme being mooted by a powerful London syndicate to construct a dock at the mouth of the river Rumney, at Cardiff, with a ship canal, about two miles long, to be connected with it. Works would be erected on each side of the canal, and so bring business to the company. It is roughly estimated that the scheme would cost about £1,000,000; but as there is a large demand springing up for sites for industrial purposes, it is confidently maintained that its success is assured if only the opposition of the Bute Docks Company can be overcome.

SOUTH WALES INSTITUTE OF ENGINEERS.—A well attended meeting of this Institution was held on Thursday last, at Cardiff, under the presidency of Mr. Archibald Hood. The chief attention was devoted to electric safety lamps, the use of which is making rapid progress. Mr. Nicholson, of the New Electric Portable Electric Light and Power Syndicate Company, exhibited two lamps, which only weighed 4lb., and which would burn from ten to twelve hours, giving a light equal to one and a quarter candles. The front of this lamp is fitted with thick toughened glass, and if that is broken by any accident, the light is at once automatically extinguished. Mr. Swan, who will shortly have 2400 of his lamps in use in this district alone, stated that his lamp weighed about 7lb., but, of course, could be made lighter if desired, at the sacrifice of illuminating power.

AGRICULTURAL.—A local committee has been formed at Swansea, to make arrangements for the show of the Glamorganshire Society on the 1st and 2nd August, when a large number of special prizes will be offered for competition. A hide and skin market is to be established at Cardiff for the disposal of these commodities by public auction, on the plan which has been found so profitable by the trade in some Midland towns. The capital has been fixed at £3,000.

MIDDLESBROUGH, 21st MARCH, 1888.

PIG IRON.—The market still remains unchanged, and there is sufficient probability of a forward movement to prevent any fall. The average price amongst merchants is still 31s. 6d. per ton for No. 3 G.M.B. for early, and 31s. 9d. to 32s. for April-June delivery. Warrants are 31s. 4½d. to 31s. 6d. per ton (cash) for Connal's No. 3 G.M.B., and 42s. 6d. nominally for Connal's Nos. 1, 2, and 3 hematite. Makers of hematite East Coast brands are quoted 43s. 6d. per ton f.o.b. mixed numbers.

SHIPMENTS OF PIG IRON.—These are far from favourable. Those to Scotland and other parts of England remain about the same, but those to foreign ports have fallen off. Up to the 19th they have declined about 4000 tons over the current month as compared with the similar period in the previous month.

FINISHED IRON AND STEEL.—The revival in the wrought iron trade continues. The steel works are going steadily, especially in the plate departments. There is also a large turn out of rails and sleepers, but the former have fallen very much in price; £4. 17s. 6d. per ton ordinary sizes is the average lowest, but lower still in some cases has been accepted.

STEAM SHIPPING.—There is a more healthy freight market this year than there has been for many years back. Well managed, economically worked steamers have paid at the rate of 10 per cent. and upwards per annum on their original cost. Second hand boats, acquired at cheap prices during the past two years, have paid as high as 30 per cent. on the capital invested.

SUNDERLAND, 21st MARCH, 1888.

COMPOUND STEAM WINCHES.—Messrs. Wigham & Co., of the South Hylton Engine Works, have just completed their first four steam winches on the compound principle. The working pressure of the steam supplied to the high pressure cylinders is 150lb. per square inch, and the diameters of the cylinders are respectively 6¼in. and 9in. The exhaust steam passes to a condenser placed in the donkey stoke hole, and is utilised for feed water for the donkey boiler, as in the ordinary marine engines. There is also the advantage of no exhaust steam escaping on deck, to the discomfort of the cargo men. It is anticipated that these compound steam winches will come into general use, as they can be worked from the main boilers without the interposition of a reducing valve.

THE SHIPPING TRADE.—Owing to the stormy weather last week there was a considerable falling off in the arrivals and departures in the Wear. There was only one cargo of iron ore imported, and the coal shipped was only 68,247 tons, as against 88,615 tons in the previous week, and 75,499 tons in the corresponding week of last year. Of the whole quantity shipped, 49,326 tons were for home ports, and 18,921 tons exported. The other principal shipments were 23,000 dozen bottles, 2512 tons patent fuel, 200 tons coke, 30 tons hoop iron, besides glass and earthenware.

NEWCASTLE, 21st MARCH, 1888.

CHEMICALS.—At the beginning of the present month a new restrictive measure in connection with the manufacture of bleaching powder was put in force in the principal Tyne chemical works, reducing the aggregate output of commodities by about one-fourth. At the Jarrow Chemical Company's works, Felling, the weekly make was reduced from 120 tons to 90 tons, and in this instance, as well as at the other establishments, a large proportion of the operatives have been rendered idle. The manufacture of soda, an article for which there is an active demand just now, has increased considerably within the period indicated, the output of this commodity at the factory that has been especially referred to having in the fortnight ending March 10th reached the large figure of 1240 tons. This is the largest output ever attained at this factory in the time mentioned. The company are now about to put down plant for the establishment of a new process, viz., the recovery of sulphur from alkali waste, and measures are in contemplation for the carrying out of a similar project at the Newcastle Chemical Company's works, Gateshead. The demand for alkali is somewhat below the average, and at most of the works stocks are accumulating.

CEMENT.—The leading manufacturers of cement in the district have just now some heavy orders to execute, the commodity being mainly sought after by consumers on the other side of the Atlantic. There is, however, a lack of tonnage suitable for this kind of cargo, and the export trade at this moment is, therefore, not particularly brisk. The demand on home account remains good, and the factories are all very fully employed.

COPPER.—Business is still very brisk in the copper refining works, and present appearances indicate a continuance of this satisfactory state of matters.

LEAD.—The demand for sheet lead has somewhat improved, but in other respects there is little change to be noted at the lead manufactories.

THE COAL TRADE.—The recent bad weather, though it must have had a stimulating effect on the demand for house coals, has caused increased slackness at most of the steam coal collieries, the arrival of vessels wanting cargoes having been unusually small. The shipments of coal and coke from Tyne Dock, for the week ending March 17th, amounted to 75,359 tons, which quantity was less by over 14,000 tons than the aggregate shipments of the same commodities in the corresponding week of 1887.

BELFAST, 21st MARCH, 1888.

MONEY.—Consequent on Mr. Goschen's financial scheme, there has been more excitement on the Dublin Stock Exchange than has been witnessed for twenty years. On the 14th inst. Bank of Ireland Stock opened at 287, and closed at 294. Great Southern and Western Railway rose 3½, and other railways from 1 to 1½ per cent. The principal activity, however, was in Debenture Stocks, which were in great demand at improved quotations. During one week Bank of Ireland Stock has risen £25.

SHIPBUILDING.—Great activity is still the rule here, and some new orders have been booked within the last fortnight; rapid progress is being made with the vessels on the stocks. The Belfast Harbour Commissioners invite tenders for a new steel steam ferry, with fire engine.

LINEN TRADE.—Business is rather quiet. Coarse wefts are rather dull at late prices, but the higher numbers have a ready sale at slightly advanced rates. The stocks of tows in hand are small, and trade is flat. Brown goods are steady, with all the looms fully employed. The demand for cloth and finished linens continues steady at late prices. The demand for handkerchiefs is brisker, and the prices have advanced somewhat. Shirt makers are fully employed, and hold large orders for immediate and forward delivery.

Advertisements intended for insertion in the current week's issue must reach the Manchester Offices not later than first mail delivery on Thursday morning. Scale of charges for displayed advertisements on cover and inside pages will be forwarded on application. Orders for single advertisements must be accompanied by payment in order to insure insertion, the charge for which is 2s. 6d. for the first four lines or under, and 8d. for each additional line; one inch and over at 7s. per inch; the line averages eight words. While all practical regularity in the insertion of serial advertisements will be observed, it can only be absolutely guaranteed in the case of those ordered to appear weekly.

All accounts are payable to the Publisher, JAMES F. BUTTERWORTH, *70, Market-Street, Manchester. Cheques should be crossed Manchester and Liverpool District Bank, King-street Branch, Manchester. Post Office Orders to be made payable at Manchester.*

To Correspondents.

All communications intended for insertion in this Journal, or relating to Editorial matters, should be addressed to "THE EDITORIAL DEPARTMENT," either at the Manchester or the London Offices, and must, in all cases, be accompanied by the name and address of the writer. No notice will be taken of anonymous letters.

We cannot undertake to return manuscripts or drawings, and must request correspondents to keep copies.

Industries, VOLS. I., II., & III.

From July, 1886, to December, 1887.

A few Copies, handsomely bound in half calf, gilt lettered, may now be had at the Head Office, 70, Market-street, Manchester, Price 20s. each.

Industries:

FRIDAY, 23RD MARCH, 1888.

NAVAL ADMINISTRATION AND ORGANISATION.

IF the administration and organisation of the naval, military, and civil services do not improve, it will not be for the want of very candid criticism. Such men as Lord Randolph Churchill and Lord Charles Beresford do not hesitate to use the knowledge they gained when in office, when they find themselves in positions of greater freedom and less responsibility. The former must have made some of the occupants of comfortable Civil Service berths feel somewhat unhappy. It is, however, to the remarks of the latter, and the affairs to which they relate, that we wish in the meantime to direct the attention of our readers. In the recent debates on the Navy Estimates, with all the breezy frankness of a sailor, he let the public into some of the secrets of official life. He protested that it was not simply the small matter of the cutting off of £900 from the allowance for the Intelligence Department which caused him to resign, but rather the system which allowed the reduction to be made in the way it was done. He stated that before the present Board took office there was no shred of system of any sort for organisation for war, and he maintained that this statement was substantiated by the memorandum issued by the First Lord last year, and also in this year's memorandum in the paragraph dealing with the experimental trial of the system at Portsmouth. This, however, only referred to mobilisation, and he challenged the First Lord to produce any plan of campaign for home or abroad; any plan for the coaling of the fleet, for the protection of the mercantile marine, or any organisation for war—excepting that on paper—which the First Lord had himself described as being most defective. The Intelligence Department, which was the immediate cause of his rupture with the Board, was essentially a naval question, as was indeed everything connected with the organisation required for war, and the manner in which it was now managed was most unbusiness-like. With regard to the Estimates, there was no real Treasury or Parliamentary control over them, and he illustrated this by an incident in his own official career. He stated that one morning the Estimates were brought into his room by a clerk with a wet pen. "What is that?" Lord Charles asked. "The Estimates," the clerk replied. "What do you want me to do?" he further inquired. "I want you to sign them," was the reply. To that he rejoined "Certainly not," as he felt that if he signed them the public would assume that he had studied them, and that he was satisfied with them. As a matter of fact he had not read or studied them, and he was not at all sure that he was satisfied with them. The fact, however, that the clerk brought in the pen wet with ink showed that this was not the usual method of procedure. With regard to the information contained in the memorandum of the First Lord, he confirmed the opinion which is generally held by the public, but which is not often openly expressed, that it was all derived, not from the First Lord's own knowledge—for he could not, and did not know anything about it—but from the experts. Lord Charles concluded his speech by advocating a series of reforms, which may be briefly summed up as follows: That all the naval business should be under the direct control of the sea lords; that the Intelligence Department be made effective, with an admiral at its head; that both on the Board and in the Secretarial Department arrangements be made for an infusion of new blood, so that advantage might be taken of the latest and best experience; and, lastly, that there should be a more complete organisation for war.

Like a great many other enthusiasts, Lord Charles Beresford overshot his mark in some respects, as he sought to prove too much, and he proved himself a good example of the danger of appointing a naval man as head of the Admiralty. Some of his suggestions no doubt were excellent; but, as Lord George Hamilton pointed out, this special proposal was to be condemned both on theoretical grounds and from practical experience. He was of opinion that the House was not likely to sanction the principle of a naval officer being *ipso facto* a member of the Legislature because he was the head of a great spending department. Even if the House did accept the principle, he thought the result would be rather to introduce politics into the navy than to secure an addition of naval knowledge at the Admiralty. He was not certain that in France, for example, the system advocated had been altogether a source of stability. He had listened last year to a discussion in the French Chamber, when charges, graver than any that had ever been made in the House of Commons, were made against the administration of the French Navy. There was an absolute consensus of opinion on this subject, that the result of putting at the head of the Admiralty a naval expert was that he had rushed into expenditure on a number of projects that had not been sufficiently tested, and had seriously jeopardised the position of naval finance in France. The speakers who took part in the discussion of the Naval Estimates proved most distinctly that there is a danger of the Admiralty falling into the hands of experimentalists and faddists, and millions might be spent on alarms and scares. None of them had any general policy, but they were all of opinion that the navy will never be strong unless their views are carried out. But any unbiassed observer can see at once that these are one-sided views, and therefore we require at the head of the Admiralty a man of good sound common sense, who would be able to weigh carefully the importance which should be attached to any suggestion which may be made.

The First Lord of the Admiralty maintained that the Admiralty had now adopted a consistent policy, and that every year will make our navy stronger than it is or has been. This statement ought to be compared with that which we gave in our last issue —page 261. He stated on the 1st of March, 1887, that we had in commission sixteen ironclads, with an aggregate tonnage of 127,000; and in reserve, five, with an aggregate tonnage of 44,000. France had five war ships, of 79,000 aggregate tonnage, in commission, and six with 40,000 tonnage, in reserve. Italy had two in commission, and two in reserve, with a tonnage of 41,000. Russia had one ironclad in commission and four in reserve, the tonnage being 25,000. During the present year our first reserve, which could be put into commission in forty-eight hours, had a tonnage of 46,000, as against 14,000 in the case of France, and 13,000 in the case of Italy. Next year, by carrying out the programme laid before the House, we should pass out 53,000 tons. France, in the same time, would have 29,000, Italy 32,000, and Russia 26,000; and at the end of March, 1890, we should have 311,000 tons, against 184,000 in France, 100,000 in Italy, and 73,000 in Russia. He believed he was well within the mark when he said we were from 30 to 40 per cent. stronger

Digitized by Google

than the next strongest Naval Power. Therefore we were justified in assuming that our relative superiority, in so far as fighting was concerned, was established, and that if we continued our programme, we would secure, year by year, a greater degree of superiority. If we were advancing cautiously, it was because there was great divergence of opinion among naval authorities as to what ought to be done. On the subject of the relative values of the navies of this country and the Continent, Mr. Fitzgerald stated he had the opinion of an expert, who had made the following estimate. Taking Britain at 100, then France would be 90, Italy 50, Germany 40, and Austria 31. We must leave the discussion of these figures for the present, but on the general question of sufficiency the First Lord remarked that the greatest danger was where the largest stream of commerce passed nearest the land, which would afford protection to hostile cruisers, and the policy of the Government was to husband their strength by having a large force in reserve, and it was opposed to the wholesale building of vessels, because they would all become obsolete at the same time.

Turning from the discussion of the Estimates themselves, we have much pleasure in observing the improvement in the form in which they are presented, and that the policy inaugurated last year by the Board of laying before Parliament fuller details relating to naval expenditure has been continued. In carrying out this object it is stated that the following are the salient points which the Board has endeavoured to meet: (1) To preserve, as far as possible, continuity of practice, in order to allow comparisons being made with the expenditure of the previous year; (2) to show the product anticipated from the expenditure, especially as regards dockyard work; (3) to exhibit the aggregate cost of each branch of the service, under whatever vote or department of State the provision may, in part or whole, be made; (4) by abolishing appendices, to bring the detailed appropriation of expenditure into direct connection with the votes, that it may be brought under the scrutiny of the Controller and the Auditor-General. If these arrangements be carried out, the public will for the first time have before it the total expenditure upon each branch of the Naval Service, and information as to the items of which it is composed. We have thus separate statements of the full cost of the *personnel* of the Fleet, including wages, provisions, medicines, half-pay, and pensions, and we find that the total cost of this department amounts to no less than £6,300,000, or one-half of the total estimated Naval Service. Similarly, we have estimates for shipbuilding, repairs, maintenance, &c., and we shall thus be able to ascertain, not merely the total cost of the dockyards, including establishment charges, as well as labour and stores, but of the proportion of these several charges to be set to the account of the individual ships under construction; and it will be possible to compare directly the cost of a ship built in a dockyard with that of a ship built by contract. The recent reforms in dockyard administration have had considerable effect on the cost of work done, and the First Lord is able to state that "the rapidity of construction shown in the advance of the ironclad 'Trafalgar' has rivalled, if not beaten, the best record in private shipbuilding yards," while the repairs of the "Northumberland" were estimated by the dockyard at £45,000, and they were actually effected for £22,000—and a long list of similar reductions is given. It would, however, have been more to the point if the Estimates had been made by independent parties, for it is a comparatively simple matter to make an apparent saving if the dockyard officials are not controlled in any way in the figures they put down in the Estimates. The figures quoted above for the "Northumberland" may only prove that the original estimate was far too high. There can be no doubt, however, that considerable economies have recently been effected in the method of doing work at the dockyards, and the First Lord, commenting on this part of the subject, said: "It is noteworthy that hardly any recent estimate, which after careful examination by the Controller's officers was reduced, has subsequently been exceeded in the yards; but that as a rule there have been substantial savings even upon the reduced amounts. This proves that the dockyard officials are now heartily co-operating with the central authorities, and are watching carefully the working out of estimates and the cutting down of unnecessary expenditure." As the *Times* remarked the other day, the word "now" in the foregoing sentence speaks volumes. In plain English it means that for years past the money of the British taxpayer has been scandalously wasted in Her Majesty's dockyards. That there is still room for economy is shown by some of the figures contained in the Estimates. For instance, at Sheerness the cost of superintendence to work done is nearly 15 per cent., whereas in the other yards it is only 10 per cent., and the sheathed protected cruisers, "Magicienne" and "Marathon," which are being built by the Fairfield Company, Glasgow, are put down at £140,000 each, while the corresponding estimate for the construction in one of the dockyards of the "Melpomene," a sister ship, is no less than £161,000.

While, therefore, giving credit for the improvement which has undoubtedly taken place, we would urge continued vigilance, so that neither the Dockyard nor the Admiralty authorities should be allowed to fall back into their ancient methods of doing work and keeping accounts. We would further urge the necessity of putting the Intelligence Department into a thoroughly efficient condition, and making it an adequate organisation for the contingency of actual war.

THE REGISTRATION OF ARCHITECTS, ENGINEERS, AND SURVEYORS.

One of the tendencies of the present day is without doubt an increasing belief in the efficiency of Acts of Parliament, and the edicts of Government Departments. Yet to those who know anything about Parliament or Government Departments, such a tendency is incomprehensible. The decisions of Parliament are not always guided by a full knowledge of the subjects under discussion, and, consequently, are wanting in that philosophic depth which should mark all wise legislation. The edicts of Government Departments are very often the whims of the permanent officials. As the *Times* remarked the other day, "People fancy that the Treasury means one or two responsible politicians at the head of affairs. To some extent it does; but to a great and most dangerous extent it means nothing more than a clerk at a desk, who, by initialling, reporting, and procrastinating, blocks half the business of the country, and breaks the heart of every man who has real public work to do and tries to do it." And yet people will go on invoking the aid of Parliament in things which they ought to be able to manage perfectly well by themselves, or at least with the aid of those associated with them. Government should not be allowed to interfere in the affairs of the people unless there was a very clear case that such interference was necessary for the protection of those who were too weak to protect themselves, or where a concern—such as, for instance, the Post Office—can be carried on efficiently, so that the whole nation may benefit. The aim of all wise legislation should be to encourage a voluntary co-operation which will habituate men to independent activities, instead of rendering them the slaves of fixed rules and regulations, and which, while strengthening their own consciousness of personal rights, will show them that those rights can only be enforced when they respect the just claims of others.

These thoughts have called forth expression owing to the receipt of a Bill which has been introduced into Parliament to arrange for the qualification and registration of architects, engineers, and surveyors, and its object is stated to be to enable persons requiring professional aid in architecture and engineering or surveying, to distinguish qualified from unqualified practitioners. This no doubt is a very worthy object; but in our opinion it does not require the passing of an Act of Parliament for its accomplishment, if the voluntary associations already in existence only took the steps they ought to take in order to raise the status of their members. The Bill which we are about to notice has for its short name "The Architects' Registration Bill," and this and its whole tenor show that it has been got up by architects for the benefit of architects, and that the engineers and surveyors who are mentioned are those general geniuses so well known in connection with building estates in the neighbourhood of London and other large towns, and of whom many representatives are to be found in country districts, who combine in one person the ability to survey the ground, plan the house, and lay out the drains. The Bill graciously says that "the Charters of the Royal Institute of British Architects, the Institution of Civil Engineers, the Royal Institute of Architects (Ireland), and the Surveyors' Institution are hereby confirmed, and are declared to be and shall be in full force and virtue, except so far as the same are by this Act altered, or as the same are inconsistent with this Act." The Council of the Institution of Civil Engineers must feel relieved by this information; but we doubt if the promoters of the Bill fully realise the powers conferred by the Charter of that Institution, or at least their extent as developed by the requirements of modern engineering. That document says that the Institution was formed "for the general advancement of mechanical science, and more particularly for promoting the acquisition of that species of knowledge which constitutes the profession of a civil engineer, being the art of directing the great sources of power in nature for the use and convenience of man, as a means of production and of traffic in States both for external and internal trade, as applied to the construction of roads, bridges, aqueducts, canals, river navigation, and docks for internal intercourse and exchange, and in the construction of ports, harbours, moles, breakwaters, and lighthouses, and in the art of navigation by artificial power for the purposes of commerce, and in the construction and adaptation of machinery, and in the drainage of cities and towns." The present membership of the Institution includes men who have had experience in every department of what is usually called civil engineering, and, in addition, mechanical, electrical, mining, chemical, and metallurgical engineers, as well as naval architects and shipbuilders. Are the promoters of the Bill prepared to take all these under their kind protection? Speaking of promoters, we naturally turn to the back of the Bill to find out who they are, and we see the names are Colonel Duncan, Captain Penton, Mr. Murphy, General Goldsworthy, and Colonel Makins. But we naturally ask, Under whose instigation are these men acting? Do they represent the opinions of the great body of engineers or of architects, or are they only the mouthpiece of a comparatively insignificant Society? Rumour has it that the Bill is really promoted by the Society of Architects. Now, we do not wish to say one word against that Society; but we must decline to recognise it as the *mouthpiece* either of the engineers or the architects of the country. If the Institution of Civil Engineers had united with the Royal Institute of British Architects in asking powers similar to those proposed in the Bill, the demand would have been worthy of serious consideration; but, so far as we can understand, these Institutions are at present simply ignoring the Bill as beneath their notice, although they may be reserving their strength till it appears whether there is any need for exercising it, and they may think that the very pretentiousness of the Bill will kill it.

We will not in the meantime occupy too much space with its consideration, but will simply give a brief outline of its scope. It ordains that a Council, which shall be styled "The General Council of Architectural, Civil Engineering and Surveying, Education, and Registration of the United Kingdom," shall be established, with branch Councils for England, Scotland, and Ireland. Five members of this Council are to be nominated by Her Majesty, five by the registered practitioners, and sixteen by various representative Institutions. A register is to be kept, and every person who at the date of the passing of the Act is a fellow, member, associate member, or professional associate of any of the bodies mentioned in a schedule attached to the Act, or who is an associate of the Royal Institute of British Architects, shall on payment of a fee not exceeding £3 be entitled to registration. The names in the schedule are worthy of note. Architects' associations of all sorts and sizes are mentioned, but some very important engineering institutions are altogether omitted. For instance, the claims of Scotland are recognised only in the Glasgow Institute of Architects, and the Glasgow Architectural Association. This latter Association is made up of young men who, as a rule, are too young for admission to the Institute of Architects. Whether it should be recognised or not is not now the question; but surely the promoters have heard of the Institution of Engineers and Shipbuilders in Scotland? The Scotch engineers have shown that they are not altogether to be despised. Having once been admitted to the register, members will be required to pay in advance an annual renewal fee of ten shillings. An unregistered person who takes or uses any of the names, titles, or descriptions mentioned in the Bill, shall be liable, on summary conviction, to a fine not exceeding £20, and on repetition of the offence, £50. We need not enter in the meantime into the details of the arrangements which are proposed for the admission of future engineers to the register, but will only remark that examinations are to be conducted by Institutions and Universities under the supervision of the Council. We shall, however, watch any further progress of the Bill with some interest, and

Digitized by Google

observe the arguments its promoters bring forward in support of it. We would, however, remark that the Bill is a sign of the times which the existing Institutions should not by any means ignore; but, on the contrary, should so modify their arrangements as to make legislation unnecessary. On another occasion we hope to indicate the directions which, in our opinion, these modifications ought to take.

CANAL EXTENSION.

THERE are two recognised facts with regard to the incidence of water and railway carriage. As a rule, heavy goods may be more cheaply, but less expeditiously, conveyed by water than rail, and a healthy competition between the two modes of conveyance results in a fair tariff of rates. Amongst traders it is also recognised that in landlocked positions, where no such competition exists, the result of railway monopoly is to be found in the imposition of the highest "charge the traffic will bear," which is disastrous to industrial prosperity. At the present time considerably more than half the existing canal mileage is under railway control, and in many cases the acquisition of this property has been in excess of the rights granted to the companies by Parliament, and in distinct contravention of the recorded purposes of the original owners. A joint committee of the Houses of Lords and Commons, which sat in 1872 to consider this subject, reported: "That no inland navigation now in the hands of a public trust shall be transferred to, or placed under the control of, a railway company. That if the trustees of an inland navigation, or a canal company, apply to Parliament for power to compulsorily purchase a canal from a railway company, such purchase shall be favourably considered by Parliament, and that the utmost facilities shall be given for the amalgamation of adjoining canals with one another, or with adjoining navigation;" and in the Government Bill now before the House of Lords, there is a provision to prevent the future unauthorised application of railway funds to the acquirement of canals. The diverse ownership of different sections of the same canal is detrimental to securing easy through rates. No less than nine companies own the canals between Liverpool and London, while in the communication between North and South Staffordshire rates have to be obtained from and paid to three different companies. A result of the ownership of railways and canals in the same district by one company is that rates are not regulated to meet the exigencies of trade, but of the respective properties. They are so apportioned as to encourage the concentration of traffic on the length—railway or canal, as the case may be—from which the company in question receives the highest proportion of the through charge. A comparison between rates of carriage which prevail in those Continental countries where canal communication has been developed, with those exacted for the conveyance of goods to the seaboard from inland centres in this country, exhibits a startling difference, all in favour of our competitors. One example, culled from a pamphlet published by Mr. Samuel Lloyd on this subject—to which we shall have occasion to make further reference—will suffice. The Belgian iron masters of Liège and Seraing pay 2s. per ton for the conveyance to Antwerp, in craft carrying 300 tons or more, of their manufactured iron and steel for export; whereas the rate paid on English iron from Staffordshire to London is more than six times that amount, but, if framed on the basis of the Belgian tariff, would be only 3s. per ton. It is very evident that the tendency of such an impost in these days of fierce foreign competition and low prices must be to either annihilate the trade of the Midland counties or transfer it to seaboard localities. From the recent abortive legislative ventures in this connection, it is equally apparent that the only remedy for this state of things is to be found in the prompt development, by those interested, of competitive water communication with our principal export centres. Manchester has boldly led the way, and its Ship Canal scheme is in process of accomplishment. It now remains for Birmingham, situated in the very centre of England, with no important seaport less than one hundred miles distant, and which may be regarded as the Metropolis of the Midlands, to decide upon some feasible scheme for the reduction of those heavy transport rates which now handicap the trade of the Black Country and Mid-England generally, not only in competition with foreigners, but with other home centres, the more favourable situation of which allows of similar productions being placed on the seaboard at a nominal cost. More than a century has elapsed since the existing Birmingham Canal was cut through the South Staffordshire coal field and connected with the Wolverhampton Canal. During that period the trade of the district has passed through many vicissitudes until, to those behind the scenes, it is now abundantly manifest that the staple industries of colliery working and iron making are dwindling into comparative insignificance, and stand sorely in need of the removal of all drawbacks to their resuscitation; and particularly that of heavy railway charges on export goods. For something like two years this latter phase of the industrial situation has engrossed the attention of public opinion in Birmingham, and in April last the Ship Canal Inquiry Committee was appointed by the Town Council to inquire primarily into a scheme, to which the attention of the Council had been formally called, for an enlargement of the Birmingham and Worcester Canal to a sufficient capacity to carry seagoing vessels of 200 tons, in connection with improvements on the Gloucester and Berkeley Canal; and, finally, into the merits of any scheme for improving canal communication with London, Liverpool, or other ports.

THE PRODUCTION OF COAL IN 1887.

THE returns of the production of coal in the United Kingdom during 1887 have just been compiled at the Home Office, by the inspectors of mines, and advance copies have this week been sent out by the Board of Trade. It appears that the total production of coal in 1887 was 162,119,812 tons, as compared with 157,518,482 tons in 1886. There was thus an increased production in 1887 of over 4,500,000 tons. The chief item of increase appears in the South Wales district, where it amounts to 1,932,000 tons, and where the total output was 25,977,000 tons. The next largest increase was 1,111,000 tons in Scotland, where the output of coal in 1887 was 21,848,000 tons. Large, however, as was the output of coal in 1887, it was under that of the year 1883, when 163,737,000 tons were produced, so that the past year has not by any means witnessed the highest yield from our coal mines. The twenty coal fields into which the country is mapped show an increased production in fourteen and a decrease in six. The greatest falling off has occurred in the Northumberland coal field, and it is attributable to the serious strike which took place there in the early part of last year. This strike has reduced the production and consumption of Northumberland steam coal to the extent of 1,647,000 tons, and explains the very considerable increase of production in the coal fields of Scotland and South Wales, amounting together to over three millions of tons. There has also been a reduced production in Gloucestershire, Leicestershire, Somersetshire, and Worcestershire, and, to a smaller extent, in Cumberland. The output of the principal districts is shown in the following table:—

Statement showing the production of Coal in the principal coal producing districts in each of the years 1887 and 1886 (1=1000 tons):—

	1886.	1887.	Increase in 1887.
South Wales	24,045	25,977	1,932
Scotland	20,373	21,484	1,111
South Durham	20,112	21,003	891
Lancashire	20,574	20,768	194
Yorkshire	19,392	20,109	717
Staffordshire	12,438	12,853	415
Derbyshire	8,908	9,063	155

In Ireland there has been an increase of about 2000 tons in 1887, the output having been 107,000 tons in that year, against 105,000 tons in 1886.

The total number of persons employed about the coal mines of the United Kingdom in 1887 was 526,277, as compared with 519,970 in the previous year. Of the number employed in 1887, 428,540 were employed above ground, and 97,737 under ground. The number of employés in each principal district, with the quantity of coal produced and the average annual production per employé, is shown in the following tabular statement, from which it appears that Staffordshire stands first, North Durham second, South Durham third, and East Scotland fourth:—

	Tons Raised.	Employés.	Tons Raised per Employé.
Great Northern Coal Field:			
South Durham	21,003,629	55,445	378
North Durham	7,854,492	20,463	383
Northumberland	5,658,940	25,705	220
Cumberland	1,796,594	6,889	260
Totals and average	36,313,655	108,502	334
Welsh Coal Field:			
Glamorganshire	17,410,000	62,059	280
Monmouthshire	6,796,306	21,329	323
Carmarthenshire	556,835	2,200	253
Totals and average	24,763,141	85,588	283
Scotch Coal Field:			
East Scotland	15,268,186	42,196	363
West "	6,216,790	18,868	345
Totals and average	21,484,976	61,064	353
Lancashire Coal Field:			
North & East Lancashire	9,786,927	31,466	315
West Lancashire	10,981,491	33,887	333
Totals and average	20,768,418	65,353	320
Yorkshire	20,104,713	66,904	305
Derbyshire	9,063,407	29,737	312
South Staffordshire	8,173,901	19,377	430
North "	4,679,000	15,503	312

The increase in the quantity of coal produced in the United Kingdom during the last twenty years has been 59,584,000 tons, an increase equal to more than the total production of the whole of Continental Europe at the present time, excepting Germany. The greatest increase has occurred in the South Wales district, if we reckon Monmouthshire and Glamorganshire as one coal field. Here the development in the twenty years has exceeded 12,000,000 tons; or, in other words, has all but doubled. The next most important development has occurred in the Yorkshire coal field, where the increase has been over 10,250,000 tons; and the third place falls to the Durham and Northumberland, or Great Northern coal field. Particulars of each district are appended:—

Statement showing the quantities of Coal raised in the United Kingdom, and in each district thereof, in 1886 and in 1887 (1=1000 tons):—

District.	Production of Coal In 1886. Tons.		In 1887. Tons.	Increase In 1887. Tons.	Decrease In 1887. Tons.
Durham & Northumberland	25,194	34,515	9,321		
Cumberland	1,490	1,796	306		
Yorkshire	9,715	20,109	10,394		
Derbyshire	4,750	9,063	4,313		
Notts	1,600	5,596	3,996		
Leicestershire	866	1,099	233		
Warwickshire	775	1,456	681		
Staffordshire & Worcestershire	12,298	13,698	1,400		
Lancashire	12,320	20,768	8,448		
Cheshire	895	733			162
Shropshire	1,221	771			450
Gloucestershire, &c.	1,851	1,261			590
Monmouthshire	4,445	6,796	2,351		
South Wales	9,376	19,179	9,803		
North Wales	2,082	2,780	698		
Scotland	12,625	21,484	8,859		
Ireland	124	107			17
Totals	101,627	161,211	60,803		1,219
Deduct Decrease			1,219		
Net Increase in 1887			59,584		

BASIC STEEL FOR BOILERS.

A CERTAIN amount of suspicion pervades the minds of engineers in general with regard to the use of basic steel for boilers, and perhaps there is sufficient justification for this feeling of distrust, as accounts are reported of the erratic behaviour of basic steel plates in boilers and in other situations. The Committee of Lloyd's Register, some time ago, forbade the use of basic steel for shipbuilding; though they now sanction the application of it for ships and marine boilers, where it is made by methods of which they approve. For example, we reported a short time ago that the Glasgow Iron Company's steel was approved by Lloyd's Committee. The basic steel made by the Bessemer process seems to be that which is chiefly at fault. Much more uniform results are generally being obtained by the basic Siemens or basic open hearth process. In another column we give some particulars of a law suit raised by the Snedshill Iron Company, who supplied basic Bessemer steel plates to a firm in Staffordshire for boiler making purposes, and it may be interesting to refer to one or two of the points raised. The boiler makers requested that some of the plates should flange and weld; but they seem to have been quite unsuitable for any such manipulation, and the steel makers had, according to the ruling of the judge, to deduct from the invoice, not only the value of the particular plates in question, but the cost of removing and replacing the defective plates which had been worked up and put into boilers. This ruling appears rather severe upon the steel makers, since some may consider that the boiler makers should have been held responsible for putting imperfect material into the finished boilers. They apparently had it entirely in their own hands to use the plates in question or put in other plates. The plates which failed were those in the cross tubes, which the boiler makers had only been able to complete by dint of "patching and mending" the flanges and welds. Regarding plates for the shells and fire boxes of the boilers, no complaint had been made until after proceedings had been taken, so that the judge would allow no claim with respect to defects in these, although some direct evidence of imperfections in these was given, but more particularly with regard to the analysis of the steel. One contention relating to the analysis, put forward by the steel makers, is worthy of notice, viz., that ·24 of oxygen could not co-exist in the steel with ·11 of phosphorus and ·51 of manganese. Mr. Tucker, who made the analysis, considered that such a result is quite possible in steel. If, for instance, sufficient free lime is not present in the converter during the "after blow," the "blow" will oxidise the steel instead of removing the phosphorus; and if sufficient time be not given to the manganese, which is put in after blowing, to enter into combination with the oxygen in the charge before casting, the latter

Digitized by Google

element will remain combined with the steel as oxide of iron. Another explanation of an apparently anomalous analysis such as the above lies in the possibility of the ingots being so honeycombed that oxidation may penetrate very far below the surface during the heating at the rolling mill furnaces; so that notwithstanding the fact that the scale was removed before taking drillings for analysis, the oxide present internally would affect the result seriously, and yet not have been in chemical combination with the charge of steel in the converter. Mr. Tucker stated that he found the steel "red short," which was probably due to an excess of oxygen and sulphur—·071 per cent.—to some degree. As regards "cold shortness," which another witness mentioned, it may be accounted for by the excess of phosphorus—·11 per cent. It was stated by Mr. Smith-Casson that the analysis was made from a fire box plate, and he further remarked that he "would never put basic Bessemer steel plates into boilers." This statement should give serious concern to makers of basic Bessemer steel, and we hope that persistent efforts will be made to bring about improvements in its manufacture, and corresponding improvements in its uniformity, and in that way increase the confidence of steel users generally.

Letters to the Editor.

THE COST OF CENTRAL STATION LIGHTING.

To the Editor of "Industries."

Sir,—In making a few remarks on Mr. Crompton's article in your last issue, I should like to premise that I do so without any feelings of enmity to the secondary battery. It has been immensely improved lately, and is still improving, and I should not be in the least surprised to find positive plates put in this year still working well in 1891, or even '92; further, I should consider any isolated installation incomplete without a storage battery. When it comes to central station working, however, I cannot help thinking that they must give way to the A.T. system, to use Mr. Crompton's notation. The figures for engines, dynamos, and buildings I will not presume to criticise, as Mr. Crompton knows a great deal more on the subject than I do. As to the cost for mains, however, his figures seem rather open to question. Does he really maintain that the respective cost of distributing mains at 2000 volts and at 100 volts is only in the proportion of 16 to 14? For the alternating leads it is proposed to lay a conductor to carry 40 ampères. To have the equivalent on the B.T. system at 100 volts means a conductor to carry 800 ampères, instead of which only one of ½ sq. in. section is allowed for in the estimate. The difference in cost of charging mains is much fairer, and probably nearer the mark, though rather favourable to the B.T.

When we come to the transformers themselves, I must confess I am unable to follow Mr. Crompton. What grounds has he for saying that 150 transformers are much too few for 10,000 lights? In his estimate he has: "Transformers, one large one for two houses; three hundred at £25, including fixing, £75,000. This being for 1450 h.p., is only 5 h.p. per transformer, which, so far from being a large size, is a fairly small one. If the houses in the district are all so small as to require a maximum of only twenty-five lamps each, one transformer would be quite enough for each group of four houses, and a 10 h.p. transformer would not occupy more room than an ordinary gas meter." Besides this, Mr. Crompton assumes that all the houses are small, whereas in the paper he is criticising the estimate of 150 is based on houses of different size, some of several hundred lights to make up for the very small ones. In conclusion, I may say that, in common no doubt with many others, I am looking forward with great interest to the paper which Mr. Crompton has promised on the subject at the Society of Arts and at the Society of Telegraph Engineers.

Yours, &c.,
London, 20th March, 1888. C. W. S. Crawley.

To the Editor of "Industries."

Sir,—I have read with much interest the article by Mr. Crompton upon the above subject, in which he criticises the statements and estimates made by the writer of the article which appeared in your issue of 2nd December, 1887. Mr. Crompton, in comparing the relative costs of two similar undertakings carried out upon the different systems of electrical distribution, called by him the B.T. and the A.T., or battery transformer and alternating transformer method respectively, has endeavoured to show that with regard to first cost the two systems are practically identical; and if I were to admit this, I would like to ask him whether he considers the cost of *maintenance* would be also identical—that is to say, whether he can keep storage cells in order for the same sum as will be sufficient to allow for depreciation upon the transformers employed. I do not believe he would make that assertion. In glancing over his estimate upon the A.T. system, I notice he has allowed £7,500 for transformers. Considering that the maximum output is to be 10,000 lamps of 60 watts each, and allowing for 5 per cent. loss in conversion (an excessive amount), the total e.h.p. required in transformers will not exceed 900, and this at his figure gives about £8. 6s. 8d. as the cost of transformers for each e.h.p. Now, this is altogether wrong. Taking it all round, the Gaulard-Gibbs transformers, as now made, do not cost more than £3 per e.h.p., and the sum therefore that would be expended on this item would not exceed £2,700. This alone makes a reduction of £4,800 in his estimate. There are many other figures in the article that require amendment, and, if you will allow me, I will try to deal fully with the matter next week, not having yet had leisure to go into the necessary calculations.

As regards the intrinsic merits of the two schemes, I grant that the possibility of storage gives an advantage to the B.T. system; but I contend that, though that method of distribution looks very pretty and appears very feasible *on paper*, yet as a commercial undertaking, and one calculated to compete successfully with gas for large towns, it is not to be compared with the transformer system employing alternating currents.

The result of the last two years has been to show that the system which will meet public and domestic requirements, that will break down existing gas monopolies, that will go right ahead in the teeth of opposition, that will be reliable, effective, easily understood, cheap to erect, and inexpensive to work and maintain, is the system that will be adopted in towns both large and small. How is it that, in the United States, the battery transformer system, though ably promoted and exploited, has made no way, whilst the comparatively new method of electrical distribution by alternating current transformers, beautiful in theory, and beautifully simple in actual working, has carried everything before it? The answer is not far to seek.

Yours, &c.,
J. Kenneth D. Mackenzie.
London, 20th March, 1888.

UNDERGROUND ELECTRIC LIGHT WIRES.

To the Editor of "Industries."

Sir,—In your article on underground electric light wires of last week, you refer to work carried out in America, where lead covered cables seem to have produced the best results and given least trouble. I desire to call your attention to the work in Philadelphia under the direction of Mr. D. R. Walker, the superintendent of the electrical department of that city. I had an opportunity of seeing this work in detail last year, and reference has been made to it at the recent convention in Pittsburg. The lead covered cables there referred to are the "Waring cables," and one important example of the success of these cables is the following: A three-wire clover leaf anti-induction cable, 1500ft. long, was placed in a conduit, and on the two outer wires the alternating current was put, working a 20-light converter placed in the chief's office. This telephone was connected with the third wire, and there was not a trace of interference on it when the alternating current was on. The wires in this cable are each separated by lead. This experiment disposes of the argument of the Brooklyn Commission, who say that electric light and telephone circuits cannot be worked side by side. The Long Distance Telephone Company, operating between New York and Philadelphia, are using three miles of this same cable as terminal sections to their line, and generally these cables are used to prevent induction where there is a large number of electrical currents near, or, as in the case above referred to, where different currents are used in the same cable. At such an important time as this, when a reliable underground conductor is being looked for, I think you will consider it only fair that the name of the "cables" referred to should be made known to the public.

Yours, &c.,
Frank Brewer, Assoc.M.Inst.C.E.
London, 20th March, 1888.

ALLOYS AND THEIR PROPERTIES.

In our last week's issue we gave an abstract of Professor Roberts-Austen's first lecture on this subject before the Society of Arts, and we now give an abstract of his second lecture. The lecturer began by dealing with the evidence afforded by the passage of an electric current through alloys. He took first the case of a molten alloy, and quoted the experiments of Obach and Haga, who had shown that when a current was passed through amalgams and through certain fusible alloys, there was no separation of the constituent metals. He then described his own experiments on alloys of lead and gold, and lead and silver, in which he employed an intense current of no less than 300 ampères. These experiments also showed that even with a very strong current there was no separation of the constituent metals, the experiments going far to show that molten alloys conduct like metals, and do not act electrolytically. Then arose the question: "Are there any metallic alloys or quasi-compounds of metals which can be in the slightest degree electrolysed by the passage of an exceedingly intense electric current?" He then dealt at some length with the experiments of Matthiessen on the electrical conductivity of solid alloys, the most interesting results of which he considered to be the evidence they afforded that the constituent metals of certain alloys could exist in allotropic states. He then proceeded to deal with the evidence as to the existence of metals in an unalloyed condition in allotropic forms, referring to the allotropic copper of Schützenberg and lead of Bolley, and turned to the evidence that in slow cooling gold and silver might be made to pass through allotropic states, illustrating his remarks more especially by reference to the beautiful experiments of Van Riemsdijk on super-fused gold and silver. The behaviour of these metals was compared with that of cooling sulphur, which, as Gernez has shown, may be made to crystallise in either the octahedral or the prismatic form, according to whether the germ which starts crystallisation belongs to the one or the other of these forms, and he referred to evidence of the same kind in the case of alloys of tin and antimony afforded by experiments by Jussien on alloys of lead and antimony. He then described the results of his own experiments, which formed the subject of a paper which he had read before the Royal Society on Thursday last. These experiments dealt with certain mechanical properties of metals considered in connection with Mendeléef's law of periodicity. He quoted numerous instances to show that the influence of "traces" of metallic and other impurity on metals was in some cases very extraordinary, and referring more especially to the case of gold, he gave evidence in favour of his conclusion that the influence exerted by the particular element on the tenacity and extensibility of metals bore a direct relation to the volume of the atom possessed by the added element—that the greater the atomic volume, the greater was the decrease in tensile strength. When this atomic volume of the impurity was less than that of gold, the tendency was for the tensile strength to increase. Evidence was given at much length to show that the influence of such impurities was directly under the control of Mendeléef's law. The lecturer stated that if his view as to the influence of the atom volume should prove to be correct, many obscure points in metallurgy would be satisfactorily explained.

Legal Proceedings.

The Snedshill Iron Company v. David Wood & Sons.

This case, which is of much interest to boiler makers and engineers, and worthy of the attention of steel makers generally, was heard on the 10th inst. at Shrewsbury Assizes, before Justice Smith, without a jury. The case arose out of a dispute about the quality of some basic Bessemer steel plates which the Snedshill Iron Company, Oakengates, supplied to Messrs. David Wood & Sons, boiler makers, Cradley Heath, Staffordshire, and for payment of which the Snedshill Company sued. It was shown that the defendants in November, 1886, obtained from the plaintiffs a set of plates for a boiler, which was in due course finished satisfactorily. For other boilers, the defendants then ordered in December further supplies of plates from the plaintiffs, stating that they were to be the same as last supplied, and "for high pressure boilers," at the same time stating on the order that certain plates with the letters "F. W." attached were for flanging and welding. These particular plates it appeared were for the cross tubes of vertical boilers; but when Messrs. Wood received them they found them unsuitable, inasmuch as they could not weld the steel nor flange it—the welds were imperfect, and the flanges tore open in turning down. In order, however, to finish the work they had in hand, they had to do their best towards making sound work in the tubes; but when the hydraulic tests were applied to the boilers they failed at the flanges and in the welds of the tubes in so much that the latter had to be removed and new ones put in. Meantime the defendants lodged a formal complaint respecting the steel for the tubes, and sent one of them to the plaintiffs to show the defects. The plaintiffs sent a representative to see the remainder at the defendants' works, and he admitted—according to the defendants' statement—the unsuitability of the steel for welding. The defendants wrote the plaintiffs intimating that they were returning the defective steel, but did not do so. All this occurred in the latter part of 1886 and beginning of 1887. Meantime, the plaintiffs had received no payment for any part of the steel which was supplied to the second order, and ultimately issued a writ against the defendants for the whole amount of the invoice, viz., £68. 14s. The defendants, considering themselves entitled to consequential damages, deducted £38 from the above amount for loss of material and workmanship, and for the loss sustained by removing the defective tubes, and paid the remainder (£30) into Court as sufficient to cover the plaintiff company's claim.

In opening the case for the plaintiffs, Mr. Spearman practically admitted the unsuitability of the plates supplied for the tubes, but submitted that no other claim of the defendants could be allowed. There had been no complaints about other plates until proceedings were taken. Mr. Jelf, acting for the defendants, advanced a counter claim for the losses above mentioned, and asked for damages sustained by the defendants in the loss of business by the sale of the boilers which had turned out defective in the tubes, and which had been seriously complained of by the purchasers. He also stated his intention to show by the analysis of the steel, and by the evidence of technical experts which he would call—viz., Mr. A. E. Tucker, of Smethwick; Mr. Thomas Turner, assistant manager of the Corngreaves Steel Works, Birmingham; and Mr. R. Smith-Casson, manager of Round Oak Works, Dudley—that many of the plates, other than tube plates, were unsuitable for boiler work, and that therefore the defendants were entitled to damages in respect of the dangerous position in which they were placed, viz., that of being called upon at any time within the next six years for damages which might be caused by the failure of any of the three boilers made from the plates supplied by the plaintiffs. His Lordship demurred to this latter claim, and said it was highly improbable that he could award any damages of that kind.

Mr. A. D. Ellis, general manager of the Snedshill Iron Company, was first called, and stated the facts concerning the orders and the correspondence. In cross-examination by Mr. Jelf he stated that some of the chief partners of the Snedshill Iron Company were also partners in the Lilleshall Iron Company, and that the Snedshill Iron Company purchase the whole of their steel, for rolling into plates, from the Lilleshall Company, who manufacture it by the Bessemer process. It was shown later in the proceedings, that the process carried on by the Lilleshall Company is not the ordinary Bessemer, but the basic Bessemer process. In his examination of Mr. Ellis, Mr. Jelf endeavoured to elicit from him an admission that the basic process was even yet on its trial as compared with the ordinary Siemens and Bessemer processes, that the results were very irregular and unreliable, and that much of the work done in steel making at Lilleshall had been experimental. To all of these inquiries Mr. Ellis replied with a direct negative, and as his Lordship interposed, and stated that any defects of the process, even if it had any, would not affect the question at

Digitized by Google

issue, as it was only necessary to adduce evidence respecting the particular plates in question. Mr. Jelf thereupon handed to Mr. Ellis an analysis of one of the plates as follows, viz.:—

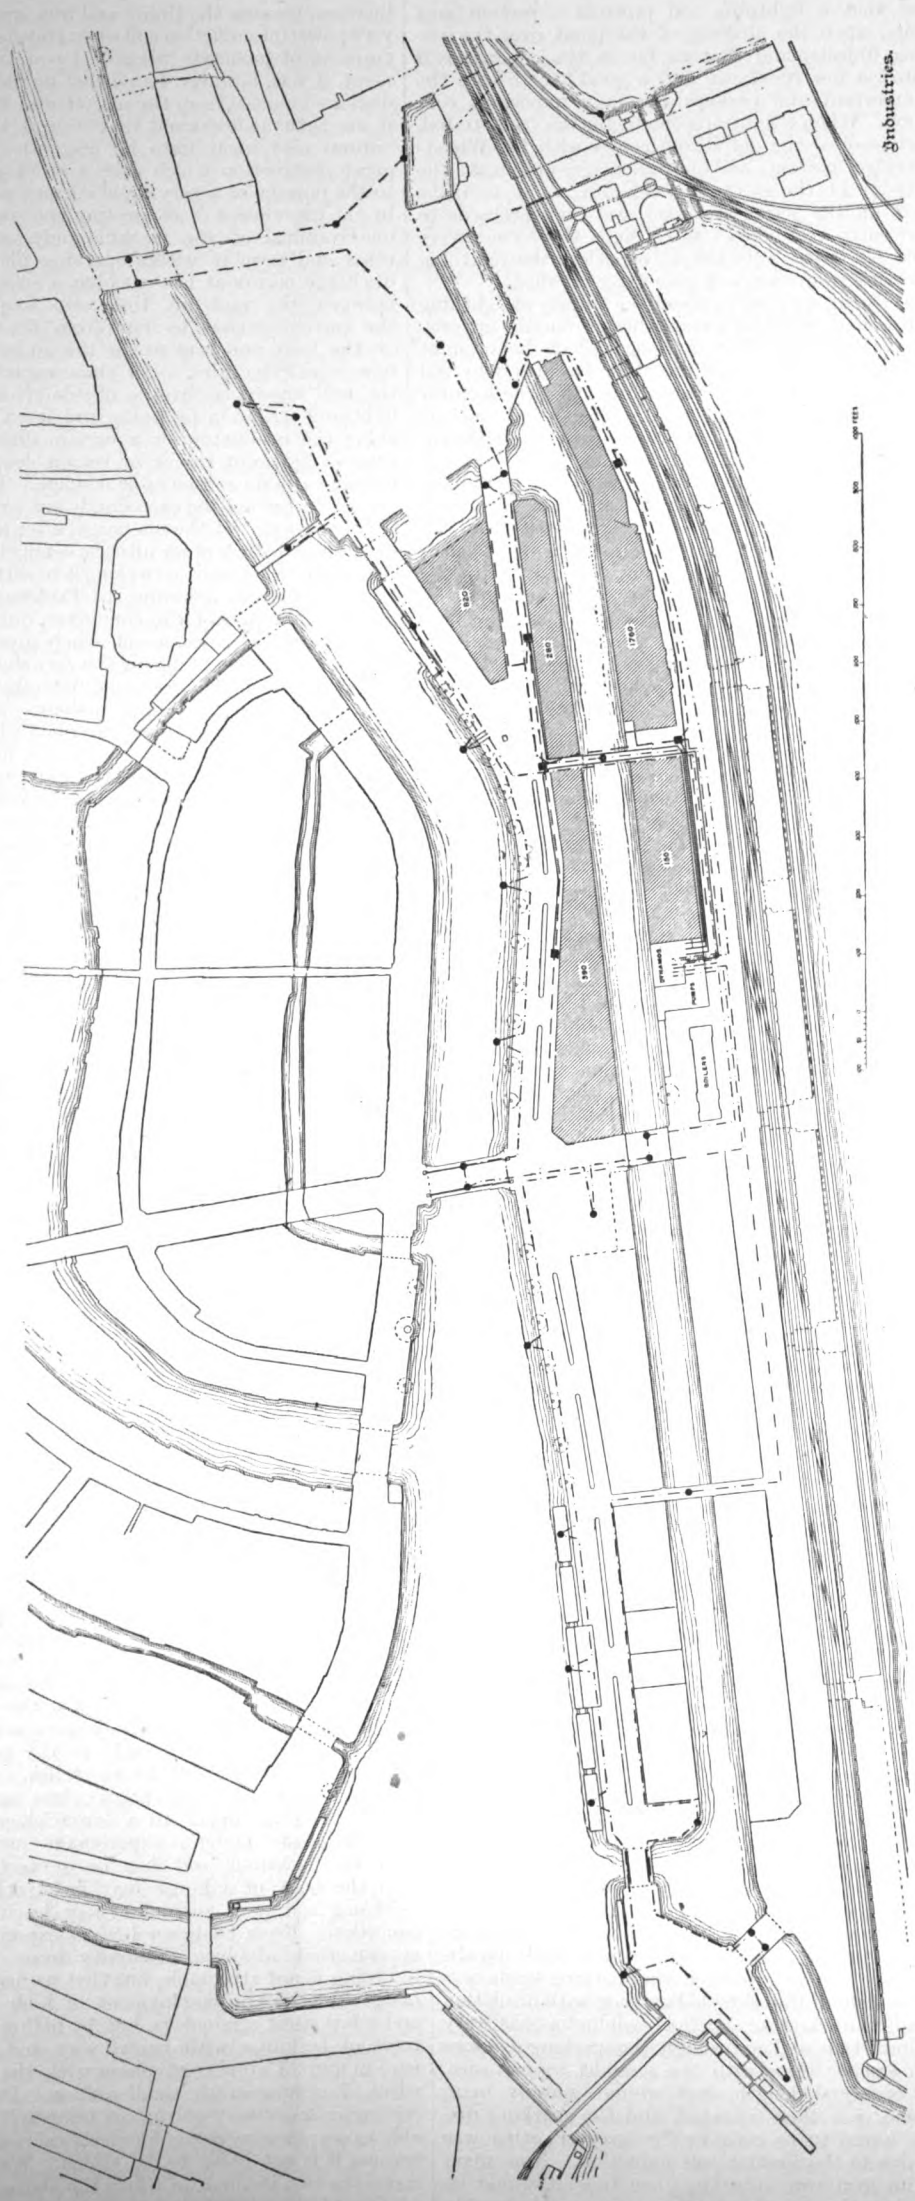
Carbon	·11 per cent.	
Silicon	Nil	
Phosphorus	·11 per cent.	
Sulphur	·071 „ „	
Manganese	·51 „ „	
Oxygen	·24 „ „	= ·8 per cent. oxide of iron

pointing out that it was not from a tube plate but from part of a fire box, and asked Mr. Ellis to give his opinion as to the suitability of such steel for boilers. Mr. Ellis, however, disputed the accuracy of the analysis, and stated that ·24 per cent. of oxygen could not co-exist in a steel made by the basic process with ·11 per cent. of phosphorus and ·51 per cent. of manganese. He further stated that if it had contained ·24 per cent. of oxygen they could never have rolled it, as it would have gone to pieces in the rolls. He considered it probable that the analyst had allowed some of the surface scale to get amongst the drillings—hence the apparent excess of oxygen.

Mr. W. H. Wood, a partner in the defendants' firm, detailed the matter of the correspondence, and the difficulties they met with in trying to weld and flange the steel cross tubes. He also stated that after completing the boilers they found them so unsatisfactory that they had to remove the cross tubes and replace them by new ones—costing in all about £20.

Mr. A. E. Tucker proved making the analysis above mentioned from a piece of steel in Court, and which Mr. R. Smith-Casson said was cut from a plate he procured in defendants' works. Mr. Tucker considered the steel would deteriorate rapidly, owing to its composition. He found it "red short," and thought that in parts where subject to the action of the fire its "life" would not be more than five years.—Mr. R. Smith-Casson stated that he had seen several plates, besides tube plates, in defendants' works, and all were defective in the same way. He had tested one of the plates, and found the steel "cold short." He considered it quite unsuitable for boilers, and under extreme heat would be dangerous. He would never put basic Bessemer steel plates into a boiler.—At this stage his Lordship suggested that this indirect evidence was unnecessary. There was no brand or mark on the piece of plate submitted to show that it was from any plate supplied by the defendants; besides, he did not see that he could admit any evidence regarding plates that had not been complained of before the action was commenced. The plates had been supplied in 1886, and the analysis and tests had been made in March, 1888. In the correspondence he could find no complaint of any plates except tube plates, and for these plates which were defective he would strike off £8. 12s. 6d. from the plaintiff company's claim, and would allow the counter claim of £20 for the cost of replacing the defective plates in the finished boilers. He could allow no claim of defendants for damages in respect of plates which had been worked up into boilers satisfactorily, no matter what doubt might be cast upon their quality by the analysis. Defendants having paid £30 into Court, the judgment was for £10. 1s. 6d., the defendants to receive costs on the counter claim.

THE PROTECTION OF BUILDINGS FROM LIGHTNING.



The commercial applications of dynamic electricity have of late years so engrossed the minds of scientists and engineers, that certain phenomena which we were in the habit of regarding as pertaining to static electricity have been somewhat neglected. The most important amongst these are undoubtedly those associated with atmospheric electricity. Private persons find it more profitable to concentrate their attention to the artificial production of electric currents and their use for commercial purposes than to the safety appliances to be provided if we would ward off the danger of an occasional electric current as supplied by the heavens, and thus the question of lightning rods and conductors and their best arrangement has been left to be dealt with by commissions and learned societies. Notwithstanding the labour of the Lightning Rod Commission some years ago, the principles which should guide the architect in devising lightning conductors are still only vaguely understood, and rival systems have apparently equal claims for adoption. The protection of buildings from lightning has not yet been developed into an exact science, and the opinions of experts on the subject differ as widely as ever. In Germany the Berlin Society of Electricians have from time to time formulated certain useful rules to be adopted in the arrangement of lightning protectors, and an experimental station has been established in Upper Silesia. As recently as the 4th of January last, the Berlin Society of Engineers discussed the question whether lightning conductors should or should not be connected with the water and gas mains. In a paper by Herr Oesten on the subject, it was stated that out of the 20,000 houses which in Berlin are connected with the water supply, the mains in fifteen or twenty houses are daily under repair, and may for such purpose be disconnected from the street mains. If then the water pipes are relied upon as the only earth connection, these fifteen or twenty houses would for the time be in an exceptionally dangerous position. It would thus appear necessary to provide either a separate earth connection, or to make the connection with the water mains so that it will not be interrupted by repairs in the house service. In these, as in all previous investigations of the subject, it has been assumed that a lightning rod protects a certain area depending upon the altitude of the point over the surrounding objects, and that as far as the conductor is concerned, a low resistance and a good "earth" are the most important and perhaps the only important consideration. When a lightning conductor has to be tested, the electrician of the old school comes with his Wheatstone bridge, battery, and galvanometer, and tests the conductivity of the rod and conductor, so as to make sure that all the joints are good, and then proceeds to test the earth resistance. If he finds the former very high and the latter very low, he considers the lightning protector in good order, and goes away satisfied.

These elementary notions about the efficacy of lightning conductors have received a rude shock from the investigations of Professor Oliver J. Lodge, which he brought before the Society of Arts in the Mann lectures delivered on the 10th and 17th of the present month. The lecturer wisely determined to discard all preconceived notions which are current regarding the nature of lightning strokes, and to start his investigations on a perfectly new experimental basis. In his experiments he did not use the method adopted by Franklin, who, as is well known, flew a kite and obtained electric sparks from the clouds; but he used a Voss induction machine and Leyden jars, by which means the element of danger in the experiments was obviated, whilst at the same time the phenomena were under better control. The arrangement of the apparatus may be thus briefly described: The terminals of the Voss machine were connected with the inner coatings of two Leyden jars standing upon the table, whilst their outer coatings were connected with two metal rods supported on glass stands. The ends of these rods, which terminated in knobs, could be approached more or less, and thus the sparking distance could be varied. The potential on the two outer coatings when the charge is slowly accumulating must evidently be equal; but when a spark occurs at the machine between its electrodes, the distribution of electricity is disturbed, and a second spark may occur between the sparking rods. If, now, these sparking rods should be joined by a stout copper wire of very low resistance, it would at first sight appear that no spark at all could be obtained, however near the knobs were placed. But, to the surprise of everybody who saw the experiment, the length of spark was scarcely diminished by joining to the knobs the ends of a No. 1 B.W.G. copper wire running round the room. We have then this extraordinary phenomenon, that although the two rods are in perfect metallic connection, the discharge prefers to take the short path through the air, which must have an enormous resistance, rather than the long path through the copper wire, which has practically no resistance. The explanation, as given by Professor Lodge, is that the self induction of the copper wire is so great as to almost entirely prevent the passage of a current within the very short time the spark lasts. A thin iron wire of equal length was then substituted for the copper wire, and although this had a considerably higher resistance, the sparking distance was not materially altered; it was, in fact, slightly less with the iron wire than with the copper wire. Now, according to preconceived notions, the copper wire should have offered a much easier path for the passage of the current than the iron wire. In fact, when Professor Hughes showed some years ago his classic experiment on the self induction of straight wires, the conclusion was generally drawn from that experiment that lightning conductors should not be made of iron, but always of copper, because a wire of the latter metal has very much less self induction. It is well known that an iron wire when traversed by a current becomes circularly magnetised, and thus its co-efficient of self induction is increased as compared with copper, which, being a non-magnetic metal, cannot become so magnetised. But these experiments were made with currents of a period which must be regarded as slow in comparison with the rapidity of a lightning discharge; hence the iron had time to become magnetised, and develop a counter electromotive force. In Professor Lodge's experiments it appears that the time of the discharge is too short to allow the iron wire to become magnetised, and its greater resistance would seem to constitute even an advantage in slightly diminishing the length and violence of the spark. To further elucidate this point the lecturer inserted a capillary tube of very high resistance (some 100,000 ohms) as a shunt between the sparking knobs, and it was found that the energy of the spark had much diminished. The influence of self induction was also shown by a subsequent experiment in which a shunt between the sparking knobs was formed by a strip of tinfoil folded zig-zag, with insulation between adjacent layers. Such a conductor has very little self induction, and accordingly the sparking distance was much smaller than with the straight copper wire. A tinfoil of equal length, but wound spirally upon a glass tube, was then inserted, and the sparking distance was found to be considerably greater; this was evidently due to the greater self induction. Now, upon inserting an iron core into the glass tube, it would be expected that the length of the spark would sensibly increase, because the tinfoil and iron core would act as a very powerful induction coil when traversed by alternating currents of moderate period. Upon trying the experiment, it was, however, found that no increase of sparking distance resulted from the insertion of the iron core, and it was thus made evident that iron at these rapid alternations completely loses its magnetic properties. The great obstruction which even a stout copper wire offers to the passage of a very rapid current was further shown by the experiment of connecting one end of the wire to one terminal of the machine only, and bringing the other end near it within sparking distance. When a discharge occurs at the machine, a spark is also formed between the ends of this wire loop, showing that the current prefers to flow from the nearer portions of the loop, and leap across the air space rather than flow round the wire. All these experiments illustrate the well known occurrence of side strokes. If a flash of lightning strikes a lightning rod it will sometimes run along the conductor for a certain distance, and then, without apparent rhyme or reason, leap across into the building and do considerable damage. The resistance of the conductor may be exceedingly low, and the earth may be very good; yet the discharge, after leaping through a few hundred yards of air into the conductor, does not take the path of least resistance along it to earth, but strikes off. The explanation, according to Professor Lodge, is that the self induction of the conductor, quite irrespective of its electrical resistance, is sufficiently great to prevent the passage of the current during the very short time of a flash, and thus forces the discharge laterally outwards. He illustrates this by hydraulic analogy. Suppose we have a tube bent into a U shape and filled with water. If on the surface of the water in one limb is laid a piston, and a gradual pressure is applied, the water will be forced out of the other limb without causing any sensible strain on the tube; but if the piston on the surface of the water be struck a violent blow with a hammer there is no time for the water to escape, although the tube may be very wide, and in that case the tube is liable to burst. The side flash from a lightning stroke corresponds to the bursting of the tube, and the evident remedy in the case of the tube is to make it of an elastic material; and in the case of the conductor, to give the system some elasticity of another kind, viz., more electrostatic capacity. This might, for instance, be done by connecting the conductor with one of the coatings of a Leyden jar; and on Saturday last Professor Lodge showed that by this means the sparking distance between the knobs could indeed be slightly diminished. The capacity of jar required for an actual lightning conductor would, however, be far too great to admit of such an arrangement in actual practice, and as a substitute the lecturer suggested that metal roofs and large conducting surfaces about the building should be connected with the conductor, so as to act as condensers. He also recommended to form the conducting system of a large number of thin wires in preference to the employment of a single thick wire.

The lecturer imitated the action of lightning by employing two metal plates fixed horizontally one above the other, but insulated from each other. The lower plate represents the earth, and the upper plate a cloud charged with atmospheric electricity. Into the intervening space are placed conductors terminating in metal knobs or points, and their upper ends can be set at various distances from the upper plate. Upon charging the upper plate from the machine a lightning stroke can be produced which will strike either one or the other of the objects placed between the plates, and by this means can be determined the liability which different objects have of being struck. When the charge slowly accumulates on the upper plate a point is struck sooner than a sphere, even if the point is further from the plate than the sphere; and between two spheres of unequal diameter a smaller sphere is more liable to be struck, although lower than the larger sphere. On the other hand, if the charge, instead of slowly accumulating, is suddenly transferred from another body to the upper plate, all objects are equally liable to be struck. Such a sudden transfer of the charge takes place when lightning strikes from an upper to a lower cloud, and in this case Professor Lodge's experiments make it evident that the lightning rod has no protective zone, and that the body of a house may be struck although its lightning rod and conductor may be in an excellent condition. From Professor Lodge's experiments it would appear that absolute immunity from the danger of lightning is not attainable, but that we may minimise the danger not by the employment of high lightning rods and a few stout conductors, but by fitting the eaves and roofs of buildings with barbed wire, and connecting the wire in a great number of places with the earth by iron wires of comparatively small section. Professor Lodge recommends ordinary galvanised telegraph wire as preferable to copper wire, partly for electrical reasons and partly because it is not liable to be stolen. We would recommend the two lectures, of which the above is only a short outline, to the careful attention of architects.

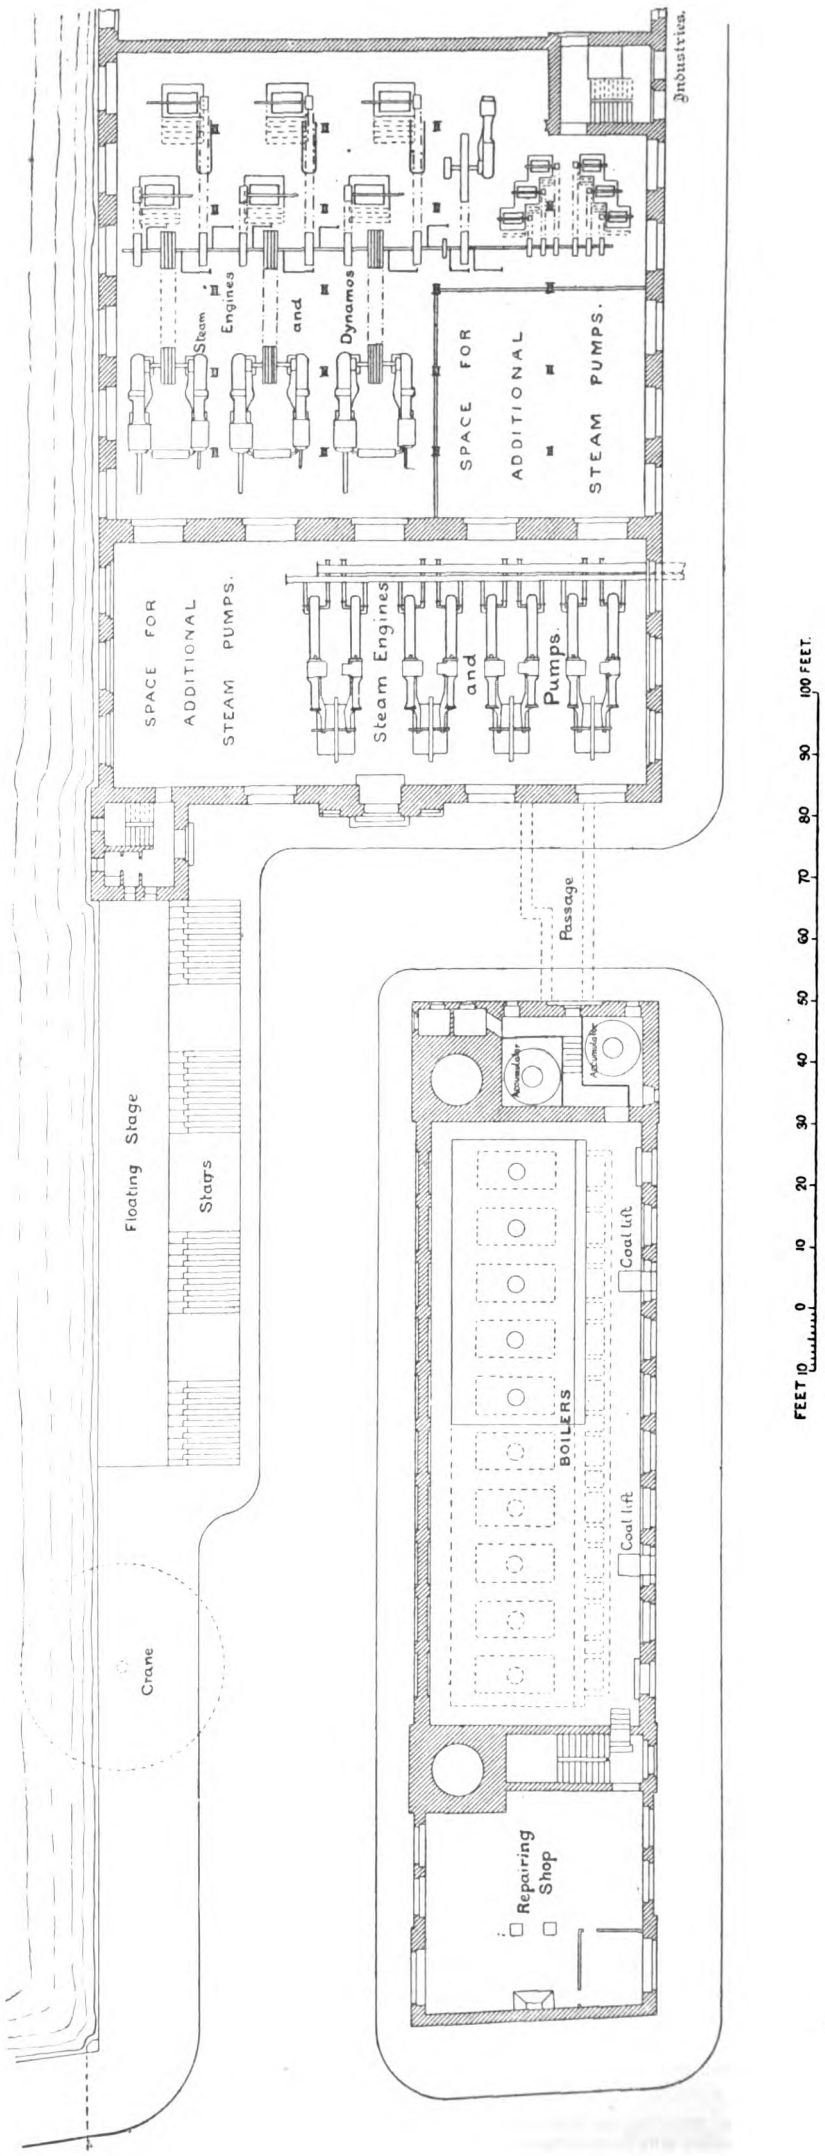
THE HYDRAULIC POWER AND ELECTRIC LIGHT INSTALLATIONS AT HAMBURG.

THE HYDRAULIC POWER AND ELECTRIC LIGHT INSTALLATIONS AT HAMBURG.

In May, 1881, the German Government came to an understanding with the State of Hamburg, according to which the latter agreed to join the German Customs' Union on or shortly after the 1st October, 1888. From this contract was excepted a small portion of the harbour within which the trade was to remain free, and it has been resolved to erect bonded warehouses on the quays of the free port, so as to give every possible facility to import and export operations. The whole undertaking, which is now on the eve of completion, was one of considerable magnitude, necessitating important changes in those portions of the town which lay near the new Customs boundary. About 440 sites had to be acquired either by private contract or under compulsory powers, and this expropriated not less than 16,000 inhabitants. The houses were pulled down to make room for roads and quays and for the bonded warehouses. The total cost up to the present amounts to about £5,500,000. The bonded warehouses, as all buildings in the neighbourhood of the river, are erected on pile foundations. The warehouses contain, in addition to cellar and ground floor accommodation, four upper floors and a floor below the roof. All the floors, with the exception of the two highest, have been constructed for a load of 3cwt. to the square foot. The total area which will eventually be covered by warehouses is 430,000 sq. ft. All the warehouses and the adjacent quays are supplied with hydraulic cranes, lifts, and winches; and the district is lighted throughout by arc lamps, whilst the interior of the warehouses is lighted by glow lamps. We publish on this page a sketch plan showing the position of the free port and bonded warehouses, those of the warehouses which are already completed being shown by hatched lines. The position of the arc lights is shown by dots, and the arc light circuits by broken lines. The figures in the space occupied by each building denote the number of glow lamps installed, and the black squares represent junction or distributing boxes for the glow light circuits. The plan on the next page shows the boiler, pump, and dynamo houses to a larger scale. The boiler house is a separate building, large enough to accommodate ten boilers, each of 1500 sq. ft. heating surface. Of these, five boilers made by the Hohenzollern works are now installed. The steam pressure is 100lb. per square inch. The coal is stored in a cellar under the street, and is hoisted by the lifts shown in the plan. At one end of the boiler house is a repairing shop, and at the other are two hydraulic accumulators for the pumps. In the engine house room is provided for eight pairs of direct acting steam pumps working at 50 atmospheres pressure. The pumps are automatically stopped and started by the accumulator striking tappets at the end of the stroke. The general arrangement of this hydraulic power plant is very similar to that of the London Hydraulic Power Company, which was taken as a pattern for the Hamburg installation. The total power of the hydraulic plant is sufficient to actuate 260 hoists, 50 lifts, and 36 cranes distributed along the quay walls. There is also some surplus power for working domestic hydraulic motors, if applications for this purpose should be received. At present there are erected only four pumps—of which one is spare—and two accumulators as already mentioned. Later on, when all the warehouses are erected and more power is required, the remaining pumps and a corresponding number of additional accumulators will be installed. The engines are horizontal compound, 18in. and 27½in. diameter of cylinder, by 27½in. stroke, working at sixty revolutions per minute. They are provided with surface condensers, the cooling water being taken from the river and circulated by a centrifugal pump. The piston rods are prolonged through the back cover of the cylinders and coupled direct to the pump plungers, which are differential, 4·85in. and 3·45in. diam. respectively. Above the engine room are placed two reservoirs containing together about 42,000 gallons, from whence the water is taken by the pumps. After passing through the mains to the various motors, the water is brought back to these reservoirs by a separate service of return mains. The accumulators have fixed cylinders and plungers of 24in. diam. The lift is 23ft., and the contents of each is about 450 gallons. The mains are throughout of cast iron, and the flanges are joined by india-rubber rings. There are at various places suitable branches and valves, so as to isolate any portion of the mains for repairs without interrupting the service over remaining parts. To avoid the bursting of mains from shocks there are fixed at several points short cylinders with plunger pistons held down by strong springs, and to detect leakage iron rods are fixed to the mains in various places, which come straight up to the street surface, so that the noise occasioned by the escape of water may be detected. The mains are laid sufficiently low to be out of the region of frost, and are embedded in sand and carried on brick work. The hoists in the warehouses are all adapted for a load of 12cwt. and a winding speed of 5ft. per second; whilst the lifts are arranged for a load

Digitized by Google



of 24cwt. and a winding speed of 3ft. 4in. per second. Most of the cranes along the quays are for 30cwt., but some for 5 tons are projected.

The electric light installation, when completed, will consist of fifty 10 ampère arc lamps, and about four thousand 16 c.p. glow lamps. The arc lamps are grouped in series of ten, each circuit being supplied by a separate arc light dynamo. The glow lamps are placed in parallel, and sub-divided into various groups, all fed from a main distributing switch board in the dynamo room. Power for the glow lamp installation is supplied by three pairs of compound engines of 220 i.h.p. each. Two of these engines are fixed. The high pressure cylinder is 15¾in. diam. by 31½in. stroke, whilst the low pressure cylinder is 23⅝in. diam. by the same stroke, the speed being one hundred revolutions per minute. These engines are provided with automatic expansion and surface condensers. The six arc light dynamos (five in use and one to spare) will be driven by a single cylinder non-condensing engine with 14¼in. cylinder by 28½in. stroke, running at ninety revolutions a minute. The cables are carried underground in rectangular iron troughs. The engines and dynamos are on the ground floor, and the dynamos are driven by belting from a main counter shaft fixed in the cellar, the latter receiving motion from the engines by rope gear. The pulley of each dynamo is provided on the counter shaft with a friction clutch, so that it may be stopped or started without interfering with the working of the other dynamos. For the glow lamp service there will eventually be provided six dynamos, but only four are now installed. These are eight-pole Schückert disc machines running at 350 revolutions, and designed to give a maximum current of 400 ampères at 120 volts pressure. The machines are all coupled in parallel by means of two main bars on the distributing switch board. There is an ammeter in the circuit of every dynamo, and an ammeter in every external circuit, of which eight are now fixed. The pressure is controlled by an automatic regulator, which we shall presently describe, and pilot lamps attached to small return wires inserted into each main cable are also provided as a guide for the attendant. The mains have been designed for a loss of pressure equal to 14 volts. In coupling the machines the exciting current of each is first regulated by a rheostat worked by hand, so as to obtain the same terminal pressure on all the machines. The rheostats are then coupled together, so that any further adjustment of the terminal pressure may be made simultaneously for all the machines. The pressure is, at the lamps, regulated by inserting more or less resistance into each outgoing main. This is done automatically by a relay electromagnet and rheostat to each main. The rheostat switch is an insulated barrel with circular metal contact fins of unequal length, which, when the barrel is slowly revolved, come automatically into action, inserting a greater or lesser number of German silver resistance coils into the main circuit. Each rheostat consists of fifteen German silver resistance coils. The switch barrel is revolved either in one or the other direction by means of ratchet wheels and pawls, the latter being continuously kept oscillating by a shaft which receives motion from the main shaft in the cellar. Each relay magnet is coupled to the return wires already mentioned, so that the attraction on its core is an exact measure of the pressure existing at the points of consumption. The core is suspended from an adjustable spring, and provided at its lower end with a metal stud playing between two contacts, so that a current may be sent through either one or other of two magnets controlling the two pawls. If the pressure is too high, the core rises and a current passes through the magnet which actuates that pawl by means of which the switch barrel is revolved in such a direction as to reduce the number of resistance coils in the circuit. If the pressure is too low, the core of the relay magnet drops and sends a current through the other magnet actuating the second pawl, which causes the switch barrel to revolve in the opposite direction and couple a greater number of resistance coils in parallel. In addition to the ammeters, there is provided a corresponding number of voltmeters, and the total quantity of electricity is measured by Aron's coulomb meters, one being provided for each dynamo and each circuit.

MINING IN ITALY.

The Italian Government intend disposing of the mine of Valle Imperina, near Agordo, which is owned by them, and which produces zinc, iron, copper, sulphur, and arsenic; and the Italian Consul-General informs the Board of Trade that his Government is prepared to give every inducement to the mine becoming a private undertaking. A report on the mine states that its importance is likely to be greatly increased by the extension of the railway from Treviso to Belluno, and by improvements in the processes used for extracting the minerals from the ore. It is also suggested that material at present wasted might be used for the manufacture of sulphuric acid.

THE HYDRAULIC POWER AND ELECTRIC LIGHT INSTALLATIONS AT HAMBURG.

THE PHYSICAL SOCIETY.

At the meeting of this Society on the 10th. inst., Mr. G. L. Addenbrooke read a paper describing a new portable reflecting galvanometer and a lamp of more convenient construction than those hitherto used for these instruments. The galvanometer had been designed to meet the requirements of electric light and telephone engineers. It is mounted on an ordinary ebonite stand with levelling screws, and the coils are removable, so that coils of different resistances can be used. The suspending fibre is wound upon a spindle, which can be removed from the instrument when it has to be carried, and a damper is attached to the mirror. The instrument exhibited was a single needle one; but astatic galvanometers can be made on the same principle. The adjusting magnet slides without turning on an upright rod attached to the cover of the case; and when it has to be turned, this is done by turning the upper part of the case, which is graduated, so that it can always be replaced at once in the position required. The lamp is smaller than those generally used, and is contained within a brass cylinder. It can be raised or lowered to the extent of about 6in. The lens is movable about a centre coinciding with the centre of the wick for adjusting the beam of light, and the wick is kept in the right position by passing the brass spindle, by which it is raised or lowered, through a slot in the case. The lamp is filled by a funnel without removing it from the case. Mr. E. C. Rimington then read a paper on

The Measurement of the Power supplied to the Primary Coil of a Transformer.

The subject was suggested by some observations made by Professor Ayrton in the discussion on the paper recently read by Mr. Kapp at the Society of Telegraph Engineers, in which Professor Ayrton described his method of measuring the power by means of an electrometer. The author had devised a method which he regarded as an improvement upon Professor Ayrton's, as the latter requires two observations, while his only requires one. As in Professor Ayrton's method, he places a non-inductive resistance R in series with the primary coil; but instead of using an electrometer, he uses a high resistance Siemens dynamometer, the coils of which are respectively connected with the primary of the transformer and the non-inductive resistance. If $\frac{K}{R}$ is the constant by which the dynamometer reading must be multiplied to give the power when continuous currents are employed, the power with the alternating current is

$$P=\frac{K}{R}\left(1+\tan^2\psi\right).\delta$$

The angle of lag ψ is a quantity which must be determined from the periodic time and other known conditions of the apparatus.

Professor Ayrton pointed out that the method was identical in principle with the one described by him, and open to the same objection of requiring the introduction of resistance into the primary circuit; but was distinctly inferior to it, as it requires the period of alternation to be known. He considered that a method was greatly wanted of measuring the power supplied to a transformer without introducing a resistance, and not involving a knowledge of the period of alternation.—Mr. T. H. Blakesley stated that he had devised such a method, requiring only readings on two low resistance dynamometers, and that by the use of a third dynamometer the loss of power due to hysteresis could be determined. His method of reasoning was geometrical. In answer to a question by Professor Ayrton, he stated that he proceeds on the assumption of magnetic lag, but does not assume the existence of a constant co-efficient of self induction.

Professor Perry then read an abstract of a paper by Professor Ayrton and himself

On the Magnetic Circuit in Dynamo Machines.

The authors have worked out a number of formulæ for dynamo machines, involving not the actual numbers of coils on the armature, but the thickness t of the winding and α the highest permanent current in ampères per square centimetre of cross section in that winding. One of these formulæ is

$$W=\frac{2\,v\,N\,t\,\alpha}{10^9}$$

where W = Highest permanent power or output developed in watts;

v = Circumferential velocity in centimetres per second;

N = Total highest permanent magnetic induction through armature in C.G.S. measure.

Then, as the armature winding is thin $t\alpha^2=q^2$ a constant. In some armatures which are always very cool, q is 150, but it is usually 288 in the best modern machines, being much over 300 in some machines. q is less for finer wires. The output can now be expressed in various useful ways, one being

$$W=\frac{2q}{10^9}v\,N\sqrt{t}, \text{ whilst}$$

$$N=\frac{\frac{4\pi}{10}s^1A^1}{\frac{2(d+t)}{a_2}+\Sigma\frac{l\nu}{a\mu}}$$

s^1A^1 being ampère turns on one magnetic field magnet circuit;

d the clearance between armature winding and pole piece;

a_2 area of pole piece exposed to the armature [increased by a fringe all round of breadth $0{\cdot}8\,(d+t)$];

a the cross section of any part of the magnetic circuit of length l, through which there is an induction νN, the magnetic permeability being μ.

From this it follows that W, the permanent output, is a maximum when

$$\frac{2t}{a_2}=\frac{2d}{a_2}+\Sigma\frac{l\nu}{a\mu} \quad \ldots\ldots\ldots\ldots\ldots\ldots(1)$$

That is, when the magnetic resistance of the space occupied by winding on the armature is equal to all the other magnetic resistance of the circuit.

The value of this rule is very great. Thus, for example, we have

$$W^1=\frac{2\pi q}{10^9}\frac{v a_2}{\sqrt{t}}s^1A^1$$

The authors, after giving the history of the Fröhlich and other formulæ for the law connecting N and s^1A^1, that is, "the characteristic of the dynamo," said that they had wasted much time in trying to get a simple formula whose constants could be calculated from the sizes of parts of a machine. They pointed out, while giving credit to the Drs. Hopkinson for their valuable study of the dynamo, that even they were not able to calculate the characteristic for an existing dynamo with what can be called accuracy, and that for all practical purposes the following rule, which is based on (1), is accurate enough:—

1st. For values of N equal to about half the maximum value, it is only necessary to study the air resistance, and

$$N=\frac{4\pi}{10}s^1A^1\div\frac{2(d+t)}{a_2}$$

Let the straight line indicated by this be drawn upon squared paper.

2nd. For the maximum permanent value of N ($=a_1\beta_1$, where a_1 is the diametral section of iron in the armature, and β_1 is from 17,000 to 18,000 in good machines) find the value of s^1A^1 from the formula

$$N=\frac{4\pi}{10}s^1A^1\div\frac{4t}{a_2}$$

and plot these values of N and s^1A^1 as the co-ordinates of a point on the squared paper. Any person who has drawn characteristics of dynamo machines will be able to draw a curve through this point, touching the straight line, which will not differ materially from the characteristic of the constructed machine. In testing this rule on the "Manchester" dynamo, the authors were afraid to trust to their judgment, as the real characteristic was already known. They therefore assumed that a curve

$$N=p\tan^{-1}(k\cdot s^1A^1)$$

was tangential to the straight line, and passed through the point, and the result was shown, with the curves calculated by Dr. Hopkinson and the observations on the same sheet of paper. They stated that in the best modern machines for incandescent lighting the only place in which "throttling" of the induction was allowable was the armature; but the usual rule now was to have β constant everywhere—that is, no throttling anywhere.

THE MANUFACTURE OF SORGHUM SUGAR.

A recent report on the manufacture of sugar from sorghum in the State of Kansas, presented by the English Consul at Chicago to the Foreign Office last month, draws attention to the success which has attended the experiments of last year, and which seem to indicate that sorghum sugar making will become one of the most profitable industries of the country. The earlier attempts in America to introduce the sorgho or sugar grass did not show that the cultivation was sufficiently remunerative to enable the sugar obtained to compete with cane or beet sugar. The sorgho plant was introduced into the United States from China in 1855, and the African variety, or "imphy," was also tried about the same time; but the first crops were unsuccessful. In 1875, the cultivation had extended to several of the central States, and the quantity obtained in that year reached the total of 640,000lb., as compared with 20,000,000lb. of beet sugar, and 63,000,000lb. of cane sugar. From these first experiments, it was seen that the sorgho plant thrives best in localities which were too cold for the sugar cane and too warm for the sugar beet, and that the maximum yield of sugar was obtained if the plants were cut as soon as the colour began to change, immediately before the seeds ripened. It was also found that another essential element of success consisted in the immediate crushing of the cut stalks, as on standing the cane sugar present in the juice reverts to glucose. The defecation can be effected by heating the juice to a temperature of 70° to 80°, then adding lime, and finally evaporating the clear liquid. From 100lb. of stalk about 63lb. of sap can be pressed, which contains about 12½ per cent. of crystallisable sugar and 3·7 per cent. of molasses. The raw sugar from different localities has been subjected to analysis, and was found to contain some 92 per cent. of cane sugar and 2½ per cent. of glucose. The first sorghum factory was erected in Illinois in 1881, and in Kansas during the following year three more factories were opened. The yield of juice by the processes used in these factories was not more than 40 per cent. of the total juice present in the stalk, and those interested in the success of the new industry, by the aid of an appropriation vote from Congress, next tried the process of diffusion in the place of the heavy crushing which had proved so inefficient. Results obtained by the Franklin Sugar Company in Kansas showed that this method extracted all the sugar from the stalk; but, although assisted by the State, the company was unable to make the process a commercial success. On the advice of Dr. Wiley, the Chemist to the State Agricultural Department, Congress voted, in 1885, a fresh grant to the Parkinson Sugar Company at Fort Scott, in Kansas, and the experiments for the year showed that the success of the method would only be a matter of time. In 1886 the experiments were continued by the Agricultural Department, under the direction of Professor Swenson, and the suggestions made by him enabled the Parkinson Factory last year to attain a very favourable result on their year's work. The State Legislature has also recently passed an Act to encourage the industry, by allowing a bounty of 2 cents per pound for five years on all sugar manufactured in Kansas. The value of the sorghum sugar manufactured in Kansas last year amounted to upwards of 34,000 dollars, and the working expenses to 21,000 dollars, showing a considerable profit on the year's work, even when the bounty is not included in the figures. The factory at Fort Scott has plant capable of dealing with 170 tons of stalk per day, which is delivered at the factory by the farmers who grow it. The topped stalk is cut into small pieces by a feed or ensilage cutter, which removes the leaves and sheaths. The material is then carried to the upper part of the building by an elevator. The leaves and sheaths are blown away from the cut stalk by a series of fans, and the cleaned stalk is then cut into chips before being placed in the diffusion battery. Each tank of the battery is capable of holding one ton of chips, from which the sugar is diffused out by soaking in hot water. The water, which is heated by steam pipes, circulates through the series of tanks, and gradually becomes charged with the sugar, and the juice obtained in this manner is then drawn off to the defecating pans. Carbonate of lime is added to each tank to neutralise any acids which may be present, thus preventing inversion from taking place. Lime water is also added to the juice in the defecating pans, in order to insure neutrality before evaporation. After being heated and skimmed the juice is boiled to a syrup in vacuum pans, and is then removed to the "strike pan," a large air tight iron vessel in which the boiling is continued until sufficient water has been evaporated to insure the sugar crystallising out from the molasses in the centrifugal machines. The yield obtained at Fort Scott from one ton of sorghum last year was about 100lb. of sugar and 12 gallons of molasses. At present, no satisfactory process has been devised for obtaining the glucose in a marketable form, although this exists in the plant in considerable quantity, and is formed by inversion in the processes of manufacture unless great care be taken in the different processes. Dr. Wiley hopes to be able to preserve the stalk in silos after cutting without loss of sugar, which will allow of the factory working for a longer period, and enable the farmers to store their stalk until the winter season, and deliver to the factory at their leisure. In the report to which we have alluded it is calculated that the farmer should make £4 per acre for his crop, or about twice the yield of a crop of wheat, and the seed is of equal value to corn for feeding purposes. In France, where the sorghum plant is also now largely cultivated, especially in the districts of Vancluse and Le Gard, the grain, which contains about 40 per cent. of starch, is fermented, and by using diastase instead of acids, the residue is made available as a food for cattle. By the use of Champonnois' apparatus, good brandy can be prepared from the alcoholic liquid obtained by the fermentation of the grain. In France the cultivation has been found less costly than that of the sugar beet, and the yield of molasses is considerably less. In Hungary, within the last

Digitized by Google

few years, satisfactory crops of sorghum have also been raised, and the seeds have been used as a substitute for barley. In Pomerania, crops have been grown and used as green fodder for cattle. A recent report on "the sugar outlook," states that the production of sugar in the United States is less than the demand. Considerable quantities are imported to the Western States from the Hawaiian Islands, so that there seems to be a good opening for the new industry in the United States. In California, the manufacture of sugar from beet root is making rapid strides, and large factories are now in process of erection in the neighbourhood of San Francisco to deal with the crops which are there being raised. Sorghum can be grown in the zone north of the sugar cane producing States, and south of those where the beet root is found to thrive; and now that the experimental stage has been passed, the central States will have a sugar industry of their own, which bids fair to become a formidable rival to that of the other States.

Notes.

THE TRADE OF TRIPOLI.

A VERY unfavourable account is given by Consul-General Drummond-Hay of the state of trade in Tripoli, it being stated that there is no capital in the country, as owing to the depressed state of the ostrich feather market traders will not purchase feathers in the interior. British cotton goods are no longer sent in the same quantities as before to Bourun and Waday. A large decrease has consequently taken place in the imports of cotton goods, the value of British cloth manufactures imported in 1887 being £37,500, as against £53,000 in the previous year.

THE INDUSTRIES OF BALTIMORE.

LOCAL industry, says the British Consul at Baltimore, in a report to the Foreign Office, shows remarkable progress. The Pennsylvania steel works have purchased a thousand acres of land, with water frontage, near the city, and have commenced work with a plant which it is intended to extend until eight furnaces, with a daily output of 2000 tons of pig iron, and a steel rail mill to turn out 1000 tons of rails per day, besides other branches, are in operation. It is also proposed to establish a steel shipbuilding yard. Among other important industries carried on in Baltimore are railway carriage and tram car works, and food tinning factories. As regards the imports, it is mentioned that the receipts of chemicals, which come almost exclusively from England, show a slight increase.

BRAZILIAN IMPORTS.

THE increase of imports into Rio de Janeiro for the last official year amounts to about 2½ per cent., the advance being most noticeable in machinery, cottons, woollens, and silk. In cottons, the finer qualities show the most improvement, grey and white half bleached stuffs having declined. Hessians and Osnaburghs have fallen off. Coal, iron, and steel also show a decrease. There has been an augmentation in the value of the imports from England, France, Germany, Belgium, the United States, and Portugal; but German trade has advanced in a greater ratio than that of any other country, a fact which we would recommend to the notice of Mr. R. Giffen, who seems to be under the impression that we are holding our own against Germany.

ROUMANIAN IMPORTS.

THE negotiations between Roumania and Austria-Hungary for the conclusion of a commercial convention, to take the place of that which expired on the 1st June, 1886, have made but little progress hitherto, so that the general tariff continues to be applied to the greater part of the goods imported. On the other hand, an additional treaty of commerce has been concluded with Germany, which provides for several reductions in the tariff, by which, according to the British Consul at Galatz, British trade should profit. He also states that, so far as any judgment can be formed from the published statistics, which at present only give the gross returns of foreign trade up to the end of 1886, the commercial differences between Roumania and Austria-Hungary have benefited German imports more than those of any other country. The values given are: For Austria-Hungary imports in 1885, £4,827,000; in 1886, £3,740,000; Great Britain in 1885, £2,073,000; in 1886, £2,856,000; Germany in 1885, £1,660,000; in 1886, £2,933,000. German imports now rank as second in importance, the principal articles being woollen and cotton hosiery, haberdashery and knitted goods, woollen yarns, iron and steel rails, and metal goods. In metals, the proportion of German imports is very large, and this is no doubt due in some measure to reduced railway rates for through traffic between the two countries.

AGRICULTURAL MACHINERY IN RUSSIA.

IN an abstract of the report of the Russian Department of Agriculture, which has been sent to the Foreign Office, reference is made to the falling off in the imports of agricultural machinery. This is ascribed partly to the impoverishment of the landed proprietors and partly to bad harvests in those districts where expensive machinery, such as thrashing machines and reapers, is used. The trade is now limited to the purchase of cheap ploughs, harrows, and winnowing machines, and a few seed drills. The most popular with the peasantry is the one horse "Eagle" plough, and Swedish iron ploughs also meet with favour. Double and triple ploughs are being more extensively used, and those made by Messrs. Ransome, Sims, and Jefferies are highly spoken of. The imports of agricultural implements are likely to decrease further, as the duty was raised last November; the increased tariff does not, however, apply to machinery worked by a separate steam engine.

GAS BY INSTALMENTS.

WE have before alluded to the competition which gas companies suffer from petroleum oil. The preference of the poor for oil appears to be largely due to the fact that it can be purchased in small quantities—whereas the use of gas results in formidable quarterly bills. Several attempts have been made to meet small consumers in this matter; and the Corporation of Birmingham is now about to institute an entirely new departure in the sale of gas by the use of "pay-before-delivery" meters. A number of prepayment meters, constructed after the principle of the common automatic supply machines, have been offered by inventors; and a trial of one devised by Mr. Brownhills is to be made in a court of small houses. One or more pennies are dropped into an opening, and the regulating apparatus of the meter liberates a quantity of gas of corresponding value—after which it stops, awaiting the advent of fresh pence. The coins accumulate in a locked receptacle, and are removed by the collector at intervals. The mechanical arrangements of the meter will, it is believed, render fraud difficult; and they can be manufactured for about 20s. each.

GUN MAKING IN THE UNITED STATES.

THE *Scientific American* draws attention to the 6in. gun of cast steel now being manufactured at Pittsburg, by the Bessemer process, for the United States Government, and seems to take a very *couleur de rose* idea of this form of manufacture, stating that, as compared with the methods employed in Europe, casting will be more expeditious and cheaper; and if the gun be a success, a great advance will be made in the construction of ordnance. The gun has yet to be tested; but safety apart, it is, we believe, an undoubted fact that the cost of the gun when completed will not differ materially from that of the same calibre of forged steel lately constructed in the Navy Yard at Washington. Moreover, if one 6in. gun of cast steel be successful, it does not follow that those of larger calibre will be equally so. The difficulties in castings increase enormously with their weight; and in the case of the larger calibres, these weights will be excessive. The same journal also states that it is the opinion of American ordnance officers that the gun of the future will be of aluminium bronze, and that it will be lighter, stronger, and cheaper than the steel gun. The merits of this metal are that it is light—as light almost as glass—that it does not rust, is stronger than steel, and with suitable alloys, can be made to replace any other metal.

METALLIC MONEY.

IN the course of a paper read by Mr. J. B. Martin, at a recent meeting of the Institute of Bankers, on some recorded movements of coin and its equivalents during recent years, he stated that taking gold first, our knowledge as to the amount existing in this country, or in the world at large, is extremely vague. Examining the inquiry made by Professor Jevons in 1868, and comparing it with an inquiry conducted by himself in 1882, it appeared that Professor Jevons made what was probably a fair estimate at the time, but this method would not be equally applicable at present. The evidence points to the conclusion that in proportion as the gold coinage suffers from wear and tear, the best of the coins tend to disappear, and the worst to remain in circulation. The Bank of England returns from 1882 to the present time appear to show that about £1,315,000 have been added to the home circulation, while the returns of the registered imports and exports of gold show a balance in favour of this country of £3,420,000; but from a comparison of international statistics and other considerations, official statistics appear to be of very little value. As regards silver, there appears to have been in the years 1871 to 1886 an increase of more than £4,000,000, while there has also been an addition to the bronze coinage more than proportionate to the growth of population. The bank note circulation is steadily declining in every division of the country.

ELECTRIC LIGHTING IN THE UNITED STATES.

WE have already referred more than once to the enormous progress which is being made in the United States with electric lighting, as compared to what is being done in this country. The latest estimate on the subject of the American electric lighting industry is that given by Mr. J. F. Morrison, president of the National Electric Light Association, at their recent meeting in Pittsburg. He puts the present figures of electric lighting in the United States at 3000 incandescent and arc isolated plants, and 1000 central stations in which are installed or contracted for 175,000 arc lights and 1,750,000 incandescents. Mr. Morrison also drew attention to the difference in the growth at home and abroad, and said the whole explanation was to be found in vicious legislation.

DETECTION OF COLOURING MATTERS.

THE detection of colouring matters used in the adulteration of beer, wine, and other articles of food is rendered difficult by the presence of the natural colouring material of the substance, and chemists have hitherto been unable in many cases to certify to the presence of any particular colour adulterant for this reason. F. Goppelsroder has recently drawn attention to the researches of Schönbein on the separation of substances by capillary analysis, and has shown that by this method we have a very ready and simple means for separating and recognising individual colouring matters in their mixtures. If a strip of white unglazed paper be placed in a solution of several substances, the solvent rises more rapidly than the dissolved substances, and these have each their own rate of travelling. If colouring matters are present, zones of different colour are produced, and after some time the piece or pieces of paper can be removed and the substances on them extracted. The extract can then be treated in the same manner a second time, thus making the separation of the various colouring materials present still more complete. The separate zones will vary in their intensity and breadth with the amount of the several substances present, and the ordinary reactions can be applied to the materials on the paper when they have been thus separated. Mr. Goppelsroder has found this method to give very good results in examining food and various other articles to which colouring matters have been added. He has succeeded in detecting picric acid in beer, and fuchsine in wine, by its use.

STEAM VULCANISED FABRICS.

MESSRS. CHARLES MACINTOSH & Co., of Manchester, a short time ago patented an invention, for which it is claimed that it marks a new epoch in the history of the india-rubber manufacture. Notwithstanding the great advances which have been made in the other branches of this industry, very few important improvements have been effected in the manufacture of waterproof clothing. The trade, it is true, has been developed considerably by the employment of a greater variety of fabrics, and wool, silk, and cotton, alone and in combination, now form part of the stock of every dealer in waterproofs. The only obstacle to complete success has been that, hitherto, no manufacturer has been able to thoroughly "vulcanise" the rubber which is inserted between or spread upon the woven wool or silk. These fabrics being non-conductors of heat are not adapted to the ordinary process of steam vulcanising. Some waterproofers, however, have supplied so-called "steam vulcanised" goods; but with the appliances usually employed in this process, the cloth is necessarily dealt with in large rolls, and the heat which is required to thoroughly vulcanise the interior, would burn the outside folds almost to destruction, so that equal vulcanisation has not been accomplished. In consequence of this difficulty most firms have adopted what is known as the "cold cure" process, in which a mixture of bisulphide of carbon and chloride of sulphur is applied to the surface of the rubber. The effect of this is to harden or "cure" the outside surface of the rubber without penetrating far into the interior. The body of the rubber is thus left uncured, and is, in consequence, very liable to early decay. There is generally a most unpleasant smell attending the use of this liquor, and this fact alone is sufficient to condemn its use except on the ground that no practical substitute has been available. In the new process, the fabric is passed through a vulcanising chamber which is heated with air, and fitted in its interior with a system of rollers so arranged that the cloth, in its passage round them, shall occupy the necessary time to effect a complete vulcanisation. As the cloth is being continually wound off the feeding roller and on to another roller when vulcanised, no portion of it can receive more heat than another. The goods produced by this method will, it is said, remain soft and pliable when exposed to intense cold, and, what is of even more importance, they will not decay by being kept in stock in a hot climate.

Patent Record.

Compiled from "The Official Journal of the Patent Office," by W. E. Heys, *70, Market-street, Manchester.*

APPLICATIONS FOR PATENTS.

(The names in italics within parentheses are those of Communicators of Inventions.)

ENGINEERING.

9th March, 1888.

15878B. Popp, V. ..... Fluid meters. (This application having been originally included in No. 15878, dated 18th November, 1887, takes, under Patents Rule 23, that date.)
3621. Middleton, J. ..... Breech loading small arms.
3622-3. Rosson, C..... Ejector mechanism of breech loading small arms.
3630. Lockhart, J..... Axle guard for railway rolling stock.
3635. Wilmot, S. M. ..... Galvanised sheet iron roofing.
3638. Higham, J..... Knitting machines.
3640. Fielding, W..... Uncoupling railway trucks.
3649. Dickinson, W., & others Manufacture of paper.
3650. Haworth, J..... Self acting mules.
3651. Evans, P. ..... Governing steam engines.
3652. Stitt, J. C..... Steam engines.
3654. Jagger, E..... Placing cop tubes upon spindles.
3655. Ainsworth, W..... Paper bag making machines.
3656. Lund, E..... Pulsometers.
3659. Boult, A. J. ..... Sheet metal cylinders (*Wonson*).
3664. Bacon, D. H..... Wood turning machinery.
3665. Eades, W. S..... Machines for making "button pieces" for boots.
3667. Walker, H. A..... Wire twisting machine.
3681. Pugh, D..... Tube stoppers for boilers.

10th March, 1888.

3694. Holdsworth, C. ..... Winding yarn on to paper tubes.
3699. Dobson, B. A. ..... Bearings for carding engines.
3701. Fisher, J. A..... Gas engines.
3704. White, C. ..... Winding off yarn from bobbins.
3706. Stead, T. W..... Washing woven fabrics.
3711. Richardson, R..... Steam steering gear.
3712. Marks, G. C..... Machines for lifting heavy bodies.
3713. Norton, R..... Vertical steam boilers.
3715. Jefferies, J. R..... Vertical steam boilers.
3722. Muirhead, W..... Furnaces for the production of steel.
3723. Sutherland, M. ..... Indicating the water level in steam boilers.
3724. Norton & Wood ..... Looms for pile fabrics.
3730. Barthel, A. E..... Production of iron.
3745. McQuat, A. M..... Bottle washing machines.
3749. Willans, P. W..... Driving gear for screw propellers.
3751. Imray, O. ..... Fish plates for rails (*Lee*).
3752. Imray, O. ..... Construction of roadways (*Lee*).
3753. Harmel, A., & others ... Dyeing wool.
3756. Crossley, F. W. ..... Gas engines.
3762. Mosher, S. H., & others Feed water purifier.
3763. Brougher & Funk ..... Skinning knife attachment.
3765. Kingdon, G., & others.. Automatic direct action brake.

12th March, 1888.

3767. Whitworth, C. F..... Railway signals.
3770. Murray, R. ..... Copper castings.
3773. Wallace & Smillie..... Preventing corrosion of screw propellers.
3776. Arnell, J. C. ..... Extracting ferrules from the tubes of boilers.
3785. Winterflood, J..... Water heating apparatus.
3786. Worrall, T. D. ..... Type writing machines.
3789. Baker, G. W..... Leather staking machine.
3790. Herbert & Hubbard... Aiming of machine guns.
3799. Edmeston & Edmeston. Pistons.
3800. McNaught & McNaught..... Air pumps of steam engines.
3801. Selwig, J..... Rotary engine.
3804. Hainsworth, F..... Manufacturing wire fabric.
3806. Leslie, A. ..... Furnaces for smelting iron (*Massey*).
3807. Greenwood, H..... Manufacture of metallic cartridge cases.
3811. Effenberger, J..... Stretching apparatus for wool spinning.
3813. Sudheim, S..... Side couplings for railway rolling stock.
3817. Silverman, L. ..... Magazine fire arms.
3819. Thompson, W. P..... Spark arresters (*Jessl*).
3827. Longton, F. J..... Flour mills.
3829. Barclay, A. ..... Motor for direct acting pumps.

13th March, 1888.

3831. Bradley, E. ..... Wood slicing machine.
3837. Sleeper, F. H..... Lifting jacks.
3839. Jacobs, J. ..... Railway ties.
3840. Warner, H. G..... Prevention of priming in steam boilers.
3843. Wright & Ferdinand.. Cutting pile fabrics.
3847. Guthrie, H..... Gas engines.
3848. Jardine, J..... Machines for lace making.
3854. Ward, J. F..... Vessels' rams.
3857. Halfpenny & Halfpenny..... Annealing furnaces.
3858. Smith, H..... Metal fencing.
3859. Hall, J. W..... Machinery for cutting metal.
3863. Hannay & Doxford..... Burning liquid fuel in steam boiler furnaces.
3873. Crossland, J. E. ..... Keys in railway chairs.
3876. Henderson & Broadbent ..... Rotary engines.
3877. Willford, G. W..... Railway chairs.
3878. Whitehead, J..... Self acting mules.
3885. Cordingley, I..... Pulleys.
3886. Cooper, J..... Jacquards.
3887. Thompson, W. P..... Boats for saving life at sea (*Ducker*).
3892. Mewburn, J. C. ..... Metallic fencing (*Bère*).
3895. Brown, E. V..... Machinery for working leather.
3900. Jordan, T. R. ..... Apparatus for pulverising ores.
3901. Lake, H. H. ..... Vent plugs for steam radiators (*Waggoner*).
3906. Roberts, S. ..... Injector.
3907. Segschneider, G..... Looms for making cut pile fabrics.
3908. Essers, E..... Double pile fabrics.
3909. Wardle, W. W. ..... Rotary engine.
3910. Hoopes, C. R. ..... Liquid fuel in steam boiler furnaces.
3911. Kinnell & Rothnie..... Automatically regulating the supply of liquid fuel.
3913. Farmer, J..... Rolling round metal bars and tubes.
3914. Edwards, E..... Locomotives for ordinary roads (*Oury*).
3915. Appleby, C. ..... Heating feed water.
3918. Hamilton, H. ..... Apparatus for composing type (*Thorne Machine Co.*).

14th March, 1888.

3922. Tucker & Hatton ..... Manufacture of iron and steel.
3923. McMillan, T..... Ploughs.
3924. Jones, J. E. ..... Portable buildings.
3932. Paterson, D..... Ploughs.
3935. Farrar, J..... Twisting yarns.
3937. Heap, E..... Shaping metals to a cylindrical form.
3939. Matthews & Yates ..... Steam traps.
3946. Sharpe, A. H. B. ..... Tea rolling machines.
3953. Hitchon, A. ..... Mechanism for measuring woven fabrics.
3957. Gilmour, J. ..... Steam boilers.
3959. Owens & Butler..... Transmitting power to a distance.
3961. Mapplebeck, E. ..... Manufacture of twisted metallic tubes.
3963. Holland, W..... Tempering metallic wire.
3964. Gazé, E. H. ..... Gas engines.
3966. Hind, A..... Cut pile fabrics.
3972. Bellotti, S. ..... Grinding and polishing machines.
3973. Lewis, A. D. ..... Life saving boats.
3974. Oxley, T. ..... Flyers and spindles.
3977. Dunbar, A..... Manufacture of barrels.
3984. Gosling, R..... Consuming smoke.

15th March, 1888.

3993. Barry, J. H..... Revolving furnaces.
3997. Lovett, S..... Rotary traverse warp.
3999. Smith, D. ..... Punching & shearing machinery
4005. Ford & Clifford ..... Breech loading fire arms.
4009. Farrar, J..... Twisting yarns.
4011. Fletcher & Cawley ... Fire and burglar proof safes.
4014. Sharman, C..... Armour plates.
4015. Baker, J. M. B..... Removal of sand in rivers.
4018. Rothwell, J. W..... Grid for vertical cotton openers.
4021. Crompton & Cochran... Steam boilers.
4023. Eves, J. V..... Footsteps of spindles.
4027. Urry & Tasker ..... Hauling gear.
4035. Spear, M. H..... Printing machines.
4038. Alexander, A. E. ..... Polished sheet iron (*Craig*).
4042. Beaurain-Vautherin, C. Crucibles.

ELECTRICITY.

9th March, 1888.

15878. Popp, V. ..... Measuring the time during which a current of electricity is flowing. (This application having been originally included in No. 15878, dated 18th November, 1887, takes, under Patents Rule 23, that date.)
3670. Siemens, A. ..... Volt indicator.
3678. Olpherts, W. G..... Electrical signalling on railways.
3685. Sharp, S., & others ..... Electrical switches.

10th March, 1888.

3690. Dunn, E. ..... Railway electrical signalling apparatus.
3710. Tweeddale, J..... Electromagnetic motors.
3714. Cockburn & Day..... Electric fittings.
3740. Bernstein, A. ..... Cut-out and switch.
3766. Baldwin, G. J..... Collectors for dynamo-electric machines.

12th March, 1888.

3812. Berry & Franke..... Electrical glow lamps.

13th March, 1888.

3835. Copeland, H. P. ..... Telegraphic apparatus.
3841. Laurie, T..... Telephonic apparatus.
3883. Boult, A. J. ..... Electrical devices for type writers (*McLaughlin*).

14th March, 1888.

3921. Parker, T., & others ... Indicating, measuring, and controlling electrical currents.
3929. Parker, T., & others ... Dynamo-electric machines.
3968. King, J. W. ..... Regulation of arc lamps.
3981. Hopkinson, E. ..... Electrically propelled vehicles.
3986. Drake & Gorham ..... Secondary batteries.

15th March, 1888.

3995. Lake, H. H. ..... Galvanic batteries (*Walter*).
3998. Horsfield & Porter ... Electrical indicator for the locking apparatus connected with railway points
4008. Ullathorne & Gauzentes..... Electric batteries.
4017. Dorman, G. E. ..... Electric arc lamps

CHEMISTRY.

9th March, 1888.

3660. Howarth & Graham ... Calcination of cupreous ores.
3661. Browne, A. ..... Separating the tin from scrap.
3668. Clark, A. M. ..... Manufacturing soda and hydrochloric acid (*Daguin*).
3669. Clark, A. M. ..... Manufacture of sulphuric acid and hydrochloric acid (*Daguin*).

10th March, 1888.

3741. Appleby, C. ..... Ore concentrating machinery (*Rankin, Brayton, & Co.*)

12th March, 1888.

3793. Johnson, J. Y..... Metallic alloys (*Société Anonyme Le Ferro-Nickel*).
3802. Tack & Girard ..... Manufacture of coke.
3823. Butterfield, J. C..... Extraction of metals from ores.

13th March, 1888.

3880. Ellice-Clark & Chapman ..... Obtaining oxygen and nitrogen from air.

14th March, 1888.

3920. Thornton, J. ..... Coating iron with tin.
3926. Wolf, G. de..... Extracting gold from ores.
3949. Justice, P. M. ..... Hydrochlorate of quinine (*Weld*).
3965. Jordan, T. R. ..... Extraction of metals from ores.
3967. Brin, A. ..... Extraction of oxygen and nitrogen from the air.

15th March, 1888.

4034. Taylor & Struvé ..... Coating with tin, lead, or other metals.

MISCELLANEOUS.

9th March, 1888.

3624. Thompson, W. J..... Inside tappet for loom.
3632. Smith & Thomas..... Bobbin frame.
3636. Allen, A. H. ..... Filters.
3639. Rutherford & Fort... Washing barrels.
3662. Didier, J. L..... Cartridges.
3671. Halstead, C. ..... Coverings for rollers.
3673. Rowatt, J. M. ..... Lamp burners.
3674. Lighbody, W. ..... Lamp burners.
3675. Walker, J. ..... Piston and gland packing.
3676. Walker, J. ..... Lubricators.
3680. Pugh, D. ..... Sanitary traps.
3682. Scott, R. ..... Manufacture of corks.
3683. Oriolle, P..... Fire extinguisher.

10th March, 1888.

3702. Anderson, H. ..... Gas regulators.
3716. Ibbotson, E. C..... Lock nuts.
3718. Klauke, C..... Barbed wire for fencing purposes.
3719. Schaefer & Stolberg Horseshoes.
3720. Bunting, S..... Apparatus for filling bottles.
3725. Blakey, J. W. ..... Paring the edges of soles & heels.
3733. Taylor, E. K. ..... Tricycles.
3736. Mills, B. J. B..... Oil lamps (*Weisensee*).
3738. Dean & Groves ..... Padlocks.
3743. Garrard, G. M. ..... Roofing tiles.
3750. Bouverie & Balch ..... Firing signals.
3754. Valentin, B. W. ..... Brewing.
3759. Kubin & Siersch..... Explosives for use in mines.

12th March, 1888.

3768. Gould, H. I..... Lamp burners.
3772. Barclay, J..... Drain pipes.
3774. Wade, J. L. ..... Solidified oil for lubrication.
3777. Wisken, H. ..... Horseshoes.
3778. Rose, G..... Lamps.
3781. Stead, T. W..... Clip employed in machines for stretching woven fabrics.
3783. Williams, S. R..... Oil lamps.
3784. Gibbons, F. J. J..... Locks and latches.
3787. Pearce & Beardsley... Manufacture of paper.
3795. Coninck, F. de..... Incombustible paint.
3797. Shone & Ault..... System of sewerage.
3803. Haddan, H. J. ..... Sliding cocks (*Emery*).
3816. Hainsworth, F. ..... Wire fabric for mattresses.
3822. Moss, J..... Miners' lamps.
3828. Davey, J. ..... Syphons.

13th March, 1888.

3830. Pitt & Van Vleck ..... Distilling petroleum.
3832. Schnell, J. F. ..... Lamp.
3836. Godwin & Hamilton... Protecting wooden picking sticks by a metallic shield.
3838. Brown, A. O..... Regenerative gas lamps.
3844. Bullus, G..... Wheel for iron or rubber tyres.
3865. Varley, F. H., & others. Lamps.
3868. Stevens, B. F. ..... Hose nozzle (*Brentano*).
3870. Wing, J..... Ships' fittings.
3872. Russell, R. J. ..... Bicycles.
3888. Boult, A. J. ..... Door hinges (*Timmel*).
3893. Thomas, G. ..... Hasp locks.
3902. Rogers, G. F. ..... Testing explosives (*Von Ruckteschell*).
3917. Auton, R. ..... Briquettes of compressed fuel.
3919. Neate, P. J. ..... Rotary sieves.

Digitized by Google

14th March, 1888.

3936. Noar, F. C. ..... Cinder sifter.
3942-3. Cherrill & Schlichter..... Incandescent gas lamps.
3950. Anton, R. ..... Briquettes of compressed fuel.
3956. Dean, J..... Lubricators.
3976. Leigh, H. H. ..... Heating liquids to be treated in centrifugal separators (*Bernström*).
3980. Kreiss, E..... Dust collectors.
3989. Dresser, C. L..... Explosive projectiles.
3990. Everitt, R. ..... Drying sugar (*Taylor & Lawson*).

15th March, 1888.

4010. Farrar, J. W., & others Automatic fog signal.
4026. Venimore, T. A. ..... Taps.
4033. Dimmack, A. ..... Slip bolts.
4040. Brewster, P. C. ..... Lamps (*Ehlis*).
4041. Allen, F. J. B..... Extinguishing devices for lamps.
4045. Vogt, A..... Washers and nuts.
4046. Vogt, A..... Locking nuts.
4053. Macer, R..... Setting screws.

COMPLETE SPECIFICATIONS ACCEPTED.

Persons interested in opposing the grant of the following patents may give notice of opposition at any time within two months after the dates given.

ENGINEERING.

17th March, 1888.

3656. Sage, F..... Frame work fences.
3660. Redfern, G. F..... Fluid pressure motor (*Fouquemberg*).
3662. Baxter, W. ..... Finishing textile fabrics.
3689. Beck, W. H. ..... Surfacing cylindrical glasses (*Benoist et Berthiot*).
3744. Richardson & Rowland Valve gear.
3769. Smith, T. ..... Preventing over-winding of engines.
4131. Ross & Bilbie ..... Boot and shoe machinery.
4156. Schofield, I. C. ..... Winding the yarn on to the spindles of mules.
4659. Maynes & Watchurst Steam engines.
5013. Teideman, G. ..... Liquid meters.
5271. Dallas, J. D..... Apparatus for setting up type.
5389. Lake, H. H. ..... Knitting machines (*Boessneck*).
5710. Armstrong, J..... Manufacture of rolled glass.
6136. Smith, E. ..... Automatic motion for stopping the loom when the warp thread breaks.
6240. Cranston, W. M..... Mowing machines (*The Walter A. Wood Mowing and Reaping Machine Co.*).
6586. Ashworth & Ashworth Carding engine.
6773. Buchanan, J. ..... Indicators for steam engines.
6854. Johnson, J. Y..... Disappearing gun mountings (*La Société Schneider et Cie*).
6857. Caillé, J. C..... Permanent way of railways.
6865. Hipkins, T. ..... Steam boilers.
6889. White & Carson..... Boiler furnaces.
6901. Ashworth & Ashworth Apparatus for forming laps of cotton.
6922. Nordenfelt, T. ..... Gun mountings.
6932. Fielding, J..... Mounting and working turret guns.
6934. Longridge, J. A..... Utilising the recoil of guns.
6945. Bird, G..... Paper making machines.
6999. Sykes, G. D..... Looms.
7003. Booth, J. ..... Machinery for "raising" cloths.
7050. Johnston, W. S. ..... Scutching fibrous plants.
7071. Birchall, J..... Steam generator heated by gas.
7081. Garvie, J..... Excavators.
7195. Nordenfelt, T. ..... Breech mechanism for ordnance.
7604. Lawson & Dear ..... Spinning machinery.
7845. McLaine, L..... Flax spinning machinery.
7941. Ash, E. T..... Punching holes in metal.
8502. Hen, L. ..... Manufacturing barbed wire.
11578. Shepheard & Holman.. Adjusting guns to the proper angle of elevation.
15326. Bordone, J. P..... Steam boilers.
16735. Bosley & Dickson ..... Pulley.
17182. Lancaster, C. W..... Doubling and twisting yarn.
793. Webster, G. T. ..... Mitre planing machine.
801. Smith & Smith..... Twist lace fabrics.
1061. Thompson, W. P..... Valves (*Barnett Brass Co.*).
1467. Marshall, C. A. ..... Seamless tubes.
1501. Morrin, T. F. ..... Steam generators.
2074. Hollingworth, E. ..... Jacquard mechanism of looms (*Hutchins*).
2123. Dietz, H. ..... Pneumatic separator for granulated materials.
2143. Hollingworth, E. ..... Jacquard mechanism in looms.
2175. Justice, P. M. ..... Spinning machines (*Metcalf*).
2216. Moyer & Youlls..... Car axle boxes.
2249. Tuck, N. L..... Block printing machines.
2300. Marchetti & Mellor... Manufacture of a new kind of pile fabric.

ELECTRICITY.

17th March, 1888.

16273. Desroziers, E..... Dynamo-electric machinery.
4545. Abel, C. D..... Electrical measuring apparatus (*Siemens & Halske*).
4714. Amoric, F. A. ..... Electrical signal bell apparatus.
5186. Trotter & Goolden ... Dynamo-electric machines.
6409. Crompton & Kyle ..... Dynamo-electric machines and motors.
6681. Crompton, R. E. B..... Secondary batteries.
7317. Kynoch & Habgood ... Secondary batteries.
8262. Mordey, W. M. ..... Electric generators.

CHEMISTRY.

17th March, 1888.

3669. Schultze, C. B. ..... Recovery of tin from tinned iron plate.
5953. Kern, A. ..... Methylic ether of gallic acid.
6718. Grimshaw & Kenyon... Zinc sulphide.
7047. Vivian, A. P. ..... Metallic alloys.
7139. Edwards, D., & others.. Coating metal plates with tin.
2019. Perino, J..... Disintegrating copper pyrites.
2071. Lake, H. H. ..... Separation of metals (*Hayden*).

MISCELLANEOUS.

17th March, 1888.

3707. Postlethwaite, C. E.... Petroleum lamps.
5264. Smith & Hicking. ..... Velocipedes.
5513. Arper, G. W..... Syphons.
6255. Harrison, F. A. ..... Bolts and nuts.
6368. Reaney, A. ..... Projectiles.
6568. Mewburn, J. C. ..... Lamps (*Cambéssèdes*).
6704. Zohrab, E. ..... Treatment of peat.
6727. Beldam, A. ..... Valves.
6916. Baker & Barton..... Miners' safety lamps.
8301. Braithwaite & Braithwaite..... Gas burners.
15387. Flint, J. G. ..... Stop cocks.
15446. Hattersley, T. K. ..... Adjustable bearings for spindles.
17797. Roberts, L., & others... Spiral springs.
883. Adams, S. H..... Ventilating sewers.
935. Turner, S. ..... Roof tile.
1138. Rankin, A. N. ..... Cold packed pipe joints.
1274. Settle, T..... Relieving gas retorts from pressure.
1402. Paterson, J..... Testing the fairness of steam engine crank shafts.
1428. Allison, H. J. ..... Nuts (*Stout & Underwood*).
2050. Lawrence, J. P. ..... Refrigerating apparatus (*Biddle*)
2113. Lane, J..... Heating fluids.
2117. Carson, J..... Seeding machine.
2164. Wimpey, G. ..... Joint for water pipes.
2221. Megill, E. L..... Gauge pin for printing presses.
2373. Stern, W..... Gas lamps.

PATENTS VOID THROUGH NON-PAYMENT OF RENEWAL FEES.

(*To the 10th December, 1887, inclusive*).

Year 1883.

5624-5. Divine, S. R..... Explosive compounds.
5626. Roos, S..... An electro-telegraphic system.
5628. Johnson, J. H..... Salicylic acid (*Leupold*).
5629. Tolson, G., & another... Opening rags, &c.
5636. Wilcox, S..... Hot air engines.
5637. Clark, A. M..... A woven fabric (*Urbahn & ano*).
5641. Martin, J. H. C. ..... Decorticating grain, &c.
5642. Lake, W. R. ..... Mining coal (*Asper*).
5645. Kilbourn, J. K., & ano. Steering apparatus.
5647. Leeming, H..... Sewing machines.
5648. White, J., & another ... Velocipedes.
5650. Hall, R., & another..... Wood paving.
5652. Thompson, W. P..... Roller mills (*Dowling*).
5658. Thompson, W. P..... Protecting foundations below water level, &c. (*Paponot*).
5667. Hosmer, H. G..... Motive power engines.
5668. Nawrocki, G. W. von... Electric apparatus for fog signals (*Dreyse & another*).
5670. Lake, W. R. ..... Dyeing vegetable and animal substances (*Crébassa & another*).

ABSTRACTS OF BRITISH PATENT SPECIFICATIONS.

Compiled from the Published Specifications by W. E. Heys, 70, *Market-street, Manchester.*

ENGINEERING.

Rotary Engine.—*J. M. Ross & J. McDowall, Glasgow.*—In the accompanying diagrams Fig. 1 represents a longitudinal vertical section, and Fig. 2 an end section of the improved form of rotary engine. The hollow shaft B is supported on bearings X, and passes through the cylindrical casing A. The ports for admission and exhaust of steam are shown at H H¹. The cylindrical boss C is mounted eccentrically upon the shaft B, and is provided with inlet and exhaust ports. A cylindrical ring D is fixed to the main casing A, concentrically with the boss C, and between the boss and the ring is a series of segmental pistons E, filling up the steam space within D, and fixed to the casing A by means of bolts F. As the distance of the pistons from the axis of A varies according to their position around the eccentric boss C, their distance apart also varies, those pistons bearing on the

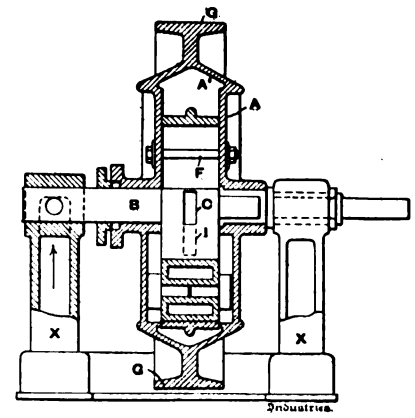

Fig. 1.

portion of the boss with least eccentricity being close together, and those on the opposite side of the boss being furthest apart. When the pistons travel round the eccentric boss, their velocity is therefore greatest at the point of greatest eccentricity; the two ports are formed to admit the steam between each pair of pistons as they pass the point of least eccentricity, and to exhaust when they pass the line of greatest eccentricity. The steam may, however, be cut off at any desired point, and allowed to expand, while the piston in front of it is impelled forward at a greater relative velocity than that following it. Each succeeding piston is acted on in like manner, and a continuous motion of rotation is thus imparted to the outer casing A. The inner casing D is free to rotate with it, and slides to accommodate itself to the radial sliding movement of the pistons relatively with the axis of the casing. The central shaft B is held

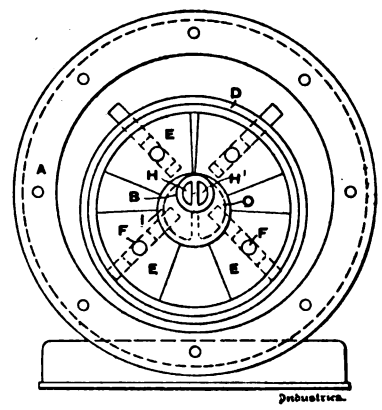

Fig. 2.

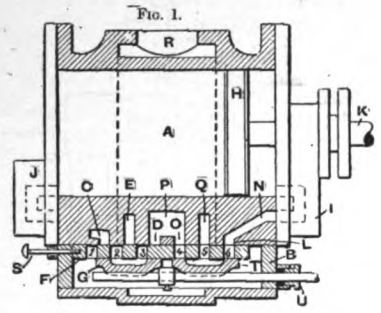
stationary, whilst the case A is formed with a driving wheel round its circumference. The speed and power depend on the degree of eccentricity of the boss, as well as on the area presented to the steam. By fitting the parts so that the eccentricity may be varied, the speed and power may be regulated at will. This adjustment is effected by the end of the hollow shaft B forming a valve in the bracket, with suitable ports, so that steam is cut off or admitted in accordance with the motion of the shaft. The engine is reversed by turning the shaft B, so that the inlet becomes the exhaust port. There are two modifications in the construction of the engine described in the specification. Three claims are made.—No. 4403. March 24th, 1887. 8*d.*

Steam Engines.—*P. Haddan, London.* (*Dake Engine Manufacturing Company, Grand Haven, Michigan, U.S.A.*)—This engine has two rectangular pistons which act as their own valves. An outer rectangular shell encloses a cubical piston, inside which the second piston slides in a direction at right angles to the first one. The inner piston has two separate internal steam chambers. There are no valves worked by special gear, but a series of ports are so arranged in the two pistons that they act as their own admission and exhaust valves. The inventor makes four claims for this construction, and for the arrangements of the ports and passages.—No. 6679. May 6th, 1887. 8*d.*

Digitized by Google

VALVE GEAR.—*H. H. Lake, London.* (*K. Knott & F. Knott, Chicago, U.S.A.*)—A movable plate, with two sets of ports in it, acts in combination with two sets of ports in the cylinder, and with two slide valves attached to a common rod and operated by a single eccentric. In the accompanying drawings Fig. 1 is a longitudinal central section of an engine cylinder and steam chest, showing the movable or "dead" plate at one end of its movement. Fig. 2 is a similar view, showing the dead plate at the other end of its stroke. The exhaust port L communicates with the end I of the cylinder A through the passage N, and the steam port C also communicates with the same end. The ports D O communicate with the end J of the cylinder, and the exhaust ports E Q are connected with the exhaust pipe by means of the passage R. The dead plate F lies between the cylinder and the slide valve, and is provided with two sets of ports 1 2 3 and 4 5 6 corresponding to the cylinder ports C E D and L Q O respectively. The two slide valves G T are united and are operated by the stem V. The ports in the plate F are not placed at the same distance apart as the cylinder ports are, and therefore the communication between the steam chest and the cylinder will only be established through one set of ports at a time. In Fig. 1 the ports C E D are shown covered by the dead plate, while the ports L Q O are open. In this case the steam is distributed by the slide valve T through the passages 4 5 6. By shifting the dead plate F by means of the rod S communication may be established between the steam chest and the cylinder

FIG. 1.



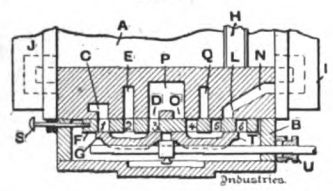


FIG. 2.

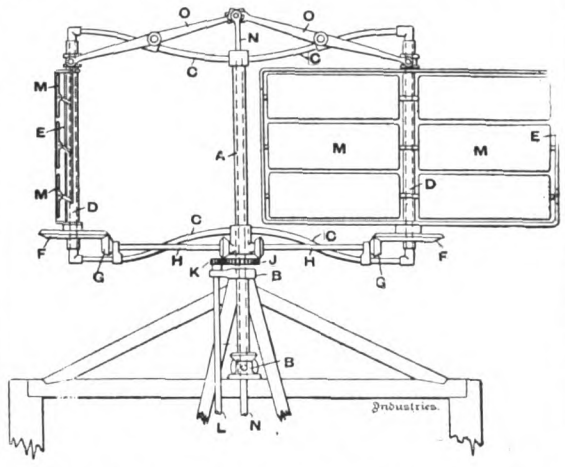
through the set of ports C D E, while L Q O are covered by F. The slide valve is so arranged relatively to the ports which they cover, that when the course pursued by the steam is altered from one set of ports to the other, the engine shall be reversed in direction. Several modifications are described for carrying out this invention and in applying it to different types of engines. In order to give the valve the required amount of lead in the two directions of revolution, the eccentric is mounted loosely upon the crank shaft, and upon one side of it a small auxiliary eccentric is arranged. A driving block, having an opening adapted to receive the small eccentric, is keyed to the driving shaft at right angles to the crank. The throw of the small eccentric corresponds to the required lead, so that its rotation in either direction will shift the valve eccentric relatively to the driving block. To give an automatic action to the small eccentric a lever is attached to it, which impinges upon a stud on one of the straps of the valve eccentric. When the reversal takes place the lever will strike the abutment and cause it to turn through 180°, thereby causing the required movement of the valve eccentric. The inventors make nine claims for slide valve and dead plate arrangement, and for the eccentric gear.—No. 988. January 21st, 1887. 11*d*.

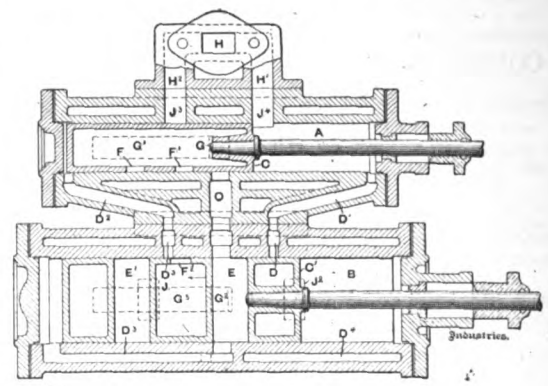


HYDRAULIC LIFTS.—*W. R. Green, London.*—The means of communicating the motion of the lifting ram to the lifting chains in a suspended hydraulic lift is improved and re-arranged by the present inventor. The sheaves forming the multiplying power have hitherto been carried by a cross head fixed to the ram. According to the present arrangement the cylinder is inverted, so that the ram works downwards. Two or more vertical rods are attached to the end of the ram, and pass upwards through guides attached to the cylinder. These rods are continued upwards, and are fastened to a cross head carrying the pulley sheaves. The usual heavy cast iron cross head can thus be dispensed with, and the pulleys may be made of an increased size in consequence. The extra foundations for the guides are not necessary, as these are carried entirely by the cylinder. The inventor claims the employment of two or more side rods to convey the motion of the ram to the pulley sheaves, passing through guides attached to the cylinder.—No. 5520. April 15th, 1887. 8*d*.

RETIRING BEARINGS FOR TRAVELLING CRANES, &C.—*W. Craven, Manchester.*—At the point in the length of the side shaft of the crane where the retiring bearing is required a bracket is fixed in position to any stationary part of the machine. The retiring bearing is supported in a vertical groove in this bracket. A crank pin fixed to a crank and short shaft slides in a horizontal slot in the retiring bearing, and controls the motion of the bearing in the vertical groove. A series of teeth are fixed to the circumference of a wheel attached to the short shaft before mentioned, and are intended to gear with a toothed rack on the carrier. The bearing is lowered from its normal position for the passage of the carrier by the teeth of the rack causing the crank pin to be depressed, and a second rack on the carrier effects the raising of the bearings after its passage in a similar way. The inventor makes two claims.—No. 18. January 2nd, 1888. 6*d*.

WATER MOTORS.—*S. S. Allin, London.*—By this invention certain improvements are introduced into the construction of the motor described in Patent No. 11994 of 1885, granted to the same inventor. The object is to cause the floats to feather mechanically and without any motion relative to the links to which they are connected. The pins passing through the eyes of the links are made to project inwards through those links for a sufficient distance to support brackets opposite each other. These brackets are provided with holes for the entrance of the link pins, so that when they are in place they are supported in positions parallel to the links. The lower extremity of each bracket terminates in a foot at the forward end of its link, and braces of channel iron extend from the bracket on one chain to that on the other, and are secured firmly to both. The pair of brackets and the braces form a rigid cradle which carries the float. In small motors the cradles may consist of a pair of links of the chains, and braces extending from one to the other may be secured to projections on the links. The inventor makes three claims.—No. 5145. April 6th, 1887. 8*d*.

ROLLING MILLS.—*W. F. Cochrane, Cambridge, Indiana, U.S.A.*—The improvements embodied in this invention relate to a new construction of the frame of the machine, and to a new method of communicating motion to the driving shafts. The sectional frame consists of two duplicate side pieces, and of tubular cross bars and through rods which connect the side pieces. The side bars are slotted for the reception of the adjustable bearings of the rolls, and are provided with a recess at the end to receive the disc of the relief mechanism. The detachable pulley frame is composed of end plates and upper and lower divided side bars bolted together. Hangers are held adjustably between the sections of the upper side bars, and links pivoted to the lower side bars carry the frame for a tightener pulley. Parallel driving shafts each pass longitudinally through one series of adjustable rolls, and pulleys are mounted upon these shafts; the tightener pulley is placed between the shafts, and the driving belt passes beneath the tightener pulley, over the front and beneath the rear driving pulleys. Fifteen claims are made.—No. 15239. November 8th, 1887. 8*d*.



WIND MILLS.—*C. Hawkins, London.*—The object of this invention is to make the sails of a wind mill adjust themselves continuously to receive the force of the wind. Rectangular sails are employed which present their surface in the most favourable way as they revolve round a vertical or horizontal axis. When the sail is moving directly towards the wind the edge is presented to it, and when moving with the wind the surface is at right angles with its direction. In the accompanying illustration one method of carrying out this idea is represented. The hollow vertical axle A is supported in bearings B; the arms C are attached to it in pairs. Across the ends of each pair of arms is fixed the rod D, which ties the arms firmly together, and upon each of these rods is pivoted a rectangular sail E. A toothed bevel wheel F is attached to each sail, and gears with a pinion G on the horizontal shaft H. Another pinion I on the shaft H gears into a wheel J concentric with but loose upon the axle A. This wheel J is the adjusting

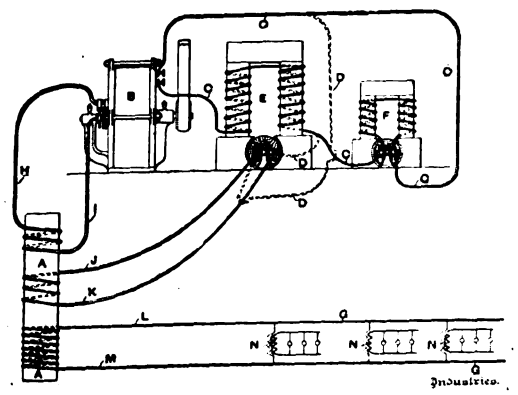
wheel, and according to the position in which it is set so will the sails adjust themselves relatively to the wind. On the lower part of J the spur teeth are cast, which gear with a pinion K on the shaft L. The relative sizes of the wheels are arranged so that the sails shall revolve on the rods D through half a revolution and in a contrary direction to the main axle, while the latter turns through a complete revolution. The wheel F is double the diameter of J. Each sail carries hinged louvre boards M, which are opened and closed by the levers O and N in order to regulate the power supplied to the machine. The inventor makes three claims for the apparatus which effects the continuous adjustment of the sails.—No. 2953. February 25th, 1887. 8*d*.

VALVE GEAR.—*R. W. Mewes, Blackhill, Durham.*—The usual reversing lever is entirely dispensed with, and the valve gear is worked from the regulator handle instead. When this invention is applied to a locomotive, a slot link is provided for working the slide valve, and adjusting screws vary its travel, so as to cut off at any part of the stroke. The regulator handle being at the centre may be moved to the right or left, giving forward or backward motion by means of a slide, which admits the steam to one end or the other of the reversing cylinder. This cylinder moves the slot link one way or the other as desired. There is also a crank on the spindle of the operating handle for actuating the valve for the admission of steam to the main cylinders, so that the first motion of the handle, one way or the other, moves the valve in a direction so as to reverse the engine. Afterwards, on the continuation of the motion of the handle, the throttle valve is opened to an extent depending on the amount of travel of the handle. The reversing cylinder and the main cylinders are supplied with steam through separate pipes. Four claims are made.—No. 5598. April 18th, 1887. 8*d*.

STEAM ENGINES.—*C. D. Abel, London.* (*J. C. Grabner, Kupferhammer, and C. Ruperti, Brackwede, Germany.*—According to this invention, the steam is admitted to both sides of the piston by means of specially constructed passages and ports in the cylinder and piston, and the slide valve arrangement is entirely dispensed with. The application of this method to a compound engine is seen in section in the accompanying drawing. A is the high pressure cylinder, and B the low pressure one. The pistons C C¹ are made hollow; C¹ is provided with a longitudinal slot G¹ and ports F F¹, while C is formed with a slot G³, port F², and cross passages E E¹. The pistons act as each other's slide valves. In the position of the pistons shown in the drawing, the piston C¹ has still part of its stroke to travel through, while C is at the commencement of its forward stroke. The steam enters the cylinder B through the port G², and passes through G³ to the interior of the piston C¹. Thence it escapes through F², along the passage D², to the back of the piston C. The exhaust of the steam at the front of the piston C takes place through the passage J⁴, whence it goes along the tube H and enters the piston C through the port G and slot G¹. When the port F¹ comes opposite O, the steam escapes, and

travels across the piston C¹, through the passage E¹, along the pipe D³, to the back of the piston C¹. After performing its work there, it escapes to the atmosphere through the ports J¹. When the piston C is at its dead centre position at the right end, the piston C¹ has still a part of its stroke to travel. The steam passes through F² D D¹, and drives C to the left. The same series of operations takes place with respect to the exhaust steam from the back end of the cylinder A as with the steam at the back of the piston, but it comes through J³ H F O¹ E¹ D⁴ J². There are also single cylindered engines described in this specification, whose pistons act as their own slide valves. The steam enters through a port in the cylinder, and passes through a slot into the interior of the piston. There are ports at each end of the piston, and the ends of the cylindrical part of the cylinders are broadened, so as to allow the steam to escape through the ports to the back of the piston. The exhaust also takes place through a port in the side of the cylinder. Six claims are made.—No. 6238. April 28th, 1887. 11*d*.

SUGAR CANE MILLS.—*J. Thomson, Edinburgh, and J. Black, Kirkaldy.*—By this invention certain improvements are introduced into the construction of the apparatus described in the specification of Patent No. 2586 of 1882. In the apparatus there referred to the same inventors made use of two rollers for the purpose of subjecting the cane to a preparatory splitting and crushing action, with a view of bringing it into a condition to be more completely acted on by the three ordinary rolls. The object of this present invention is to improve the action of these two additional rolls, by constructing them in such a manner that they shall not only split the canes, but shall also break them transversely. With this object the two rollers are made with rounded flutes, and are geared together so that the raised parts of one roll may enter the depressed parts of the other. Angular grooves are also made in the rolls for effecting the splitting operation, and run at right angles to the flutes, or are inclined to them. These rolls may be either combined in one framing with the three others, or they may be mounted in a separate frame; in the latter case they may be easily added to existing three-roll mills. The inventors make one claim for the combined flutings with the transverse grooves.—No. 5660. April 19th, 1887. 8*d*.



KNITTING MACHINERY.—*H. J. M. Mellor, Nottingham.*—This invention relates to certain improvements in the machinery employed in knitting jerseys. A cylindrical needle head carries latch needles all round it, which can be moved up and down by cams carried by a ring surrounding the exterior of the cylinder. The ring also carries a third ring, upon which the thread guides are mounted; and there are as many sets of cams for raising and lowering the needles as there are yarn guides. The cam ring oscillates round the cylinder, and the ring with the yarn guides is carried round by friction with the cam ring; but it is arrested by stops when the requisite travel has been made. This travel is slightly greater than the distance between the yarn guides, and a slightly greater travel is given to the cam ring, in order to allow a lead for the yarn. Mechanism is provided for lifting the needles out of work, in order to prevent the loops of old work being knocked off when no new thread has been laid on them. Vertical stripes may be produced in this way, and where the stripes meet the work is formed on each needle. One needle at the meeting of the stripes has work formed on it alternately, first with thread from the thread layer used for forming one stripe, and then at the next course with thread from the thread layer used for forming the adjoining stripe. The stripes of work overlap one another on one or more needles where the stripes meet. There may be as many stripes formed in the work as there are thread layers. All the cams carried by the oscillating ring are made to act upon two opposite arms of levers which are coupled to the needle stems at one end. Three claims are made.—No. 3734. March 11th, 1887. 11*d*.

Digitized by Google

ELECTRICITY.

PREVENTION OF INCRUSTATION IN BOILERS.—*A. J. Marquand, Cardiff.*—The inventor makes use of electricity in order to prevent the incrustation and corrosion of steam boilers, and for removing it when already formed. The terminal of an electric generator, corresponding with the zinc plate of the battery, is electrically connected with the shell of the boiler, while the other terminal is connected to the conductor, which passes through the shell into the water space. The current used is a continuous one, and its direction is the opposite to that of all similar apparatus previously designed. The inventor makes three claims for the method and for the apparatus employed.—No. 8396. June 10th, 1887. 8*d.*

ELECTRICAL TRANSFORMER.—*R. Dick & R. Kennedy, Glasgow.*—The reversal of magnetism in the cores of transformers consumes the energy by converting it into heat. To obviate this loss the present inventors construct the machine so that no reversals of magnetism are necessary. The transformers are wound with primary and secondary circuits for the alternating currents in the usual manner, and a third circuit for the circulation of an independent continuous current is employed for initially magnetising the core of the transformer. This third circuit may be wound side by side, either over, under, or between the two other circuits. The continuous current may be supplied by a continuous current dynamo, or by a shunt from the generator

which excites the field magnets. The accompanying diagram represents a general view of the application of this invention to a practical system of electrical distribution. B is the alternating dynamo, E the continuous current dynamo, and F a small separate continuous current dynamo, which excites the field magnets of both B and E, through the wire C. Round the main transformer A is coiled the primary wire circuit H I, from the commutator brushes of the alternating dynamo B. The secondary wire L M supplies alternating currents, induced by the wire H I, to the secondary generators and glow lamps N arranged in parallel arc at G. The third circuit is shown at J K, and is wound round the main transformer A; a continuous current passes through it from the commutator brushes of the dynamo E. The dotted lines D indicate how the field magnets of B can be excited by a current from the continuous dynamo E, and the third circuit supplied with a continuous current as a shunt from the commutator brushes of E. The dynamo F is not required under the latter arrangement. The inventors make three claims for the combination of a transformer with primary and secondary conductors of alternating currents, with a third conductor of continuous currents as described, for the purpose of obviating the reversal of magnetism in the core of the transformer.—No. 3658. March 10th, 1887. 8*d.*

DYNAMOS.—*G. Kapp, London.*—This invention consists of improvements in continuous current dynamos, and is applicable to those which have drum or disc armatures. In machines of the latter type the core of the armature is preferably constructed partly of soft iron wire and partly of soft iron tape. The tape is comparatively narrow; two tapes are coiled to form the end faces of the core, and the iron wire is coiled into the annular trough thus formed. The object of employing narrow tapes and iron wire is to facilitate the penetration of the core without undue heating by magnetic lines of force in other directions than those which are parallel to the axis of rotation. The magnetic field may be either bipolar or multipolar; but in all cases the magnetic system is split up into two portions, one of which is excited by coils in series and traversed by the armature current. This portion of the system may be called the "normal field," and the second portion may be called the "auxiliary field." The pole pieces of the auxiliary field are arranged a certain distance in advance of the pole pieces of the normal field, so that each individual wire on the armature, after passing the neutral zone, comes under the influence of the normal pole piece before it is influenced by the auxiliary pole piece of the same polarity. The reversal of the current in the wires passing under the brushes takes place when the normal field only is active, and thus any variations in the strength of the auxiliary field do not materially affect the best positions of the brushes for the sparkless collection of the current. Two armatures may be employed instead of one, and may be mounted on the same spindle; one armature will revolve in the normal field, and the other in the auxiliary field. For purposes of regulation the inventor varies the exciting current in the auxiliary field. This may be done by hand, or by the following arrangement in cases where the resistance and speed are variable. The armature, normal field, auxiliary field, and external circuit are all coupled in series. If the auxiliary field is of the single horseshoe type, a shunt rheostat is placed across the terminals of the exciting circuit. If the field is of the double horseshoe type, the rheostat may be arranged as a shunt in the exciting circuit of one horseshoe only. The contact pieces are grouped round an insulating cylinder in a similar manner to the sections of the commutator of a continuous current dynamo. A brush capable of rotation round this commutator serves as the movable contact, and according to its position, which is controlled by a solenoid, the amount of current passing through the rheostat and the exciting circuit of the auxiliary field may be varied. The solenoid is in circuit with the main current, and is counterbalanced by an adjustable weight. Nine claims are made for the construction of the dynamo and for the governor.—No. 5096. April 5th, 1887. 8*d.*

DYNAMOS.—*W. Main, Brooklyn, New York.*—The invention here described is one of several modifications explained in the specification. Fig. 1 represents a vertical section of the machine in the plane of its rotation, and Fig. 2 gives a front view partly in section. The field magnet F consists of a core B, surrounded by the exciting coil E. The tube B is confined between the polar discs L^1, which are formed with eight radiating pole pieces L. The field magnet and its coil are

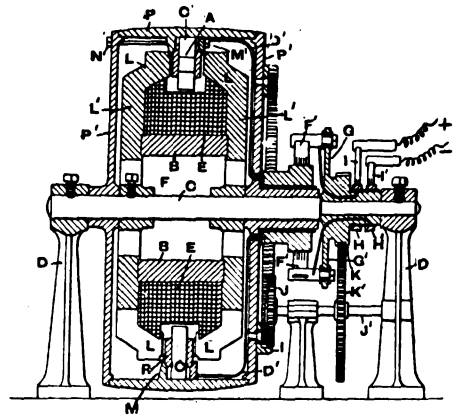


FIG. 1.

held stationary, and are fastened to the shaft C. The armature A revolves, and is mounted on the shell P, which serves also as a pulley for carrying the driving belt. The fixed flange M and the ring M^1 hold the armature between them. The armature has sixteen coils, while the field magnet has nine pole pieces. If the armature were stationary, and the pole pieces revolved, the neutral line in the armature would revolve forward with nine times the rapidity of the poles. But as in this machine the armature revolves forward while the field magnet is stationary, the neutral line revolves backwards with eight times the velocity of the armature. This may be accomplished by means of stationary commutator brushes and a commutator of nine successive series of sixteen segments in each. In the machine shown in the drawings the same effect is obtained by rotating the commutator brushes backward at a speed of eight revolutions while the armature and commutator segments are revolving forward through one revolution. The commutator segments E^1 are carried on the hub of one of the discs P^1, attached to which is an internal gear I. A pinion J on a shaft J^1 transmits the motion through K^1 to K, which turns freely in the stationary shaft C. The proportions of the various parts of this gear are such that the rotation of I in one direction causes a rotation of K at eight times the velocity in the contrary direction. Attached

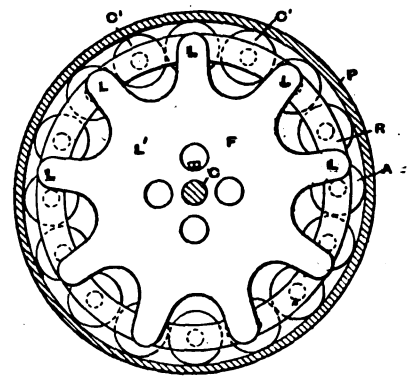

FIG. 2.

to the pinion J are the brush arms G G^1 carrying the brushes F F^1. These are connected respectively with two insulated rings H H^1, which are swept by two take-off brushes I^1. The iron armature rings R are chiefly desirable when the machine is used as an electromotor. The armature cores may be omitted, in which case the coils C^1 should be made flat and thin, in order to bring the opposite poles L as near together as possible. It is characteristic of all the modifications described in this specification that the ring armature is wound so as to develop alternate north and south poles presented to the poles of the field magnet as the armature is traversed circumferentially, and that there may be any suitable number of magnetic poles on the armature. Fifteen claims are made.—No. 15858. November 18th, 1887. 1*s.* 1*d.*

VARIABLE ELECTRIC CURRENTS.—*J. C. Mewburn, London.* (*La Société Anonyme pour la Transmission de la Force par l'Electricité, Paris.*)—This invention consists of apparatus whereby a part of the main electric current may be shunted to a derived circuit, without expending the remainder in useless work. A counter electromotive device is introduced into the main circuit, and into the derived circuit thus obtained another counter electromotive device is introduced. These devices may be two induced rings or armatures of dynamos. The two rings are mechanically connected by being keyed to the same shaft. If the inductors for the main circuit are alone excited this device will produce a counter electromotive force equal to the difference of potential engendered by the main current between the connecting points; this force will therefore be taken up by the derived circuit with its whole intensity. If, on the other hand, the inductors in the derived circuit are alone excited, this device will take up all the power and prevent any current passing into the derived circuit, with the same result as if this circuit did not exist. If the inductors of both devices are excited together, they will each receive a counter electromotive force in proportion to the magnetic field given to it; the current will be divided between the main circuit and the derived circuit in the inverse ratio of these forces. The proportion of the intensity of the current which is derived to that of the remaining current may thus be regulated at will. When the counter electromotive devices employed are armatures or rings, the inductors may be supplied from the main current, either by a simple winding or by a double winding. By dividing the circuits wound on the inductors into sections leading to a commutator, the current can be sent into any desired number of the sections. By moving the commutator the sections traversed by the exciting current may be only those of the inductors connected with the device in the main circuit, or only those of the inductors in the derived circuit, or partly one and partly the other. The counter electromotive forces can thus be modified at will. Two claims are made.—No. 6972. May 12th, 1887. 8*d.*

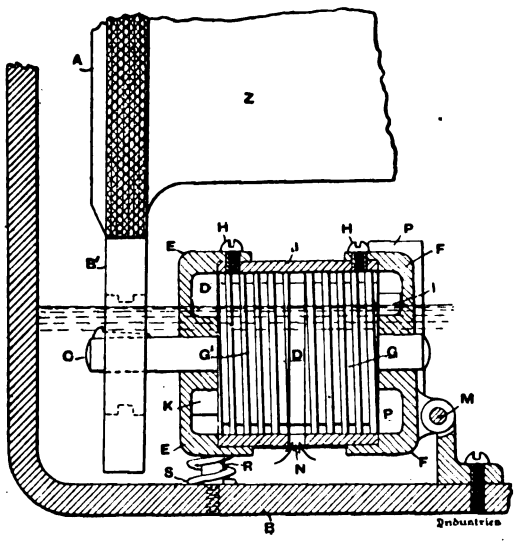
CHEMISTRY.

ALUMINIUM.—*E. de Pass, London.* (*M. Bernard & E. Bernard, Paris.*)—The inventors here modify the process of extracting aluminium by electrolysis from the chlorides and fluorides of aluminium and sodium. A bath is formed in which the aluminium fluoride or double fluoride of aluminium and sodium is employed as the principal electrolyte. The greatest yield of aluminium is found to be when its fluoride is in a melted state without being mixed with any other salt. Very good results are obtained by using forty parts of aluminium fluoride with sixty of common salt. If pure aluminium is required the two electrodes are of carbon; and for obtaining aluminium bronze the electrodes are carbon and copper. The crucible may be of refractory earth or of metal. Five claims are made.—No. 10057. July 18th, 1887. 8*d.*

MANUFACTURE OF DEXTRINE.—*A. Schuhmann, Strassburg, Germany.*—This invention is designed with the object of producing a commercial dextrine, which is free from any disagreeable odour. Starch flour is mixed with fresh water until it arrives at the consistency of a thick milk, and one per cent. of a fixed acid is then added. The mass is well stirred and left for twenty-four hours, after which interval the acid water is decanted, and the precipitated starch is washed. This pure starch is then mixed with fresh water, so as to form a milk of 15°Bé, and to this mixture is added one-half per cent. of sulphurous acid. The mass is then boiled in a digester at a pressure of three atmospheres. As soon as any glucose makes its appearance, the treatment is stopped, and the material is filtered through charcoal, from which it issues as a clear liquid without taste or smell. This process is also said to be less expensive than the ordinary one, as large quantities can be prepared at one time. Three claims are made for this process.—No. 5460. April 14th, 1887. 6*d.*

COATING METALLIC ARTICLES WITH TIN.—*A. E. Barthel, New York, and J. C. J. Möller, Hamburg.*—In preparing the metallic objects before exposing them to the molten tin, the inventors make use of an electrolytic bath, in order to impart to the object a surface of chemically pure iron. The bath is composed of 600grm. of sulphate of iron dissolved in 5 litres of water, together with a solution of 2400grm. of carbonate of soda in 5 litres of water. The resulting precipitate of carbonate of iron is dissolved in as much concentrated sulphuric acid as will cause the fluid to assume a green colour. The bath is then rendered aqueous by adding 20 litres of water. The objects to be provided with a coating of chemically pure iron are placed in the bath in a position opposite to the anode of cast iron, and both parts are connected to the corresponding poles of a dynamo or electric battery. After this process is completed the objects are immersed in a solution of ammonia in chloride of zinc, and immediately afterwards plunged into the molten tin. It is found that the resulting coat of tin adheres with great tenacity to the chemically pure iron surface. Two claims are made.—No. 17356. December 17th, 1887. 4*d.*

MISCELLANEOUS.



DYEING FABRICS—*W. J. S. Gravitz, St. Maur-les-Fossés, France.* In dyeing vegetable and animal textile materials before spinning, the inventor employs a hollow cylinder of wire work. The material, in the form of lap from the scutcher or sliver from carding engine, is wound upon the hollow cylinder, and is retained in its position by a second open work cylinder, concentric with the first. A very large bobbin is thus formed, which is afterwards keyed upon a horizontal shaft over a dye vat. The bobbin is partly immersed in the liquor, and the usual operations of boiling, mordanting, and dyeing are proceeded with. Rotary motion is imparted to the bobbin, and thus the material is not disarranged in the slightest, and can afterwards be submitted at once to the ordinary process of spinning. The inventor makes one claim for the method of dyeing the materials before spinning, by placing them between the two concentric open work cylinders.—No. 13445. March 4th, 1887. 6*d.*

SWING BUCKET.—*A. Thomas, Cardiff.*—The improved bucket is intended for use in loading and unloading ships and waggons, and is provided at one side with a pair of spring bolts which are carried in hinged sockets. When the bucket is attached to the chain, in order to be filled, the handle lies at one side between the tongues of the spring bolts, and the bucket is not free to revolve within the handle; but when the loaded bucket is set upon its bottom, and the tension in the chain relaxed, the handle drops, and a notch on it is brought in contact with the tongues of the spring bolts, which are thus forced back into their sockets. To enable the handle to drop in this way it is slotted, and the neck of the trunnion rests in the slot. If the chain is now drawn up, the bucket turns over and discharges its contents. After discharge the bucket swings back again into its former position, and the handle becomes locked again between the spring bolts. The trunnions are placed sufficiently

Digitized by Google

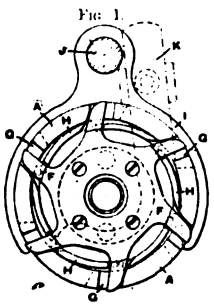
low on the sides of the bucket to ensure its swinging freely when the handle is released and the bucket raised. When it is required to prevent the bucket from tipping automatically, a pawl, hinged to the handle, is made to bear upon the neck of the trunnion, and the descent of the handle is thereby obstructed. Three claims are made for the construction of this automatically tipping bucket.—No. 436. January 11th, 1888. 6*d*.

LUBRICATORS FOR AXLE NECKS.—*J. Loesewitz, Witten, Prussia, and G. Moass, Duisberg, Prussia.*—This invention relates to an apparatus for lubricating the axle necks of railway cars in such a manner that no oil can escape and no dust enter. With the movement of the neck the oil is continually conducted over the axle. The method will be understood by reference to the accompanying diagram, which represents a longitudinal section

through part of the bearing box. The axle neck Z is provided with fine corrugations on its head A, which is in gear with the rubber disc B¹. The screw piston D rests in the cylindrical covers E and F, which are fixed on the cylinder J by means of the screws H. The paddles I and K rotate in the grooves at the ends of the case E F. At both sides of the covers E F are the two pins R, over which are placed the spiral springs S, supporting the shoulders of E F. The whole apparatus is connected to the bottom of the bearing box B by means of a pivot M. As it is supported only by this pivot and the springs S, the transference of the vibration of the axle neck is avoided, and the rubber disc B¹ is always kept in contact with the head A¹. The cylinder J has an opening N in it for the introduction of the oil; the case F is provided with a vertical channel P, and the case E with a similar one for conveying the oil above the axle neck Z. A leathering is arranged in a groove in the bearing box, and a spring ring presses the leathering against the walls. The apparatus E F is surrounded with oil, and on the rotation of the screw piston the oil is conducted through the opening N. The paddles I then force it up through the channel P, and a tube carries it above the leathering on the axle neck. The oil flows down again into the reservoir, and is made use of an indefinite number of times. The apparatus being entirely closed, the air and dust cannot enter, and the oil cannot escape. There are five claims for this lubricating apparatus.—No. 17783. December 27th, 1887. 8*d*.

BOOT AND SHOE MACHINES.—*A. V. Newton, London.* (*J. Keats and H. C. Keats, Frankfurt-am-Main.*)—The object of this invention is to construct the rotary compound cutters of boot and shoe sole paring machines in such a manner as to obtain a uniform depth of cut from the profile cutters, notwithstanding

FIG. 1.



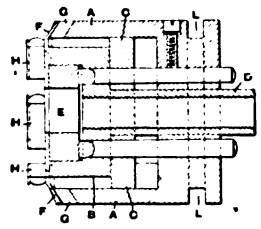


FIG. 2.

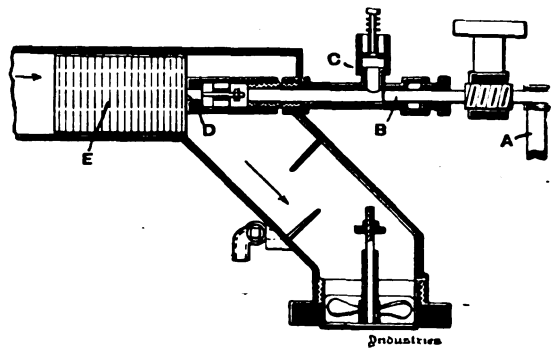
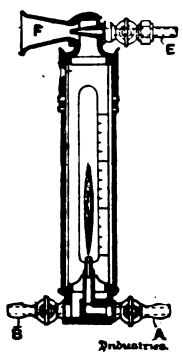


the wearing away of their cutting edges, and also to provide for the adjustment of the chamfering or face cutter relatively to the profile cutters, in order to suit the work in hand. In the accompanying diagrams, Fig. 1 gives a front view and Fig. 2 a longitudinal section of the cutter. The essential parts are the sleeve A, the profile cutter holder B, and the chamfering cutter holder E. The profile cutters H are segment-shaped from their front edge to their heel, and are fitted in rebates cut in the periphery of the block B, so as to give them an eccentric set. The disc C is screwed to the back of B, and receives the sliding sleeve A. The hollow centre piece D is cast in one block with B, and is internally threaded to fit on the spindle of the machine. Holes are drilled through B and C, in order to form guides for two parallel rods projecting rearward from the cutter holder E. These rods pass through the rear end of the sleeve A, and the holder E is made fast to the sleeve A by means of a binding screw bearing against one of the rods. The chamfering cutter F is secured to the front of E by means of screws, and recesses G receive the blades of the cutter. The cutters H have a raised part at their outer side for the removal of the burr from the inner angle of the sole. The inventor makes three claims: (1) For attaching the holder of the chamfering cutter adjustably to a sleeve which is capable of sliding over the profile cutter holder; (2) for the construction of the holder and cutters B and H to receive the holder and cutter E and F, and to permit the adjustment of the chamfering cutter to its work; and (3) for the general construction and mounting of the cutters.—No. 2968. February 25th, 1887. 8*d*.

DYEING TEXTILE MATERIALS.—*H. H. Lake, London.* (*U. Weldon, Cohoes, New York.*)—This apparatus consists essentially of a dipping wheel, which rotates in a vat containing the dyestuff. To the axle of the dipping wheel is fixed a series of radial vanes, the outer ends of which are in the form of perforated semi-cylindrical pockets. The cross-section of the wheel thus presents an appearance similar to a series of sickles with their handles fixed to the hub. The fabric is carried up in these pockets, and after arriving at the highest point of the wheel, it drops out again into the liquid. It remains in the dye after half a revolution, and afterwards it is again taken up by the same pocket. The sides of the pocket are made of a series of round rods. These arrangements of the wheel are for the object of insuring a more uniform treatment of the material than has been obtained by machines hitherto in use. Three claims are made.—No. 402. January 10th, 1888. 8*d*.

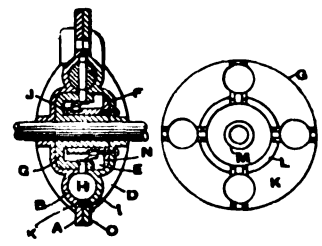


GERMAN PATENT ABSTRACTS.

PETROLEUM ENGINES.—*Boris Lutzky, Munich.*—This apparatus is intended for generating gas for petroleum engines. The piston B¹ receives a reciprocating as well as a rotating motion from the

lever A, thereby sucking oil through the valve C, and forcing it through the valve D against the brush E. In this brush it comes in contact with hot air circulating in the direction indicated by the arrows, and is evaporated.—No. 42290. July 21st, 1887.

FURNACES.—*Schäffer & Budenberg, Magdeburg.*—This invention relates to an apparatus for ascertaining the nature of the gaseous products of combustion leaving furnaces. By means of a sucking arrangement E F a mixture of gases from the furnace



and air is introduced into the apparatus through the tube B. A gas flame is burning inside, which is fed by the tube A. A scale is provided by which the length of the flame may be measured, and from the measured length of that flame a conclusion may be arrived at as to the nature of the furnace gases.—No. 42393. June 10th, 1887.

UNITED STATES PATENT ABSTRACTS.

NUT LOCK.—*H. O. Whyman, Norfolk, Nebraska.*—This nut lock consists of a spiral spring of metal, one end of which tapers to a point. The outer turn of the spiral groove of the nut is cut deeper than the other turns, so as to admit the tapered end of the spring. When the nut has been screwed up into its position on the bolt, the metal spiral is inserted in the deep groove, and effectually prevents any slipping of the nut. Two claims are made.—No. 378563, dated 28th February, 1888.

LOOM.—*H. Eastwood, Paterson, New Jersey.*—According to this invention the depending lay is provided with two or more reeds, and the ordinary shuttle boxes are placed at the ends of the lay and between the reeds. Picker sticks hang from a beam on the lay swords—one from each box—and are connected near their lower ends by straps. They are fastened to the ends of oppositely placed levers, which are pivoted to the beam, and operated alternately from tappets on the cam shaft by means of a system of connecting rods and tappet levers. The sticks are thus thrown first to one side and then to the other, and they drive the shuttles through the several sheds. Springs are employed to bring back the outside sticks, and guides limit and direct the movement of the picker sticks. One claim is made for this improvement.—No. 377425, dated 7th February, 1888.

ROTARY ENGINE.—*D. Williamson, New York.*—This engine consists of only three main pieces, a shaft, a casing, and a revolving disc and vanes. The left hand figure in the accompanying illustration represents a longitudinal section in the plane of the shaft, and the other figure shows a front view of the revolving disc. The case A C is strengthened by the ribs D, and each of the two separate pieces A and C is provided with an annular groove. These grooves form an annular fluid channel H when the cases are riveted together. Inlet and exit ports in the casing allow the fluid to enter and leave the channel H; they are located side by side, and communicate with H on either side of a division wall. This abutment or division wall is in two parts, and fills the annular channel in each of the parts of the casing faces up flush with its edges. A space is thus left between the faces of the abutment. The central chamber E contains part of the disc G and the cam F. The cam consist

of a sleeve having a peripheral cam groove J, and a flange at right angles to the shaft. The disc G consists of a flange, centre box, and sleeve, all cast in one piece. The sleeve M surrounds the shaft and is tightly secured to it, and the flange portion K of the disc is perforated to receive the vanes. A circular shape is given to the vanes, and their thickness is equal to that of the flange K. Each vane is provided with a spindle which runs in one of the bearings of the flange, and which extends through the wall into E. A crank which carries an anti-friction roller is fitted to the end of the spindle, and the roller runs in the cam groove J. The vanes are given a quarter turn while passing through the first quarter of the channel H. They remain in that position until they reach the beginning of the last quarter, when they commence to fold, in order to pass between the faces of the abutment. The number of vanes is preferably four. The space between the faces of the abutment is kept constantly closed by the flange of the disc G, and consequently the entering and exhausting fluids cannot interfere. The entering fluid presses against and rotates the vanes; when the vanes arrive opposite the exhaust they are moved flush with the disc G by means of the rollers, so that they can pass through the abutment. Three claims are made.—No. 375788, dated 3rd January, 1888.

ELECTRIC CONDUCTOR.—*W. A. Barnes, Bridgeport, Connecticut.*—This method of forming the conductors applies to the construction of the circuits of electrical fire alarms. The wire is made of sections of fusible metal united together by short pieces of a metallic compound which is more easily melted than the longer parts. This slight irregularity in the fusibility of the circuit obviates any delay in the desired operation. The inventor makes two claims for this conductor.—No. 378078, dated 21st February, 1888.

ELECTROLYSING COPPER.—*E. S. Hayden, Waterbury, Connecticut.*—In order to purify copper, and free it from foreign and debasing matter, the inventor makes use of an electrolytic bath. The usual anode and cathode are placed at some distance apart, and the copper plates are rolled up and suspended in the solution. They are not connected with either electrode, but are only in contact with the solution. The liquid is kept circulated in order to accelerate the action of the current. Three claims are made.—No. 377487, dated 7th February, 1888.

CLEANING TOOTHED FEED ROLLS.—*H. Tindell, Harrison, New Jersey.*—Each end of the main cylinder is formed with a cam groove which has several undulations, and a stud playing in the groove is fixed on a forked plate which embraces the shaft of the cylinder. The outer ends of the forked plates are pivoted to links which in their turn are pivoted to the shaft of the feed roller. These links carry a cleaning plate, which is vibrated by the cams and pins, in order to clean the teeth of the feed roller. The inventor claims the combination of the links and cams which give the cleaning plate its motion for the purpose described.—No. 378739, dated 28th February, 1888.

ALUMINIUM.—*J. S. Howard, Springfield, Massachusetts, and F. M. Hill, Brooklyn.*—The aluminium ores are first boiled in muriatic acid. The resulting product is charged into a lime lined crucible together with a certain amount of Spanish white. When the temperature has been raised considerably, the mixture is covered with chloride of tin or chloride of sodium, and the whole subjected to a smelting temperature of 1000°F. The resulting alloy is afterwards melted in lead or bismuth; the aluminium then comes off free, and is subsequently purified by exposure to heat upon a bed of porous material. Three claims are made.—No. 378136, dated 21st February, 1888.

The full specifications of the British and United States patents, and the Official Journals of the German Patent Office, from which the above abstracts have been compiled, and the Official Journal of the United States Patent Office, may be seen by subscribers and clients at the Reading Room, Manchester Office of INDUSTRIES, *where also Patent Indexes from* A.D. 1617 *may be consulted. Copies of the British specifications may be obtained on application to* H. READER LACK, ESQ., *Comptroller-General, Patent Office, Southampton Buildings, London, W.C. The published price must be remitted, together with a sum sufficient to cover postage, which may be reckoned at ½d. for every* 10*d. or fraction of* 10*d. Remittances exceeding one shilling must be made by Post Office Order.*

INSTITUTION OF NAVAL ARCHITECTS.

The annual spring meeting of the Institution of Naval Architects was held in the hall of the Society of Arts on Wednesday, the 21st inst., and the two following days, the proceedings opening with the annual report of the Council, in which it was stated that the summer meetings held in Liverpool, Newcastle-on-Tyne, and Sunderland had proved very successful, and an invitation has been accepted from the President of the Institution of Engineers and Shipbuilders in Scotland, and from the Directors of the Clyde Steamship Owners' Association, and of the Sailing Ship Association, to visit Glasgow this summer. The last visit to the Clyde took place in the year 1877, and the prosperity of the Institution is said to date from that meeting. The Council having been informed that an attempt was being made to induce the Science and Art Department to remove and partly break up the Museum of Naval and Marine Engineering models at South Kensington, made representations in favour of allowing the collection to remain undisturbed. An official assurance was received that the Department did not desire to interfere with the existing arrangement, and that its hands would be strengthened by the action taken by the Institution. The number of members of the Institution shows a considerable increase, and the finances are in a satisfactory condition.

In moving the adoption of the report, Lord Ravensworth congratulated the Institution on its favourable nature. He regarded the approaching visit to Glasgow as especially appropriate, this year being the centenary of steam navigation. Referring to the general question of trade, Lord Ravensworth said that symptoms of improvement are noticeable, especially in our shipbuilding yards, but that it is vain to hope for a permanent improvement till peace is assured. During the year he had been impressed with the overwhelming importance of the question of the national defences, which had received a great impulse by the speeches of the Commander-in-Chief at the Newcastle meeting of the Institution. The question was still further brought into prominence by Lord Armstrong's speech on the Address, and by the report of the Committee of Inquiry into plans for the defence of our naval and mercantile ports. The Committee consisted of nine members, of which only two belonged to the services—an admiral and a general—and the charge could not be made that the seven civilians were prejudiced in favour of the expenditure of funds whether necessary or not. The gist of the report is that, upon the weakness of our present position, the witnesses were unanimous, and that the necessary works should be carried out without delay. The vote for this purpose of £3,000,000 during the next three years was regarded as inadequate. The importance of this question to the members of the Institution was insisted upon, as their property and works are situated in inadequately defended ports, and their ships are imperilled by the weakness of the coaling stations. The question involves four distinct issues, viz., the additional strength of the ports at home, of our coaling stations, of our colonial ports, and the necessity of keeping open the ocean routes upon which our food supply is dependent; but his Lordship regarded the first as of paramount importance. He next dealt with the question of the maintenance of our maritime supremacy, and declared that the only true policy is that now adopted—viz., to go ahead and keep there, be the cost what it may. Though the naval estimates for the present year are moderate, they provide for four new types of vessels. First are two armed cruisers, the "Blake" and "Blenheim," one being built at Chatham, and the other, fortunately, by contract. They are to have a speed of 22 knots at sea, and a displacement of 9000 tons. Their coal supply would enable them to run 15,000 knots at 10 knots an hour, and 3000 knots at 20 knots an hour. The second class is an entirely new one, and is represented by the "Vulcan," a torpedo depôt ship, which is to have a speed of 18 knots, and the duty of which will be to protect the small craft. The third class is that of unprotected sharp shooters, or torpedo gunboats, as they are termed, which are to have a speed of 21 knots. The last type consists of powerful sloops like the "Buzzard," and represented by the "Beagle" and the "Basilisk." They have a displacement of 1150 tons, 14½ knots speed, and twin screws, and their function is to act as police in distant seas. Turning from the navy to the merchant service, Lord Ravensworth said that in matters of construction the latter has shown even greater advance, as instanced by the "Oceana," the sister ship of the "Arcadia." Fortunately, these have satisfied the Admiralty requirements, and have been placed on the list of the naval reserve. The recently launched vessels, the "City of New York" (see *Industries*, Vol. IV., page 270) and "City of Paris," built for the re-constituted Inman and International Line, are also worthy of note. Their great peculiarity is in the minute sub-division of the hull, and there are no doors to the bulkheads, so that such an accident as that which occurred to the "Oregon" is prevented. Their displacement is 10,500 tons, and their speed at sea 20 knots an hour. During the past year there has appeared the report of the Committee of Inquiry into loss of life at sea. All the experts examined were unanimous about the marked improvement in all classes of ships. Mr. Dale, the chairman of the Liverpool Underwriters' Association—a body which controls annually £200,000,000 of insurance—said in his evidence that premiums are steadily becoming lower, and that they are now less than at any previous time. Mr. Glover put in a table to show that the reduction is general in all classes of ships, and Mr. Martell, of Lloyd's Register, has shown that the number of ships of the higher class is constantly rising in proportion to that of the lower. Mr. William Denny has testified to the improvement in cargo ships, and Lord Ravensworth's own observations fully confirm his evidence. Mr. Martell has given the following statistics on the subject:—

	Average in 1883.	Average in 1888.
Size	1500 to 2000 tons	3000 to 3500
Nominal h.p.	140	200
Speed	9 knots	10 knots

In discussing the causes of the progress, credit was given to the energy of the owners, the vigilance of Lloyd's, and a large share to the Institution of Naval Architects and kindred societies, as owing to the discussions of technical questions at their meetings improvements are well advertised and remedies constantly suggested for defects. Probably still more important is the influence of merchant ships being admitted as naval auxiliaries, which stimulates both the navy and the merchant service. Now that the Admiralty watches the building of all ships intended to be added to the reserve list, this factor has become especially important.

Our space only allows of our giving abstracts of the papers and of the discussion on them. As the first three papers on the programme dealt with allied matters they were read in succession, and the discussion on all three was taken together.

The first paper was by Mr. W. John, on

American Warship Design.

Though the United States Government has not gone to any great length in building up an ironclad fleet, yet during the past few years efforts in this direction have been made. In August, 1886, the Secretary of the United States Navy, Mr. W. C. Whitney, advertised for designs for a steel armoured battle ship and armoured cruiser. Mr. John, who was at that time general manager of the Barrow Shipbuilding Company, entered the competition and gained the 15,000 dollar prize for the battle ship. As he has been repeatedly asked for further details, he thought the following particulars would be of interest. The dimensions of the vessel are as follow: Length, between perpendiculars, 290ft.; breadth, 64ft. 1in.; depth, 39ft. 8in.; mean draught of water, 22ft. 6in.; displacement at 22ft. 6in. draught when fully equipped and with 500 tons of coal, 6300 tons.

The cruiser proposed was of a totally different type. The author much preferred a water line belt to internal protection, as the latter would give a background for bursting shell against, and thus yards of the thin side in the region of the water line might be ripped off, and both speed and stability be seriously affected. The belt in this ship is of 12in. steel faced armour, and is 2ft. above water amidships, and 4ft. 6in. below at the constructor's load water line. With an additional 450 tons of coal in the bunkers between decks the draught would be 14in. more. The main battery is of two 12-inch breechloaders placed in turrets in echelon, and six 6-inch breechloaders; the secondary armament consists of four 6-pounder Hotchkiss rapid-fire guns, six 3-pounder and two 1-pounder, eight Hotchkiss revolving cannon, four of 47mm. and four of 37mm., and four Gatling guns. Six torpedo tubes were stipulated, one in the bow, one in the stern, and two on each side. Four electric search lights were provided. The ship is built on the cellular double bottom principle, the double bottom extending under the engines and magazines for 158ft. There is a protective deck 3in. thick extending over the top of the armour belt and sloping down forward and aft at the forward end to the point of the ram, 10ft. below water. The bulkheads are of 6in. steel faced armour. The armour belt is backed up with 6in. of teak, two thicknesses of 25lb. plating, rigid framing and girders. The communications from the conning tower for navigating the vessel are protected by an armoured tube 3in. thick, and the hoists from the magazines by 6in. armour. In regard to the range of fire, the 12-inch guns are so placed that both command a fore and aft fire, a complete broadside range on one side, and a range of 40° for the forward gun and 70° for the after one on the other side. Of the 6-inch guns, two are arranged as bow and stern chasers, and four on sponsons on the main deck. The smaller guns are placed on the main deck, and some in the tops. Two second class torpedo boats are provided for, and sufficient boats to carry the crew, including a steam pinnace and a steam cutter, each mounting a 3-pounder Hotchkiss rapid-firing gun. In conclusion, the fighting qualities of the ship were summed up as follow: She has a speed of 17 knots in fighting trim. If she engages an enemy, her full battery of heavy guns, as well as three out of her six 6-inch guns and most of her secondary armament, will be available either when bow on, when chasing, or when running away; but if the enemy is one of the internally protected cruisers she will be liable to be raked fore and aft by shot, and especially by shell If the ships engage in an artillery duel, avoiding both ram and torpedo, this battle ship would have full play on her broadside for both her 12-inch guns, four out of her 6-inch guns, and most of her secondary battery. Hence the author maintained that for single action fighting, there is a great advantage in having the main guns echeloned and placed so high that their fire fore and aft cannot be interfered with by forecastles or poops, especially if the heavy broadside concentration can be maintained at the same time.

The next paper read was by Captain C. C. P. Fitzgerald, R.N., on

Unarmoured Water Lines in Warships.

The author commenced by explaining that the object of his paper was to call attention to the greater probability of one of our modern battle ships being sunk by many small wounds below the water line, rather than by a torpedo, the ram, or by what Sir E. J. Reed has called one of "the earthquake projectiles of modern warfare." Our experience of the sinking of ironclads is very meagre, including only the loss of the "Re d'Italia" by ramming, and of one or two small ironclads in the American Civil War. Nevertheless, the opinion is gaining ground that in the future more ships will be sunk in naval engagements than in the past. Sir N. Barnaby has told us that one of his main principles in design was so to construct vessels that they could not be disabled or destroyed by one blow; but even if this end has been attained, it will be but small consolation to a crew to know that having avoided the one heavy blow, they are slowly sinking, or are preparing to "turn turtle," from a cause against which they are quite powerless. The one blow theory catches the imagination more than the series of smaller wounds; yet it is the latter which will probably be more effective in the long run. Captain Fitzgerald ridiculed the "end on" theory of attack represented by such ships as the "Nelson" and "Northampton," as the system could not be applied in practice unless the enemy were so accommodating as always to run away. Besides this extreme case of the danger due to the designing of ships with one marked and distinctive feature, there is the more serious one, that in order to secure speed, coal endurance, and immunity from destruction on the "one blow" theory, many ships have been left with large areas of their water lines unprotected by armour, and the danger, moreover, has been greatly accentuated of late by the development of quick-firing guns. To avoid this, the French are adopting a preparation of cocoa nut fibre, called cellulose, as a lining to the unarmoured parts of their warships. The intention is to exclude water if pierced, and their new cruiser the "Dupuy de Lome" is expected to be practically unsinkable, owing to this lining. The author had experimented in this connection with india-rubber, and found that a 2·2in. projectile could be fired through an 1½in. plate without leaving any hole through which water could pass. At his suggestion, the Admiralty had caused other experiments to be made, and had declared the system to be a failure; but the author objected that it had not had a fair trial, and regretted that he had not been informed either as to the time or nature of the tests till after they had been made. A company has recently been floated to manufacture a patent composition known as "woodite," which is said to serve the same purpose. Without expressing any definite opinion as to the relative merits of these water excluding materials, the author insisted upon the necessity for experiment, as our already overloaded citadel ships cannot sustain any additional armour, and, therefore, the destructive effects of quick-firing guns on their exposed ends may lead to serious national disaster.

The third paper read was by Captain Hubert Grenfell, R.N., on

The Development of Modern Weapons, considered in relation to the Designs of Warships.

The author introduced his paper by insisting upon the necessity of unity of design in warships, to secure unity of action, a factor of great importance to success in battle. Early in the century the ultimate object in naval tactics was to get broadside to broadside, and trust to superiority of metal and endurance; but the introduction of steam, armour, heavy guns, torpedoes, &c., has entirely destroyed any such dominant idea, except with those who believe that the naval tactics of the future will be based on the exclusive use of one weapon, such as the torpedo or the ram. A definite pronouncement on the part of naval officers as to the mode in which naval actions should be fought is obviously necessary, to enable the naval architect to design ships so as to answer all requirements.

Digitized by Google

The author's paper was an effort to do this, by discussing the relative value of the various factors that influence ship designs. Mr. White was quoted, to show the almost absolute agreement amongst naval authorities on the importance of high speed in all classes of vessels. Hence it may be inferred that a similar agreement on other points is not unattainable. In regard to the construction of the largest class of ships, which it was understood the Admiralty had determined to discontinue, Captain Grenfell pointed out that this was only because we had sufficient for our needs, and as Italy still prefers them, and France is about to complete the once abandoned "Brennus" and "Charles Martel," the heavy ironclad seems to be still regarded as the most efficient implement in naval warfare. Guns capable of piercing 3ft. of iron plate were declared to be far superior, in proportion to the armour opposed to them, than those of any previous period had been. Moreover, a marked increase in gun power has been gained by greater frequency of hitting; thus from the Elswick quick-fire gun—a weapon of good weight and penetrating power—three shots have been kept in the air at the same time. In regard to torpedoes, the case of the Harvey and spar torpedoes was quoted, as illustrating the possibility of arriving by proper analysis at the capabilities of a weapon without any practical experience. They were both discarded after adoption in the navy as too limited in range, and with too many chances of failure, though these objections were known at the time of their adoption. The ram, as Mr. White has pointed out, exercises very little influence on ship designs, while its use has fallen into the background since Admiral Colomb showed what a hair's breadth separates the case of ramming an adversary from being yourself rammed. Turning to the ships themselves, though the gun is accepted as the most influential factor, we have oscillated from the principle of distributing the main armament to that of concentrating it—as in the case of the "Victoria," with her two 110-ton guns in the centre of the vessel, to that of more numerous and smaller weapons distributed, as in the "Admiral" class. The author considers high speed a disadvantage to the efficient use of artillery, and, therefore, not rightly a tactical factor in artillery duels. It was also remarked that, in the "Admiral" class, the effort to cover the whole horizon with her guns much diminishes the amount of fire that can be concentrated upon one spot. Another question upon which a definite understanding is required, is whether mere weight of metal is to be preferred to frequency of fire in cruisers. Whether, in fact, a more numerous armament of quick-firing 30-pounders would not be more advantageous in such vessels than a few heavy 10-in. breech loading guns. In discussing the subject of torpedo cruisers, the author lamented the fact that, though the preponderating influence of the gun is fully accepted for large vessels, yet for small ones the torpedo is regarded as the "dominant idea." In accuracy of aim, instantaneousness of discharge, rapidity of flight, and number of rounds that can be carried, the flying "air torpedo" is far superior to its submarine brother, while, on the most favourable assumption, the effect of a fair torpedo hit can only be rated as equal to that of the gun projectile. This change of principle is especially to be regretted in "torpedo catchers," a class of vessels built to chase torpedo flotillas in rough weather, in which the speed of the latter would be reduced, while that of their pursuer would be comparatively uninfluenced. In such work a number of small calibre quick-firing guns would be much more efficient than the cumbrous set of torpedo tubes with which they are provided. In conclusion, it was contended that, in frequency of discharge, accuracy of aim, simplicity of construction, economy in working, greater range, and less liability to derangement, the gun is far and away superior to the torpedo; and, therefore, the tendency to supplant the more powerful weapon by the less powerful is to be deplored, and is a change that will not stand the test of experience.

The discussion on the preceding three papers was commenced by Sir Spencer Robinson, and several of the naval officers present also took part in it. Those of our readers who have on previous occasions attended meetings of the Naval Architects when similar papers were read, will not be surprised to learn that the discussion was remarkable chiefly for its discursiveness, and the wide difference of opinion expressed by the various speakers on such questions as the relative value of side armour, internal protection, the ram, guns, torpedoes, and other points upon which very little actual experience has as yet been obtained. We heard again the same arguments and statements of opinion which were put forward last year in discussing Mr. Biles' paper on "Internal Protection *versus* Armour Belts," and as this was reported at some length in our issue of 15th April, 1887, a very condensed account of the present discussion will be sufficient.

Admiral Sir Spencer Robinson, who congratulated Mr. John upon his success in the competition, drew attention to the fact that the designer was handicapped by the United States Government in being compelled to adopt dimensions which almost preclude the possibility of a good design. The thickness of armour for a vessel of such small displacement necessitated its concentration upon a limited area, leaving the remainder much exposed, so that if this ship heels over only a few degrees the top of the belt will be below the water line. He deplored the absence of any definite system in deciding on what lines our ships should be designed, and thought Capt. Grenfell's paper a step towards such a system.

Admiral Colomb was in absolute accord with Captain Grenfell, except when he said that a successful torpedo hit would not do more damage than a successful gun projectile. He did not rate the torpedo quite so low, though at the same time he did not consider that a single torpedo would be fatal. Some of our most experienced torpedo officers had assured him that they would not regard a ship disabled with less than three good torpedo hits. In regard to Mr. John's paper, he was interested to note that we are returning to the old theory of short ships with narrow belts. The battle ship under discussion is weak on the port bow and starboard quarter, and it is doubtful whether it is quite adapted to either of the two main modern formations, viz., echelon and broadside fighting stem to stern. He had no doubt that quick-firing guns were more to be feared than the huge projectiles; no part of the water line should therefore be without armour.

Mr. Biles regretted that Mr. John had gone over to the enemy in the matter of vertical armour belt, and inquired in what way this ship would have an advantage in a running fight over one internally protected. It mattered little whether a hole were blown in the side of the ship at the water line or 2ft. above it. The main question was, what was sacrificed for the armour belt, and he maintained that two 45-ton guns and 3 knots of speed had here been lost. The speaker next pointed out that till further experiments have been made on woodite, cellulose, &c., the proper remedy against quick-firing guns is greater sub-division of the hull.

Sir Nathaniel Barnaby defended the design of the "Nelson" and "Northampton." The "Ajax" and "Agamemnon," designed in 1876, are 8500-ton ships, with armour rising many feet above the water line; but now we have vessels 500 tons larger, or even as much as 13,250 tons in one case, without armour on the sides. The "Blake" and the "Blenheim" show that we must have large ships. He agreed with Captain Grenfell that quick-firing guns were necessary for torpedo catchers, and he had designed a series without torpedoes and with only such guns for service in the Baltic during the crisis with Russia.

Admiral Scott considered that single action fighting will be more important than column fighting; hence vessels should be made strong all round, and weak parts should not be left to be protected by consorts. He regarded Mr. John's ship more as an armoured cruiser than a battle ship, and thought that armoured cruisers were rendered still more necessary since the development of quick-firing guns.

Mr. White called attention to the fact that narrow belts had been adopted by common consent. The French adopted it, and placed their guns high above water, thus producing a type that would have been unquestionably fatal to our ships with their low guns. It must be remembered that we build our ships to fight, not our own, but those of foreigners, and hence our designs must have reference to the action of other countries. It was pointed out that when the "Admiral" class were designed, beginning with the "Collingwood" in 1880, quick-firing guns were already in use, and since then they have been steadily gaining power. He had seen 36-pounders that could be fired fourteen times a minute. A 100-pounder quick-firing gun has now been made, and the limit has not yet been reached.

Mr. Benjamin thought the great defect in Mr. John's ship was the mass of armour about the turrets, which would weigh at least 300 tons. It might have the supports shot away, and thus the stability of the whole ship would be ruined.

Mr. John, in reply, said he would have been glad to have carried the belt right round the ship, but could not do so, as he was bound by certain definite conditions. In reply to Sir N. Barnaby's remarks on the "Nelson" and "Northampton," he declared he would not have those ships as a gift, as, if fought at an oblique angle, a shot might carry away all the side guns and then enter into the end turret, which would form a recess where a shell could explode with a maximum of injury.

(To be continued.)

Dutch Industrial Statistics.—These statistics will henceforth be published by the Government, who have appointed two travelling inspectors, with the object of collecting and arranging them. They will go about from place to place, visiting all factories and workshops. The municipal and other local authorities have been instructed to give these inspectors all facilities and information.

ERECTION OF THE SUPERSTRUCTURE OF THE FORTH BRIDGE.*

Three years ago, in a paper dealing with the construction of the steel tubes, I stated that to the end of those tubes as they lay in the yard the skewbacks were being connected. Since that time the whole of the twelve skewbacks have been placed in position on their respective piers, and are now riveted up and completed.

The Steel Piers.—These piers form three groups, and the skewbacks in each are so placed, in relation to one another, as to represent a rectangle. In each of these groups there are four skewbacks. They carry the entire steel superstructure, consisting of the steel pier overhead and the cantilevers on each side of the pier. The skewbacks in each set are connected to one another by tubes and heavy lattice girders. The tubes run parallel to the centre line of the bridge, the lattice girders at right angles and diagonally to the same centre. The vertical columns (improperly so called) are 12ft. in diameter, and spring from the skewbacks. Each pair of these columns batters towards the centre of the bridge as they rise, being 120ft. apart at their base and 33ft. at the top. The box girders on the top of each set of columns form a rectangle, two sides of which form the top tension members, while the other two act as braced struts. In the sloping plane of the columns diagonal tubes 8ft. diam. are placed, which run from one side of the skewbacks to the top of the opposite vertical column. In the other, or vertical plane, the wind bracing and the supports for carrying the internal viaduct are placed. The viaduct extends, unsupported, from the one vertical plane to the other. Additional diagonal and longitudinal bracing girders, fixed in a horizontal plane at the crossings of the diagonal tubes, take up the various stresses at these points. These members may be said to complete a steel pier.

The Cantilevers.—Each of the cantilevers may be said to consist of two braced brackets, securely connected along their lower part by diagonal bracing, and fixed at various points. They approach each other as they recede from the pier, and batter towards one another as they approach the top. All members of each bracket lie in the same plane. The bottom or compression member of these brackets is built up of six straight bays, joined at an angle. As the bays near the point of the bracket they approach a horizontal position, till the last bay

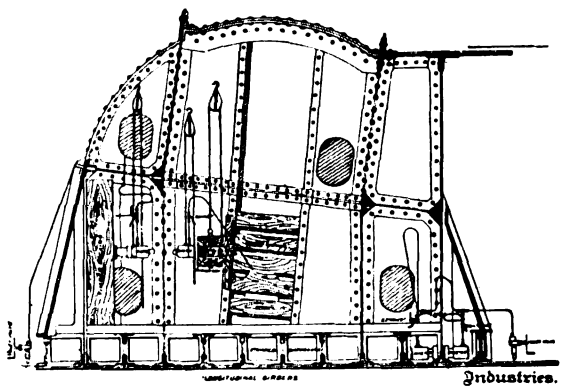

Fig. 1.

is actually horizontal. In section the first four bays are circular in form, in the fifth the shape gradually changes to the rectangular, and continues thus to the end of the sixth. The top or tension member is straight throughout, and, like the bottom member, divided into six bays, which are rectangular in form. The bracing in the brackets is of the double triangular type. The struts extend from the back of each bay in the bottom member to the front of the corresponding bay in the top member. The ties are the converse of this, the struts and ties therefore crossing each other. At the point of crossing a tie is fixed, which, extending to the bottom member, diminishes some stresses in that member due to dead weight. Between the struts box girder bracing is placed. Similar bracing is also fixed between the bottom members. Through these bracings the wind stresses of the cantilevers are transferred to the piers, and as this bracing, in conjunction with that between the struts, is utilised to transfer the wind stresses of the top member to the pier, no wind bracing between the top members is needed. The internal viaduct, insignificant in itself as compared with the cantilevers required for the carrying of it and its load, is supported by girders at the centre and ends of all the bays. After the cantilevers have been built, two gaps, of 350ft. each, will still remain. These will be closed up by a double parallel girder road. The girders will rest on the ends of the brackets, and lie towards one another with a batter similar to that in the piers. The skewbacks (Fig. 1) are the most complicated parts of the entire structure, the difficulties at this point arising out of the various angles at which the different parts lie in relation to one another and to the skewback. Each skewback may be looked upon as being either the starting point or the termination of five separate tubes and five distinct box girders. All these members are connected in such a manner to it as to transfer into or through the various parts of the skewback the stresses of each member. The skewbacks also act as the upper or sliding bed plates, on which some of the movements of the piers and cantilevers, due to expansion and contraction, take place. The sliding surface is the lowest course of several layers of steel plates, which form the base of the skewback. To the top of these plates a series of longitudinal girders are riveted, which are crossed at short intervals by one central and two smaller side diaphragms. Small stamped diaphragms are also placed between the longitudinal girders, immediately under the main ones. Between the centre and side diaphragms, and beyond the latter, are

* Paper recently read before the Institution of Engineers and Shipbuilders in Scotland by Mr. Andrew S. Biggart, C.E.

Digitized by Google

riveted four longitudinal lines of plates, and also a top plate, all of which merge into the horizontal and cantilever tubes at the opposite ends of the skewback. To the inner lines of the plates the sides of the two diagonal tubes are riveted. These also serve as part of the connection to the vertical column. Gusset plates and angles are principally used in effecting the connections of the girders to the skewbacks. The construction of the parts of the structure subjected to compression is very different from that of the parts subjected to tension, hence the dissimilarity between the bottom and top members. The cross section of the larger tubes consist of ten plates and ten H beams, running longitudinally, and as the plates overlap one another in this direction, they form five outer and five inner courses. Butting each other on end, they are there connected by double covers. The H beams are placed immediately over the laps of the plates, and are secured by the rivets passing through the longitudinal seams. At intervals of 8ft., stiffening circular diaphragms are introduced. In the smaller tubes, comprising the diagonal columns and struts of the cantilevers, the form is somewhat different, two flat sides being introduced to simplify the connections and crossings. These tubes consist of longitudinal plates and ties, varying in number with the size of the columns. The diameter of the largest tube adopted is 12ft., while the thickness of the plates employed is in some cases as much as 1¼in. In the cross section of the top members there are four booms, each consisting of ordinary flange and web plates, and in addition an extra horizontal web, for connecting the wind bracing. This, coupled with the vertical bracing, binds the whole into a stiff box form. The ties are similar to the top member in section, with the exception that there are no horizontal webs. In this case the horizontal wind bracing is secured to the flanges. The greater part of the wind bracing between the columns is of the same form as the ties, though in some cases it only consists of one angle iron at each corner of the box. The internal viaduct consists of two main girders, with the necessary cross girders, bracings, and roadway. The top booms of the main girders serve as troughs for two of the rails. The other rails are laid in troughs resting on the cross girders.

Erection of Steel Piers and Cantilevers.—The order in which the first portions of the steel superstructure should be erected was easily determined, but as the work proceeded many slight departures from the original plans were made. Some of these were caused by the exigencies which arose as the work proceeded, while others were dictated by experience. The first part of the work—immediately over the piers—was to place the lower bed plates in position. Following these came the skewbacks, which on being lowered were joined to the horizontal tubes and bracing girders. The latter were resting in position on trestles, having been built while the bed plates and skewbacks were being constructed. As soon as the skewbacks were ready to receive them, the vertical columns and diagonal tubes were, by means of cranes, built up to a height of about 50ft. Beyond that height rectangular platforms were built around the pier. The platform, weighing about 500 tons, was carried by the four vertical columns, and raised in stages of 16ft. at a time, by means of hydraulic rams placed within them. After each lift the four vertical columns, the four diagonal tubes, and as much of the wind bracing as convenient or necessary, were constructed. The work proceeded thus until the full height was reached. The top of the vertical columns, and the top members between the columns, were then erected. After that the erection of the top members and the first ties of the cantilevers was commenced. While the top members of the pier were being built, the internal viaduct over the pier, and in the first section of the cantilevers, was raised in small portions into position. After the bottom members were carried out a distance of about 150ft., and secured by temporary ties, platforms were built along their upper surface, and were afterwards used for the erection of the ties at the centre of bay one, strut one. These platforms were raised until they almost reached the crossing of the first ties and struts. Meanwhile, the first ties were carried from the top, down to, and across the struts. After they were secured a new base was formed for continuing the internal viaduct, the bottom and the top members, and the struts and ties, with the necessary bracing.

Platforms and Lifting Plant.—In structures like the Forth Bridge, where work requires to be executed at great heights, various kinds of staging, or false works, become a necessity. The first portions of the bridge were erected by ordinary

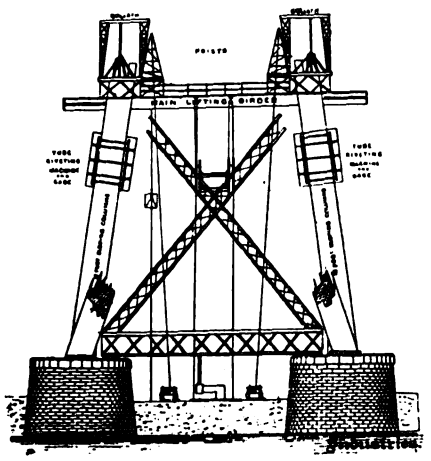

FIG. 2.

derrick cranes. Soon, however, the increasing height necessitated the use of platforms, on which cranes were placed. The platforms employed are of different kinds, and vary greatly in size. The largest is that presently in use on the top of the Inchgarvie main pier, its dimensions being 350ft. by 56ft. In striking contrast to this is the smallest, popularly

THE FORTH BRIDGE.

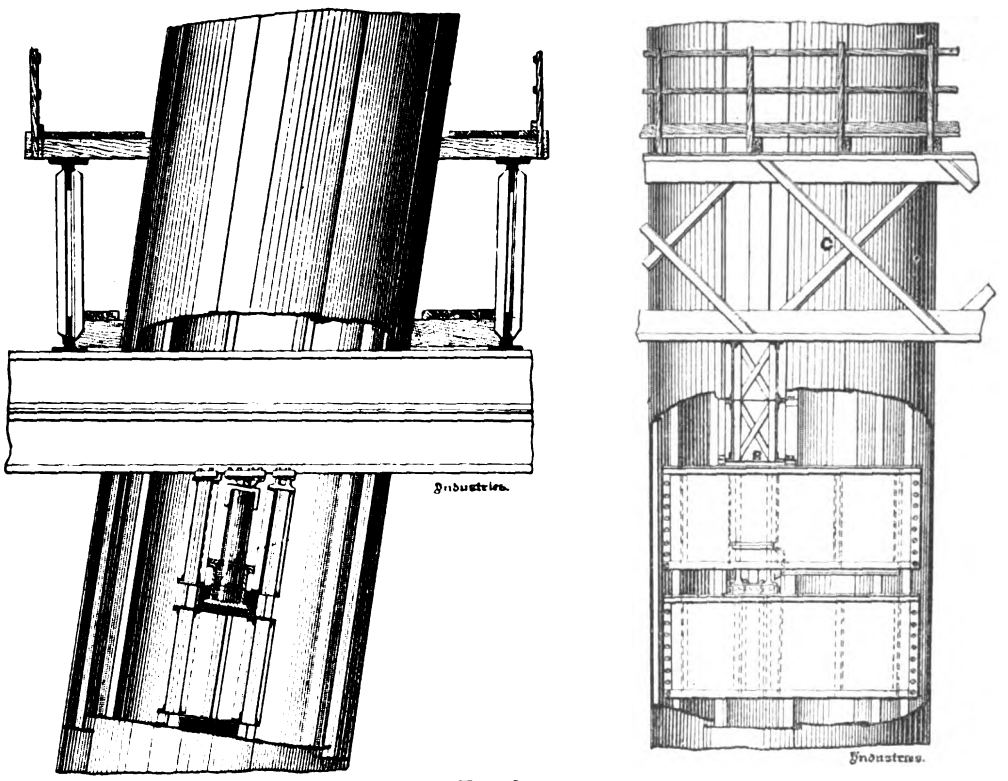

FIG. 3.

known as the "boatswain's chair." Between these two extremes the number and variety are almost innumerable. The platform with which the main piers were built surrounded in each case the entire pier. Those for the Fife and Queensferry sides of the river were similar in form and size, while that on Inchgarvie is larger, and has extra bearing and lifting columns placed in its centre. The Fife and Queensferry platforms (Figs. 2 and 4) consisted of two semi-independent platforms running parallel with the bridge, each surrounding the two vertical columns and

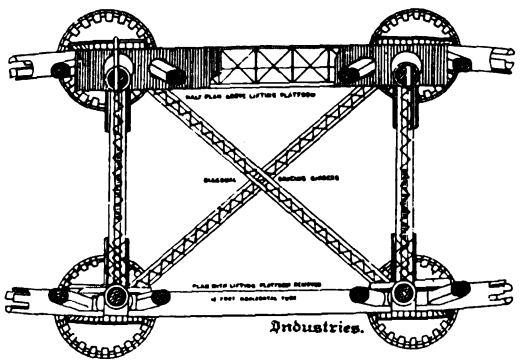

FIG. 4.

the two diagonal tubes on their respective sides. Each platform consisted of two parallel lattice girders, placed 18½ft. apart, with the necessary bracing, and were covered with planking, well holes being left to allow the columns to pass through. These half platforms rested on sliding blocks, placed on two strong box-shaped main lifting girders, which lay across the bridge and passed through the vertical columns. On the top of these box girders gangways were laid. These main lifting girders were in turn carried by short cross girders (see Fig. 3) within the vertical columns, pins passing through the girders and the permanent longitudinal H beams of the columns, to take up the weight. Similar cross girders were in like manner secured underneath these, and carried the hydraulic rams used for lifting the platform. The plant used in connection with these platforms was of a varied description, and comprised hoists for raising the material, cranes for building the columns, rivet heating furnaces, the large machines for riveting the vertical columns, and numerous other articles. So soon as a length of 16ft. had been added to the top of the columns above the platform, and one riveted underneath, the whole platform was raised another 16ft. This was effected by means of the hydraulic rams already referred to. On water being admitted to the rams, the weight of the main lifting girder was taken off the top cross girder, which allowed the pins to be withdrawn. This done, the main lifting girder and the cross girders were then raised 12in., and the pins re-inserted. One end of the platform now rested 1ft. higher than before. The action of the rams was reversed, and the lower cross girders were then raised the same height as the upper. The other end of the platform was similarly raised, and this alternate action was so continued till the full 16ft. lift was accomplished. During the operation of lifting, the two semi-platforms were moved towards each other to prevent them coming in contact with the battering columns as they rose. Before the pier reached its full height the bottom members of the cantilevers were commenced. As in previous instances, the first lengths were built by ordinary steam cranes. Soon, however, other means had to be adopted for carrying out the work. A cage (see Fig. 5) carried by the tube was secured round each of the members. It projected beyond the outermost point of the tube, and served as a platform whereon the men worked. A hydraulic crane was employed to put the material in position. It travelled along the whole length of the top of the cage, and could be turned completely round by means of hydraulic gear, in addition to raising and lowering the load. The cage is rectangular in shape, and consists of duplicate sections in 8ft. lengths, all of which are interchangeable. The cage is held in position by struts and ties, which extend from its corners to rings encircling the tube. As the work advances the sections are transferred from the back to the front of the cage. The hydraulic crane (see Fig. 5) used is of a peculiar design. It consists of two side travelling carriages, connected together by cross girders, on the latter of which are secured the connections necessary for carrying the jib and working the crane. The movements of the crane along the

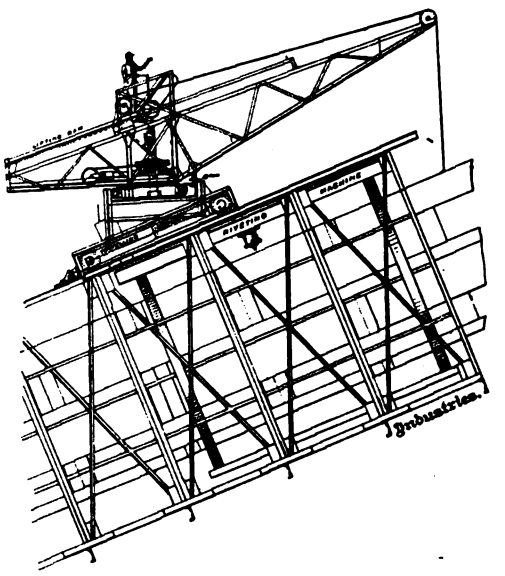

FIG. 5.

top of the cage are controlled by a ram on each of the side carriages. The raising of the load is effected by a single ram lying along the top of the jib. To the plunger of the ram a pulley is attached, and round it and the pulley on the jib point a rope is made to pass. This arrangement enables the load to be lifted a distance equal to twice the stroke of the ram. All the rams are made of wrought iron tubing, and castings are connected to the ends of the tubes for the fixtures and stuffing boxes. Steel wire ropes are employed to lift the load and slew the crane. For the building of the first section of the cantilevers, platforms (see Fig. 6) similar, though smaller, to those used in the case of the piers, were employed. They were built immediately over the bottom members, raised to a level position, and then lifted in stages till they reached a height about

Digitized by Google

THE FORTH BRIDGE.

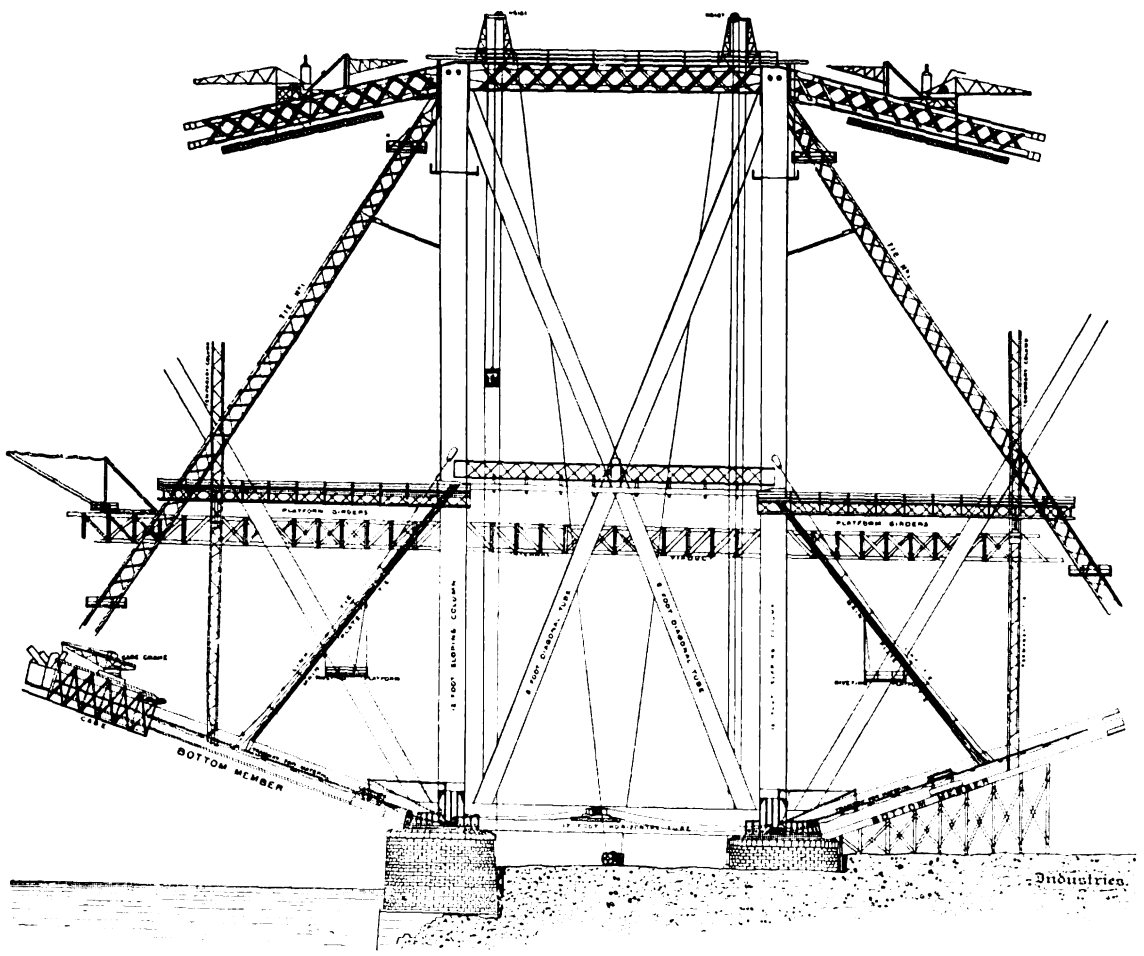

FIG. 6.

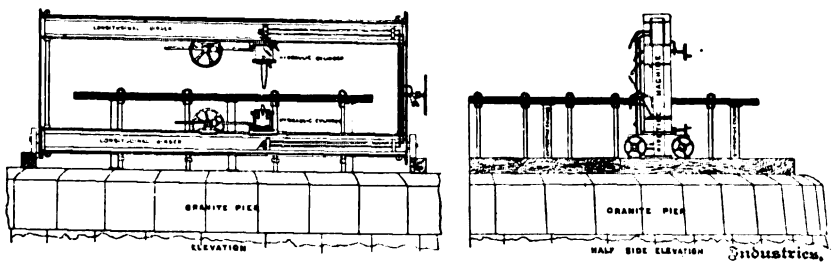

FIG. 7.

200ft. above high water. The raising was effected by means of hydraulic rams placed at each end of the platform. Those at the pier end were fixed to a projecting girder, secured to the vertical columns. Ties, or hangers, extended down to the platforms from these rams. Provision was made for the removal of the ties as the platforms were raised. The outer ends of the platforms were raised by rams, within the ties, which extended from the crossing of tie one and strut one to the bottom members in the middle of the bay. To the main lifting girders, extending across the bridge and carrying the platforms, these rams were fixed. Underneath the rams, and also on the opposite side of the ties, cross girders were secured by steel pins. In the erection of the top members and the upper parts of the cantilevers plant of peculiar construction has been adopted (Figs. 9 and 10). The plant rests on the upper surface of the top members, and consists of a sliding frame work of steel, from which a large platform is suspended. On the top of this frame work there are two cranes, one of which is actuated by steam and the other by hydraulic power. The former projects over the frame work towards the point of the cantilever, while the latter points in an opposite direction. The principal part of the work is done by the steam crane, as it is employed to build the webs of the top members, and also the upper half of the ties and struts. The hydraulic crane, on the other hand, is employed in placing the flanges of the top member in position, and afterwards in the riveting of the same. The steel frame work is composed of two main girders, lying across the two top members, and several cross girders. It is level on the top, and varies in depth and shape, so as to have a direct bearing on the respective sliding blocks fixed to the members. The steam crane is placed immediately over the top of the main girders, and has a jib 35ft. long, capable of being slewed 115 degrees on each side of the centre line of the bridge. The hydraulic crane rests on a platform projecting from the main framing. This platform is 76ft. long and 45ft. wide, and is secured to the frame work by braced angles. Its length is such that it almost extends as far as the points of the steam and hydraulic cranes, and in width is a little greater than the top members. It is made up of four longitudinal girders covered with timber, a hole in the front end being left for the material to pass through. When a length has been finished in front of the crane, the whole arrangement is moved forward to a position suitable for proceeding with the next length. The steam crane just referred to also places in position part of the material of the first ties and struts, and small stages are employed for work on these members. That for tie one (Fig. 6) consists of a timber scaffold, suspended by wire ropes from a beam lying across the upper booms of the tie. As the tie is gradually built downwards the scaffold is lowered by tackle. The stage for strut one is a steel cage surrounding the tube, and having two timber platforms, which are placed at different heights. It is secured to the tube by brackets, fixed at intervals, and is lifted by the steam crane on the top members. This cage is required only for the top half of strut one, as the lower part has been already built from the platforms used in the erection of the first section of bay one. Flexible steel wire ropes have been used in the lifting plant with good results. Accidents which occurred when chains and Manilla ropes were employed, have now entirely disappeared. During the erection, a large number of temporary ties and struts were employed for the purpose of keeping some of the members in position while unconnected, or enabling them to carry more temporary material. In the piers, both the vertical columns and diagonal tubes had, at several points, to be kept apart by struts, while the diagonal tubes had also to be tied to each other before they reached the top. The bottom members are now supported by temporary ties, which extend to the vertical columns. In these diagonal ties, the stress produced, for each bottom member, is about 500 tons. Although large platforms had been adopted in the beginning, smaller ones now take their place, as they are more easily managed. The reasons for employing these large platforms to build the piers, were principally a regard to the safety and convenience of the men at work. They enabled them to handle a large quantity of material, not only with speed, but attended by little danger to themselves. Large platforms are now not of the same value in the carrying out of the work, because cranes are already placed on the top of the bridge, which, without difficulty, can place material in position at a point 300ft. below themselves. By the introduction of light scaffoldings, only a few temporary ties are required to carry the permanent members.

Riveting Plant.—The hydraulic plant provided for closing as many as possible of the rivets in the bridge is, according to the work to be done, of a varied description. It may be divided into the following three types: 1st, the ordinary Arrol patent grab machine; 2nd, direct acting riveters, using pressures up to 3 tons per square inch; 3rd, special girder machines, for such work as the tubes and large flat surfaces. The first type mentioned does not call for special comment. The second type, or the direct acting riveters, using such a high pressure, is, however, we believe, novel. The riveter consists of a steel cylinder about 7in. long, provided with a solid piston having a cup leather at the back end. Two cylinders are used together, one acting as the holder-on, while the other is employed to close the rivets. Into each cylinder a pipe is screwed, which provides for the ingress and egress of the water, and at this point also the exhaust is regulated. The high pressure water is controlled by a valve on the pressure pipe at a point further back, and from where a convenient connection can be led to both cylinders. These riveters were originally designed and employed for riveting up the longitudinal girders and diaphragms in the skewbacks. Some of the spaces in which they had to work were only 2ft. 6in. long by 15in. high by 15in. broad, and access to this small space was still further reduced at the top by a 4in. angle all round. The method of application was to place one riveter on each side of the work. To each of these the water was led by a copper pipe from the regulating valve. A spring check valve was introduced into the pipe leading to the closing riveter, for the purpose of keeping back the water until the holding-on riveter had pushed the rivet home. When inserting a hot rivet, the holding-on riveter was moved out of position. After being replaced the water was turned on, when the riveter immediately pushed the rivet home, and held it firmly there. The other now came into play and formed the rivet head. A point requiring careful attention was the timber backing, on which the riveters had to take up their thrust. This was equally essential for both the speed and the quality of the work. Within the skewbacks it was no uncommon thing for a squad to close one hundred rivets per day, shifting during that time all the copper pipes and connections from cell to cell as they moved along. Although designed primarily for the riveting of the skewbacks, the application of these riveters has not been confined solely to them, but they have been usefully employed on other parts of the structure. Thus the heaviest rivets in the top connections of the vertical columns were almost all closed by them. In this case one of these riveters was used within the junction, while without an ordinary ram of about equal power was secured to a slide on a box girder. This girder, moreover, could be moved along the face of two other girders, thus giving the ram complete command over a large surface. The working pressure in this ram was 1000lb. per square inch, and in the small cylinder 3 tons per square inch. With this combined machine 150 rivets, from 8in. to 9in. long, could be closed per day. Before leaving the subject of high pressure riveters it may be interesting to consider the means adopted for raising the pressure of the water to almost 7000lb. per square inch. The most efficient means to gain this end is a pressure multiplier. This machine (Fig. 8) was constructed almost entirely out of ordinary plant. The principle was to employ a large ram, with a small pressure, for exerting an increased pressure by an attached small ram, the increase being proportional to the difference of the areas. This was effected by securing an 11in. ram to the one end of a frame, while at the other end of the same frame a 4¼in. cylinder was fixed. On the first ram a cylinder was placed, and attached to it was a small ram which acted as a plunger to the small cylinder. Water at a pressure of 1000lb. per square inch was led into the cylinder on the large ram, and as this power was transmitted to the small ram it gave a correspondingly greater pressure on the small cylinder. As the large cylinder moved backward and forward, it reversed

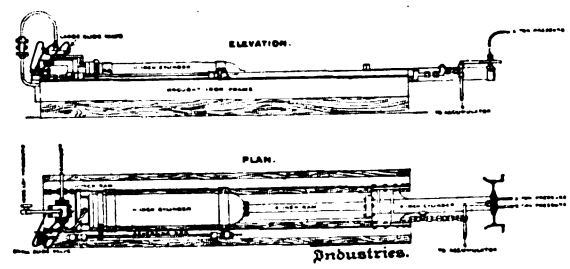

FIG. 8.

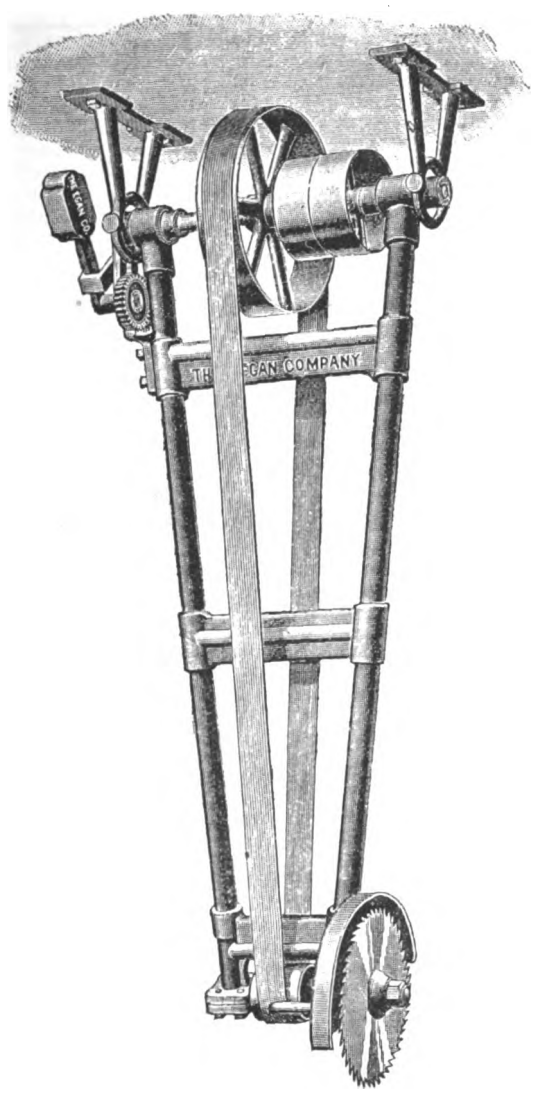
a small hydraulic slide valve which served to actuate the larger valve that regulated the water entering or leaving the low pressure ram. Besides this form of multiplier there are also portable ones. They are on the same principle as the large ones; but instead of being automatic in their action, they are worked by hand. The high pressure water pipes are made of wrought iron, and have flanges of the same material screwed and riveted on to their ends. The third type of riveting machines employed is of an entirely new pattern. Here also two rams are used. If required for such work as riveting the circular tubes, one of the rams is supported on a longitudinal girder outside of the tubes, while the other is held by a girder inside. These rams move on slides, and are capable of being raised or lowered by a small hydraulic jack. On the outside girder a compound slide is arranged to facilitate the adjustment of the die; but on the inside girder other means serve the same end. The outer longitudinal girder is, by slides at the top and bottom, secured to ring girders encircling the tube, and is traversed round the former by hydraulic jacks. Within the tube, and opposite these ring girders, are two diaphragms carried on brackets fixed to the longitudinal H beams of the tube. Each diaphragm has a centre socket or step, within which the points of the inside longitudinal girder are free to revolve. By gearing commanded from the platform on which the men are at work, this revolving motion is imparted to the girder, and through it to the ram. Working platforms are secured to both the outside and inside rams, and are raised or lowered along with them. The inside ram, being in most cases far removed from the rivet head, a special die has to be used. The machines when used for riveting the columns of the main pier were suspended



Digitized by Google

from the platform and raised along with it. On the main pier six hundred to eight hundred rivets were closed in a day with the machine just described. The machines used for the diagonal tubes were the same in principle as the above. The outside girders and inside diaphragms were, however, different. These had a double D form, being thus similar to the tube. This was to permit of their traversing the longitudinal girders at a distance parallel from the tube, and with the rams always pointing in the right direction. In the case of the outer girder this was effected in a manner similar to that adopted in the large machines, while the inner girder followed a race on the diaphragm. These various movements were obtained by small hydraulic rams. The machines were raised and lowered by tackle secured to the tubes, and were quite independent of the movements of the platform. For the riveting of large surfaces of flat plates, such as the bed plates (see Fig. 7) under the main pier, the principle adopted was the same as that for the large tubes—viz., two longitudinal girders, one on each side of the work, both provided with a ram for closing the rivets. The girders were secured at the ends by the plates. These also served as part of the carriage on which the machine was moved along as the work advanced.

Oil Heated Rivet Furnaces—As a full illustrated description of the oil furnaces used at the Forth Bridge for heating rivets was given by us a short time ago (see *Industries*, Vol. III., page 618), we need only refer our readers to this description.

SWING CUTTING OFF SAW.

A NEW swing cutting off saw is being made by the Egan Company, of Cincinnati, Ohio, of which we give an illustration herewith, reproduced from the *Railroad Gazette* of New York. The frame consists of wrought iron pipes with cast iron braces, and is suspended in

turned sleeve boxes, which are fixed in the brackets by which the whole machine is bolted to the ceiling. For clearness of illustration these sleeve boxes are omitted in our engraving. The counter shaft, with fast and loose pulley and driving pulley for the saw, is supported in the head of the frame and in line with the sleeve boxes, so that the frame may swing freely without affecting the driving belt. On one side of the frame is fixed a segmental rack, gearing into a pinion which raises a balance weight when the frame is brought up to the cut, and automatically swings the frame back when the cut is finished. The makers claim that by this method of balancing the frame, the speed of work is increased; whilst through the suspension in special sleeve boxes the shaft is protected from bending strains.

BRICKS AND BRICK MAKING.

AN interesting paper was recently read by Mr. William Johnson, of Leeds, before the Inventors' Institute, on the above subject. The principal improvements described by the author were as follow: (1) Process for manufacture of bricks from weak clays which are largely impregnated with lime; (2) the manufacture of fire bricks by machinery; (3) a new process for making a strong engineering and highly finished facing brick; (4) a process for the manufacture of sand faced bricks; (5) the utilisation of slate waste in the manufacture of bricks and other goods; (6) a substitute for the existing arrangement of brick making plants in Staffordshire.

Many clays which are used in the manufacture of ordinary bricks contain so much lime that the results obtained are far from satisfactory. The attention of the author was first drawn to improvements in the production of bricks from this weak clay by an engineer in Dublin. In several parts of Ireland the superficial clay contains from 20 to 30 per cent. of lime. On crushing this material, mixing it with water, tempering it, and subjecting it to heat, it was found by this engineer that the lime became silicated, and formed a flux which caused the whole to become one hard and strong conglomerate body, capable of withstanding a great strain. After several experiments, which were performed by the author with a view of producing this article in an economical manner, a machine was perfected which will turn out sound, strong bricks from the weak clay at a cost of 5s. per 1000. This character of clay is invariably of a soft and plastic nature, and must be first dried before it can be reduced to powder. For this purpose the author adopted a revolving cylinder 27ft. long by 5ft. in diameter. This is subjected to a temperature of from 700° to 1000°, which is produced by gas. The clay is brought up from the clay hole in the ordinary way by hoisting, tipped into a hopper, in which rotates a winged valve, forming a series of pockets which, as they come into position, are filled with clay, and each in turn discharges its load into the revolving cylinder, and the clay thus begins its traverse through the whole length of the cylinder, taking about thirty minutes to accomplish the journey. During all this time it is being subjected to the heat of the cylinder, the moisture thus being completely expelled. The thoroughly dry clay is then delivered at the lower end of the cylinder by a shoot into a perforated edge runner grinding mill, whence it is elevated into a revolving sieve. The fine powder drops through the sieve into a hopper, and the coarse is returned again to the grinding mill to be re-crushed. The powdered clay then runs in a constant stream into a double shafted and differential mixer, where the necessary water is added; then into the brick making machine and steam lever press, and the bricks, as they are discharged, are placed upon a bogie and taken direct to the kiln.

Another new departure in which the author has achieved success, is in the manufacture of fire bricks by machinery. There has always been strong prejudice against machine made bricks intended for refractory purposes. This has arisen from repeated failures, the bricks made having been either too loosely bound together or too densely formed. If the former, they were too friable and porous; if the latter, the contraction in cooling caused them to crack and break to pieces. The author stated that it was possible to produce by machinery a brick superior for resisting heat to the hand made brick. The necessary plant is simple and requires little power. It consists of an ordinary edge runner grinding mill, in which the clay is crushed; thence it is elevated into a differential double shafted mixer, where the water required is added; thence it drops into a hopper of the brick making and pressing machine, containing double moulds, making two bricks at once, which machine is both self feeding and delivering. The clay is fed into the hopper of the machine in a damp and granulated state. At the bottom of the hopper is a bottomless box, which is filled with clay, and travels over the two moulds, which are sunk below the surface of the table. The charger passes over them, empties its load of clay, and remains over them while a heavy pressing head drops with its own weight upon the body of clay in the charger, and insures the moulds being properly filled. This head is then withdrawn, and allows the charger to return again under the hopper for a fresh load of clay, during which time the pressing head drops a second time with its own weight upon the already charged moulds, and rests there to allow two further powerful pressings to be given to the bricks in the moulds. The head is then raised, and the bricks being automatically lifted out of the moulds level with the table are pushed away by the returning charger, to be placed by the attendant boy on to a bogie, and taken direct to the kiln without any shedding or drying. Examining the bricks thus made when burnt, it is difficult to distinguish them from the best hand made fire bricks.

The production of bricks from the waste of slate quarries has hitherto proved a failure; several modifications of the plant employed have been suggested by the author, with the effect of considerably improving the manufacture of bricks from this material. The fine even surface and the firm character of these bricks, and the perfect form in which they can be moulded, are such that they would no doubt largely, if not altogether supersede what are called rubber bricks, which, when ready for use, are worth probably not less than £10 per thousand, whereas these could be placed in the market at £5, and which price would insure a most handsome profit to the makers. They would also be preferred where resistance to great weight was required, and for hydraulic work, on account of their density and their non-absorbent character. They would also be suitable as adamantine paviours, invert blocks for main sewers, and for many other purposes. One great advantage in this material is that it is waste, and is already got to hand, and therefore to owners of quarries all royalty and cost of getting are saved.

The writer of the paper also described some useful improvements in the manufacture of facing bricks and sand faced bricks.

INTERNATIONAL TARIFF CONFERENCE.—An international conference, consisting of seventy-two members, is being held in Vienna, under the presidency of M. Lambermont, on the subject of Custom House tariffs, the object being to translate the tariffs into French, English, German, and Spanish.

FOREIGN INDUSTRIES.

(From our own Correspondents.)

PARIS, 27TH MARCH, 1888.

THE IRON MARKET.—The situation appears to be growing desperate for the Paris merchants, who cannot agree among themselves. The Syndical Chamber, which was designed as a bond of union between them, is in a fair way of becoming disorganised. The consequences are a drop of 4s. a ton in bars and joists, and the prospect of unstable markets for some time to come. This question of the merchants apart, all circumstances at present are favourable to the revival of trade. We are entering upon the season of spring, the building of the Exhibition structures is in full swing, the building trade is unusually active, and large orders from the Panama Canal Company are on hand for execution. The demand for old rails steadily increases, the price being very firm at £3. 4s. The latest reports from the chief centre of industry are encouraging. The revival makes steady progress, particularly in cast iron goods, the prices of which are constantly rising. It is rumoured that the Société des Hauts-Fourneaux, of Pont-à-Mousson, have obtained through the Comptoir d'Escompte an order for about 550 miles of 8in. pipes for the conveyance of petroleum from the wells of Baku to the Black Sea. If this rumour, which seems to be well founded, prove true, we may expect a considerable advance in prices in the course of the current week. Business in finished iron and steel continues on the whole fairly animated, and prices are everywhere firmly maintained. The foreign trade shows a tendency to expand in finished iron goods. The exports in the first two months of the year amounted to 5506 tons of pig iron, against 6290 tons in the corresponding period of last year; to 5663 tons of finished iron and wire, against 3503 tons; and to 2750 tons of steel goods, against 9353 tons. The falling off is in steel rails. The imports in the same time were 20,360 tons of pig iron, against 19,454 tons; 4208 tons of finished iron and wire, against 5508 tons; and 1483 tons of steel goods, against 2041 tons last year.

THE METAL MARKET.—The metal market exhibits symptoms of weakness. Copper has receded £2 a ton, and there are abundant indications of a continued relapse. The "ring" of speculators who have taken this metal under their control, will no doubt keep the market in a state of constant fluctuation; but they cannot prevent the decline of prices on the whole. Tin is weak, particularly English tin. Holland has ceased to buy on the Paris market. Stocks here are sufficiently abundant to enable consumers to press for concessions in prices. Excepting Straits, all kinds have lost this week £2 a ton. Lead shows symptoms of weakness. Spelter maintains its price, but the demand is by no means strong.

THE FOREIGN WORKMEN QUESTION.—This question continues to disturb the industrial world. The agitation is chiefly among the working classes, who seem resolved to take vigorous action in the matter. A few weeks ago a deputation from the working men of Paris waited upon the Deputies of the Seine, to urge upon them the necessity of excluding foreigners from all Government contracts. Last week an important meeting of workmen was held at Marseilles, at which the following resolutions were unanimously passed: (1) That foreign workmen should be excluded from all national and commercial workshops. (2) That they should be excluded also from the workshops of all companies and firms who execute State orders. (3) That all private persons or public companies who employ foreigners in their service should be taxed. (4) That the proportion of foreigners should never be greater than one-tenth of the total number of hands employed. (5) That a heavy fine should be inflicted upon all who infringe these rules. It was further resolved to call the attention of the Government to the "disastrous situation to which the German competition has brought our commerce."

BERLIN, 26TH MARCH, 1888.

THE IRON MARKET.—Close upon the action of the rolled iron syndicate, which, as reported in my last letter, has raised the base price 2s. 6d., follows a similar step taken by the makers of profile iron, who, at a meeting in Frankfort-on-the-Main, have decided to raise prices 2s. a ton. In Upper Silesia the condition of the market is not only firm, but may be characterised as rising, especially as regards crude iron. This is partly due to the heavy orders for forward delivery, and partly because the discrepancy between the prices of crude and finished iron becomes more and more noticeable. It seems highly probable that good foundry pig will in the coming week not be obtainable under 57s. or 58s. per ton, whilst for inferior brands 56s. will have to be paid. Forge pig is also tending upwards, the probable limit within the next few weeks being from 50s. to 54s., according to quality. Plate makers are well employed, showing that considerable activity exists in boiler shops and engineering works generally. In the syndicated districts bar iron sells at 140s., profile iron at 155s., and boiler plates from 160s. to 165s. The building trade promises to become very active this year, and considerable quantities of building iron will be required. For this class of rolled iron the quotations vary from 111s. to 123s. according to the district, and the increase of 2s. 6d. per ton will be partly shared by dealers in the shape of a better discount. Steel wire for export is quoted at 103s. to 105s., and for the home market at 118s. The export trade is languishing.

MACHINE EMBROIDERY.—In Saxony the long winter has somewhat delayed the placing of orders for the summer requirements of embroidered goods; but, nevertheless, this branch of business is at present in a more satisfactory position than at the same period last year. Common embroideries and embroidered flounces are not much asked for since the fashion has changed, and the fine cambric Nansoe and silk embroidery have taken their place. Cotton weavers are well employed with gauze linings, Marly, &c., whilst English curtains are in fair request; bleachers and finishers are, consequently, also well employed.

JUTE.—At a recent meeting of the Society of German jute manufacturers, it was decided to prolong the union scale of prices till the 1st of July next, provided that the members of the Society agree to abstain from any extension of their business. One large works would, however, only agree to this on the understanding that the weekly working time of both spinners and weavers should be limited to sixty hours. The discussion of this proposal was adjourned till the next meeting of the Society.

TRADE WITH ITALY.—The new treaty of commerce with Italy affords advantages which must tend to promote the trade in cotton and woollen manufactured goods with that country. Already there are signs of the new life infused into the textile industries by the prospect here opened up. Manufacturers are preparing to meet a heavy demand which, it is confidently expected, will result from the establishing of favourable commercial relations in these branches of trade between Italy and Germany. There is good ground in the past for this expectation. Since the opening of the St. Gothard Railway, German intercourse with Italy has rapidly grown, and the advance is nowhere more strikingly seen than in the exports of cotton and woollen piece goods, in which we come into competition with English manufacturers. Last year the exports amounted to 23,434cwt., against 17,594cwt. in 1886 for cotton piece goods, and to 10,366cwt., against 7529cwt. for cotton yarns. The increase in woollen goods for the same period was from 20,434cwt. to 24,220cwt. for woollen fabrics, while yarns declined from 2202cwt. to 1308cwt.

HOPS.—During the past week about 700 bales of hops have been sold, but at rather low prices. Merchants are glad to dispose of their stocks, and are quite open to make concessions. The buyers are partly commission agents and partly exporters. The stocks of hops of good qualities are not very considerable, but large quantities of inferior qualities are in hand at Nürnberg, which is the principal market.

VIENNA, 26TH MARCH, 1888.

THE IRON MARKET.—No change of any importance has as yet taken place in the iron market; but the situation in some branches has been still further depressed by the heavy floods in Hungary. Crude iron remains dull; but some improvement is noticeable in rolled iron, especially for building purposes. In those districts which have not been affected by floods building operations are now being actively pushed forward. There are many public and private buildings in Hungary now in course of construction, and a brisk demand for rolled iron is setting in. There is also a good demand for plates and tinned sheets, but hardware is dull. Engineering works are fairly well employed. Negotiations have for some time been in progress with a view to forming a syndicate of wire nail makers. Some forty representatives of the trade met on the 14th and 16th instant, and agreed on the more important clauses. At these meetings the difference of opinion was so slight that there seems little doubt but that the syndicate will shortly be established. The necessity for a syndicate lies mainly in the low prices and heavy discounts which are usual in the nail trade. Some fairly good orders have been booked for rails, sleepers, and axles.

TEXTILES.—Large transactions in cotton yarns are taking place, both buyers and sellers being eager to do business; but the prices for wool have a downward tendency. The commencement of the season in the Buda-Pesth market has not brought about any alteration in the situation. Business in silk is by no means active, and the war of tariffs between France and Italy has had no favourable influence on our trade. Linen goods remain in good request.

THE SUGAR TRADE.—The success of the syndicating of other trades has led to a sugar ring being formed here, which proposes to raise the price of sugar by 20 florins per ton. The total annual consumption in this country is about 250,000 tons, so that if the present movement proves successful, sugar manufacturers here will benefit to the extent of 5,000,000 florins per year, a sum equivalent to the export bounties received by them.

ELECTRIC TRAMWAY.—Some time ago I reported the inauguration of a short experimental electric tramway line from the Central Station along the Königsgasse and part of the Ringstrasse, the total length being 1·1 kilometres. The service on this line has now for some months been perfect. The generating dynamo is established in a shed near the railway station, and the current is supplied by means of a central channel and a pair of conductors, against which slide two contact shuttles. There are at present only two cars in use. These are of the same type as those on the Lichterfelder tramway near Berlin. The transmission of power from the motor spindle to the car axle is by steel wire spiral cords. The central channel is of masonry throughout, with cast iron chairs for the support of the conductors, and has two steel rails on the top, leaving a slot 1¼in. wide. Manholes are provided in several places to give access to the channel, and efficient provision is made for draining it. Messrs. Siemens and Halske, who have built this line, are now experimenting with various forms of contact shuttle. They have asked for a concession to extend the line the whole length of the Grosse Ringstrasse, now building, and they also made an offer to the town authorities to build, and equip with electric apparatus, several tramway lines which were originally projected for steam traction. In all cases they ask that the usual concession of forty years should be prolonged to fifty years, the extension of time being justified by the heavy initial outlay for the permanent way.

CARBONS FOR ARC LAMPS.—The manufacture of arc light carbons forms an industry of considerable magnitude, and the works of Herr Hardtmuth, in Döbling, are now turning out about 3500 metres of carbons daily. Some improvements have recently been made in the process of manufacture, under which the homogeneity and density of the carbons are increased. These refer more especially to cored carbons. As usual, the rod of plastic material issues from the press in the form of a tube, and after drying and baking, the carbons are steeped in a heavy hydrocarbon, by which the pores left after the first baking are filled. The carbons are again baked, and the core is then inserted under a pressure not much greater than that of the weight of the plastic mass forming the core. In connection with this factory is a well equipped electrical laboratory for the testing of arc lamps. There are dynamo machines by various makers, viz., Pöge, of Chemnitz; Kremenezky, Mayer, & Co., of Vienna; Krizik, of Prague; and Siemens and Halske (alternator). The reason for installing various dynamos is to be able to test any lamp which may be sent to the laboratory. There is also a spectroscope for determining the elements contained in the carbon from the spectrum of the arc, and the laboratory is equipped with the usual electrical measuring instruments and photometers. The work at this laboratory is done on a thoroughly scientific basis, and both lamps and carbons are tested so as to determine the best quality of carbon to be used for each type of lamp. At the forthcoming Jubilee Exhibition Hardtmuth carbons will be largely used for the arc lamps.

BRUSSELS, 27TH MARCH, 1888.

THE COAL MARKET.—Although the influence of the winter season on the coal market is near its end, all kinds of coal maintain their position, and an advance has taken place in small coal. The future prosperity of our coal industry is a question of cheap transport. This subject has been discussed at a meeting of the Union Syndicate of Brussels, at which Messrs. Sabatier and De Vergnies advocated the total suppression of all tolls, and expressed the opinion that a reduction of the rates of freight was necessary to enable our coal to meet the competition to which it is subject. A reduction of the North-Eastern rates to Longwy and Nancy has caused a considerable increase in the railway traffic, and further steps of a similar nature are required to facilitate the export trade. Forward sales of coke have been made for the last quarter of the year at 12s. per ton. It is, however, doubtful whether the iron market will admit of such high rates being paid, as the exports of rolled iron this year will probably be less than in 1887, and the manufacturers of finished iron are unable to pay the high price asked for pig if they do not obtain more for their goods. In the Mons district the market is very good. Household coal finds a ready sale, and there is a strong demand for industrial coal. The situation at Liège is also favourable.

THE METAL MARKET.—As far as prices and orders are concerned, the market is satisfactory; but the scarcity of raw material causes some uneasiness among manufacturers. The sales of old railway material which took place last week show a decided difference in the prices compared with the last. The following contracts have been obtained for rolling stock for the State railways: Lots, each of 50 10-ton trucks—Société Internationale, £4,370; Société Haine St. Pierre, £4,376; Baume & Marpent, £4,384; Société Franco-Belge, £4,390; and Chandronneries de Houdeng, £4,390. Lots, each of 50 10-ton coal trucks—Morlauwelz, £5,080; and Dyle & Bacalan, £5,120. Lots, each of 50 coke waggons—La Metallurgique, £6,480; and Malines, £6,520. Lot, of 35 coke waggons—Nicaise & Deleave, £4,550. Lot, of 35 large covered waggons—Société Franco-Belge, £4,676. Lot, of 30 covered waggons—M. Verhaegen, £4,032. The plate syndicate has officially adopted 120s. as the base price for No. 2 plates, and the rates are now as follow, delivered in Belgium and on the Terneuzen canal: No. 2 plates, 120s.; No. 3, 137s.; No. 4, 192s.; No. 5, 240s. Large plates: No. 2, 112s.; No. 3, 120s.; No. 4, 145s.; steel sheets, 140s. Owing to stocks being low, pig iron continues very firm, and the high rates are maintained. M. Cambier will put a second furnace into blast next month at La Louviere, and this will have some effect on the situation. The production of rolled iron during the present season will amount to about 500,000 tons. Calculating that on the total consumption there is about 10 per cent. of loss—580,000 tons of iron were required for last year's production of 532,108 tons of rolled iron. The imports of foreign forge pig amount to 40,000 tons per year. This leaves about 540,000 tons to be produced in Belgium. There are at present in blast twenty-two furnaces, turning out daily 1845 tons of forged pig. Deducting 10 per cent. loss, this makes a total production of about 600,000 tons. It is therefore expected that the re-lighting of another furnace will produce a

Digitized by Google

better balance between producers and consumers.—In the Charleroi district the works of Dyle-Bacalan and La Metallurgique are busy with rolling stock for the State railways and some narrow gauge lines, and with material for the Braine-le-Compte and Malines railway stations. There is a strong demand at Liège for pig, and prices are maintained, the Athus works quoting 38s. 5d., and Halanzy 40s. for No. 3.

Glass Works.—The foreign trade in glass during January, 1888 and 1887, was as follows, the figures for the latter year being given within brackets:—Imports: Window glass, £191 (£38); plate glass, £22 (£25); common glass ware, 222 tons (163 tons); ordinary glass ware, £2,500 (£2,328); fine glass ware, £46 (£37). Exports: Window glass, 5923 tons (5896 tons); plate glass, £19,942 (£10,283); common glass ware, 417 tons (93 tons); ordinary glass ware, 663 tons (835 tons); fine glass ware, 95 tons (40 tons). There are plenty of orders from the United States, but otherwise export trade is slack. Unfortunately, owing to the uniform prices established by the syndicate, most of the American orders have fallen into the hands of two or three of the large works, and smaller firms in consequence do not derive any benefit from the improved rates.

DÜSSELDORF, 26th March, 1888.

The Iron Market.—The iron market has changed but little in the past week. The greater part of the country is under snow, a circumstance unfavourable to the development of the spring trade. External influences have neutralised one another. Thus we have increased strength in England and weakness in Scotland. A languid market for finished iron and steel in Belgium, and renewed vigour in France. At the last meeting on the Siegen Iron Exchange business was active and prices were buoyant, sellers having apparently full confidence in the future. Spiegel pig for home consumption is in strong demand, but on foreign account few dealings take place. Contracts have been entered into sufficient to cover the next three or four months. The 10 to 12 per cent. manganese quality is still quoted at 59s. Forge pig is less inquired after. A few transactions for delivery in July and August have been recorded at 52s. Bessemer pig is in brisk demand at 54s. to 54s. 6d. Thomas pig remains unaltered at 45s. 6d. to 46s. Foundry pig is still much sought after. Business in finished iron and steel is on the whole fairly animated, but manufacturers complain of the high cost of the crude material. In present circumstances a further rise in finished iron seems impracticable. A journal has given the relative prices of German bars to Scotch pig iron warrants for each year since 1872. In the ten years ending with 1882 the ratio of bars to pig warrants was, on an average, 2·4. In the next five years, ending with 1887, the average was 2·5. The highest in the fifteen years period was 2·9, the lowest 1·6. At the present time the ratio is 3·3. This is a sufficient answer to those who maintain the opinion that prices are not abnormally high. There is more inquiry for bars; but joists are in feeble demand, the weather being unfavourable to building operations. For plates and hoops the market is active. Sheets are not much sought after, nor is there much life in the wire trade.

The German Export Trade.—At a meeting of the Union for the Protection of Industry in Rhineland and Westphalia, recently held here, the vitality of the export trade was made the subject of discussion. Figures were quoted to show that while the exports from England in 1887 compared favourably with those of the preceding year, the increase in the foreign trade of Germany was much greater. Thus, for cotton goods, the increase from England was 2 per cent., from Germany 25 per cent. Woollen goods increased 2 per cent. from England and 7 per cent. from Germany, and machines showed an increase of 10 per cent. from England and 80 per cent. from Germany.

LILLE, 27th March, 1888.

Textile Manufactures.—The wintry weather of the last week has had a retarding effect upon the course of trade in textile goods. Under ordinary conditions the spring trade begins to grow brisk in the fortnight immediately preceding Easter; but this year, with the greater part of the country under snow, the retail houses refrain from purchasing. The turnover in the linen goods trade has increased since last week, but it is considerably below that of the corresponding week of 1887. With the return of fair weather we may expect a rapid revival of business. In the Roubaix district the tone of affairs has improved, though the markets for woollen goods show no greater activity. It is, however, felt that we are on the eve of a revival. The present week, being that immediately preceding Easter, is likely to bring a great increase of business. Yarns are in slightly better demand, and spinners hope to obtain shortly more remunerative prices. South American wool has advanced fifteen centimes per kilo. Woollen cloth for men's wear is better situated than most other classes of goods, and weavers who make this a specialty have plenty of orders on hand. Hosiery, too, a branch of the woollen industry, which is rapidly growing in importance in the Tourcoing district, exhibits a fair amount of life. A report from Lyons describes the market as fairly active for silk goods. Many English buyers are on the spot, and these, as well as the agents of Paris houses, are purchasing freely. The goods most dealt in are Glacé, Moiré, and Pékin. The death of the Emperor of Germany occasioned a very heavy demand for crape.

Flax and Yarn Markets.—Home grown flax is still in good demand, and prices remain firm. There has been less buying in Russian, but prices have not given way. The situation is unaltered for yarns. The finer numbers are much sought after, at prices that tend upwards, while the middle numbers are comparatively neglected. Foreign and home orders are, however, sufficient to absorb the production, so that spinners are able to resist the efforts of buyers to obtain easier terms. Tow yarns are slightly weaker in price. A satisfactory amount of business has been done in jute yarns. Prices are very firm.

The Iron Market.—The market for iron has been less animated this week; but, as manufacturers have plenty of work in hand, these fluctuations attract but little notice. Doubtless the calm is in part due to the inclement weather. The strikes, which for some weeks past have disturbed the course of trade, have now come to an end. Prices are as follow: Merchant bars, £5. 4s.; joists, £4. 16s.; angles, £5. 12s.; common plates, £6. 8s.; boiler plates, £7. 6s.

The Sugar Trade.—The campaign of 1887-88 is now at an end, and the exact figures of the quantity of sugar produced are now known. The quantity of roots operated upon was 3,614,632 tons, against 4,873,755 last year, a diminution of 1,250,123 tons. The crude sugar produced amounted to 380,000 tons, against 472,000 tons last year, a decrease of 92,000 tons.

MADRID, 26th March, 1888.

Pig Iron.—The Viscaya Blast Furnace Company, of Bilbao, have now published their prices, which are about 12 per cent. under those obtained by the syndicate during the last twelve months. These rates are so low that some works will be unable to compete, and if the syndicate be not re-established, with prices on a more remunerative basis, it is difficult to see how these works can continue to produce.

Railways.—The shares of the railway between Bilbao and Durango are quoted at a premium of 100 per cent., which is in marked contrast with many of the other railways in this country, the shares of which stand at about half their original value. The difference is due to the way in which the schemes have been financed, and capital can be judiciously invested in Spanish railways if they be promoted in a proper manner. In the case of a concession for a line from Oviedo to Infiesto the whole of the necessary capital was immediately subscribed, as the business was in the hands of men whose names were a sufficient guarantee that the line would be constructed at a reasonable cost. It is probable that this line will be extended at a future period so as to pass from Oviedo to Bilbao through Llanes and Santander. Our railway lines have been much damaged by recent snowstorms, and in many cases they have been completely blocked. A bridge, near the coal basin of Mieres, was carried away a month ago, causing a total cessation of coal traffic; but communication was re-established last week.

NEW YORK, 17th March, 1888.

The Coal Market.—The anthracite coal trade remains dull, the supply exceeding the demand. Nearly all the miners have returned to work, and it looks as though the market would be greatly overstocked in a short time. At the conference to determine prices for the coming season, the following were adopted for anthracite: $3·75 per ton for fire burning broken, $4 for egg, and $4·25 for stove and chestnut, all f.o.b. The bituminous market is quiet, with but little inquiry. Prices, as fixed by the Seaboard Association, are $3·25 f.o.b. at South Amboy (New York), and $2·60 at Philadelphia and Baltimore. A number of European steamers are taking large cargoes of coal outward on account of scarcity of freight.

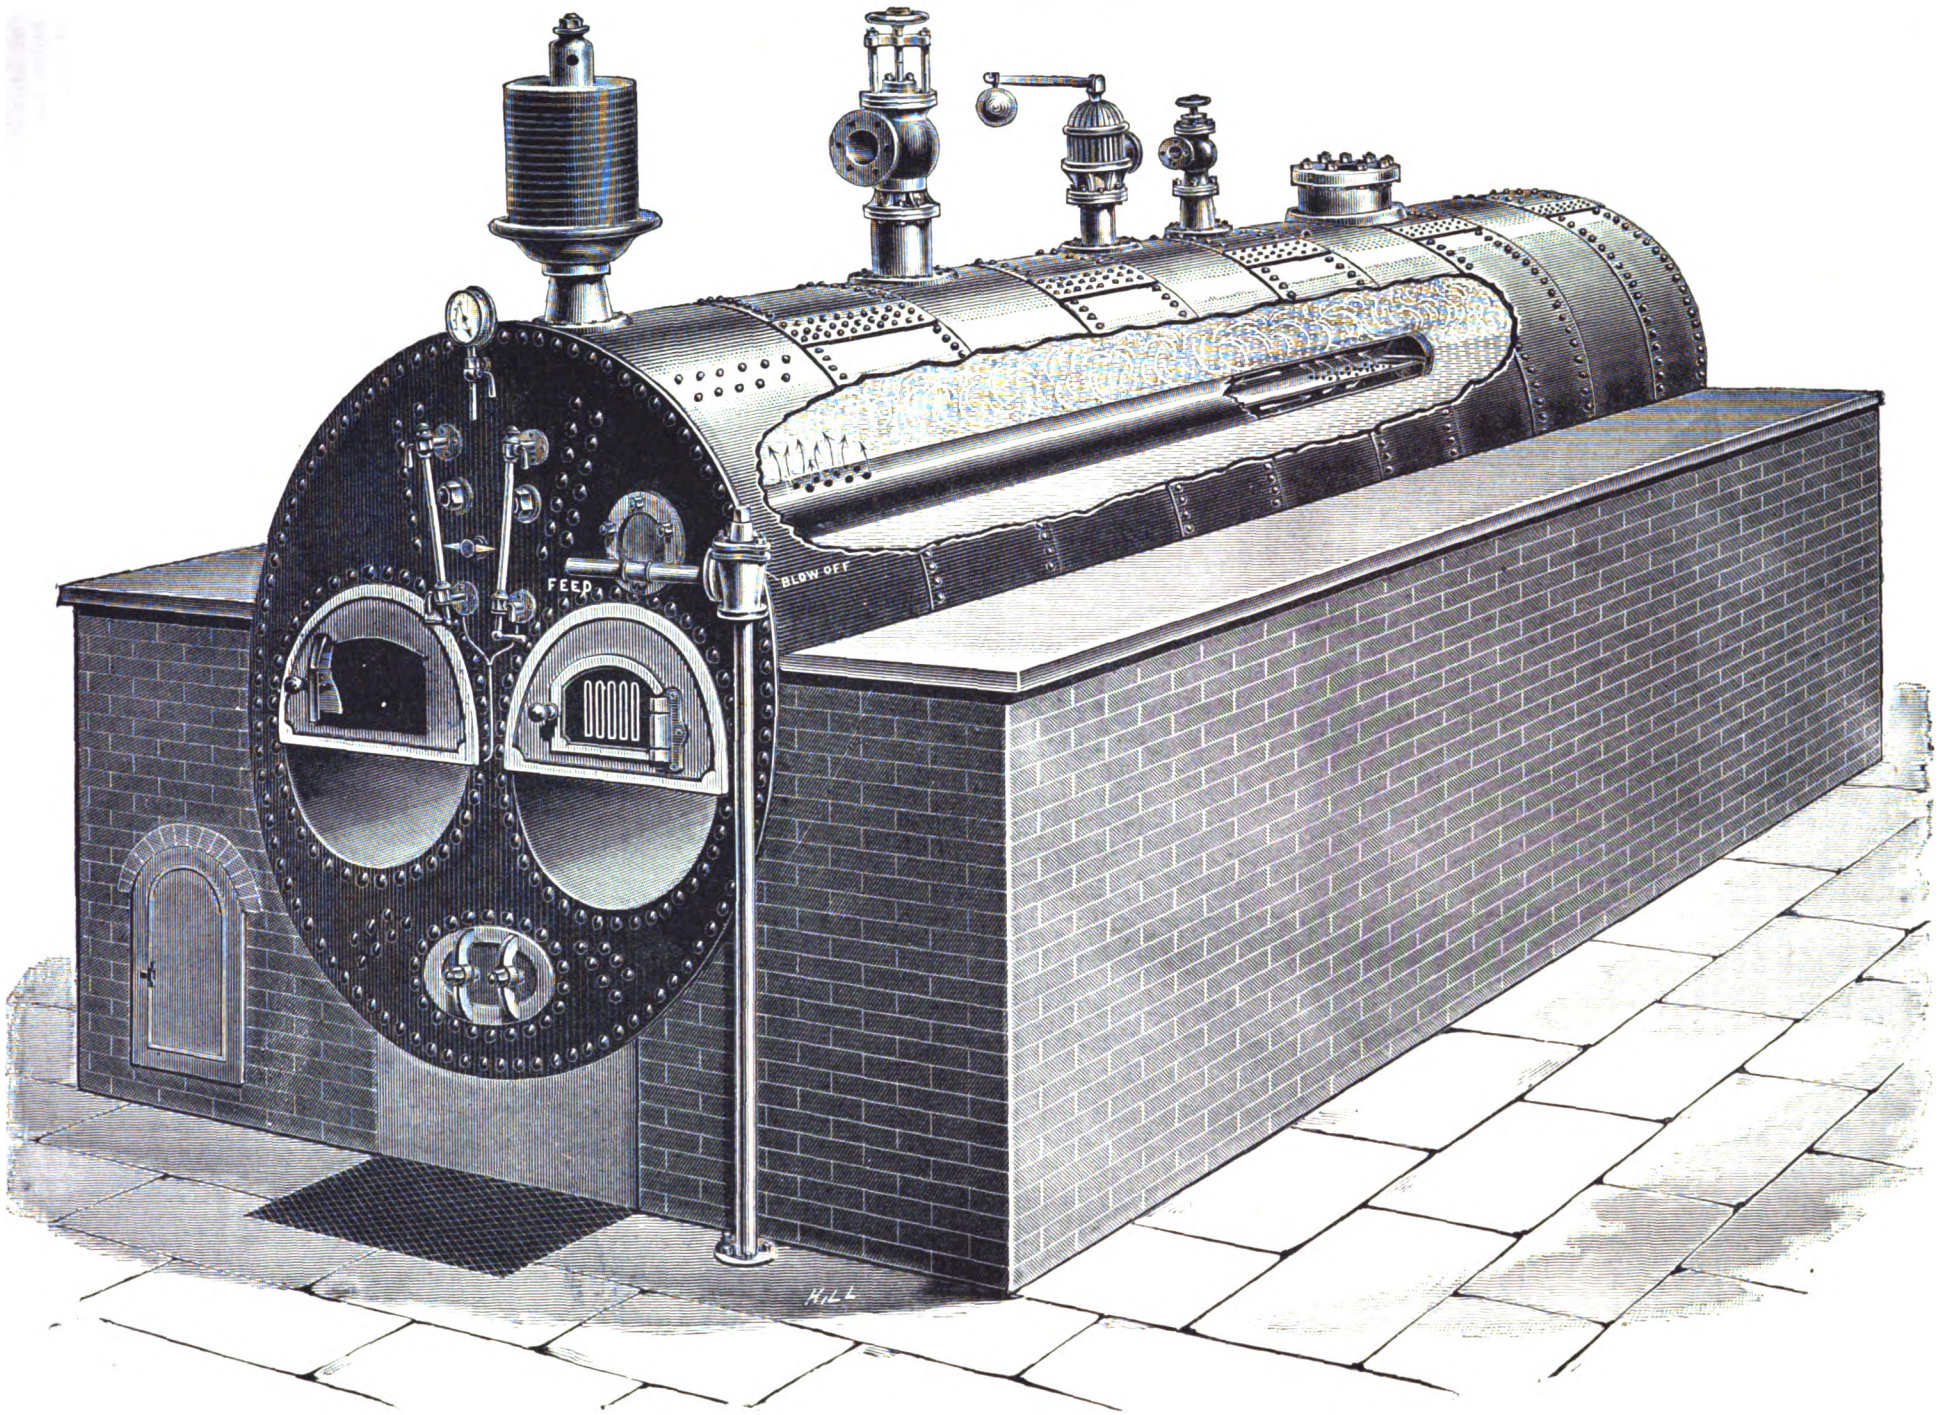
The Iron and Steel Markets.—The iron trade has again been dull this week. The pig market is practically unchanged. Makers of standard brands, whose stocks are low, fail to see either dulness or weakness; but those who have accumulated a lot of inferior brands or have new brands for sale, find the market very weak. There are moderate sales at old prices, and although some manufacturers are looking for a heavier demand, there seems to be little prospect of a decided change. As regards bar iron there has been a fair amount of business in specialties; but the general market is very dull. Some of the makers are willing to undersell the market; but as the price of bars is now nearly the lowest ever recorded, and considering the cost of the raw materials is the lowest ever known, a fall can hardly take place. Small lots command about 1·9 to 1·95 cents per lb. for best refined bars, and 2·1 to 2·2 for plates; but considerably better returns are given for anything like fair sized orders. The steel rail market is quiet, and prices are being maintained. Business will not be likely to improve as long as the tariff agitation continues. A reduction of $5 per ton duty would admit rails to the southern ports, such as Galveston, New Orleans, and Mobile, and would put the Pacific trade entirely in the hands of foreigners. The owners of the twelve steel rail mills in the United States have held a meeting to decide how the output for the coming year should be distributed. It is estimated that the demand will be but little over half what it was in 1887, and that prices will be lower. A leading coke operator states that inquiries for coke indicate that the steel rail mills will resume operations in a few weeks.

Electricity.—The current number of the *Electrical Review* of this city commences the thirteenth volume, and a new departure has been made by the addition of a coloured cover, the front page of which bears a bold design, which is free from all advertisements. The issue contains a number of interesting articles, is well illustrated and printed, and several improvements have been made in the arrangement of the letterpress.

The Metal Markets.—The copper market has been dull, but slightly higher. The total sales have amounted to 3,500,000lb., the greater part being for future delivery, at prices as high as 16·50 cents per lb. No more smoke is issuing from the Calumet and Hecla Mines, and the temperature is falling. The tin market has been quiet, about 160 tons having changed hands, the market closing at 35·80 cents to 35·95 cents per lb. The greater part of the dealings in lead during the last week have been speculative. Light sales for distant future delivery were made, evidently with the intention of impressing consumers with the idea that now is the time to buy. Spot sales were made at from 5·17½ cents to 5·20 cents, futures running as high as 5·35 cents per lb. for September.

Railroad Building.—The future of the iron trade is largely a matter of opinion, differences being due to guesses as to what railroad builders may do. Purchases of rails and material to date have been mainly for repairing or replacing equipment. The projected mileage for the next two years covers about 20,000 miles, that is, the mileage that is seriously intended to be built. Two years ago estimates were for 37,000 to 40,000 miles, of which 23,000 miles were actually built. The railroads will mainly be built to make land, mineral, and timber investments productive in the next five years, instead of for the traffic they may haul in the time. Short lines generally of from fifty to one hundred miles in length will be wanted, and most railway building will be of this character. The last report of the Railroad Commissioners of New York State gives some interesting data respecting accidents on New York railroads during 1886 and 1887. During 1886 there were 513 persons killed and 1138 injured, while in the last year the number had increased to 532 killed and 1260 injured. Attempts in every case were made to determine if possible where the blame for accidents should be laid, and an analysis of the tables in the report shows that the increase was not due to defective construction, rules, or discipline, but partly to unpreventable causes, and the greater part to the carelessness or misconduct of the parties injured. Although great improvements have been made in the last five years in the adoption of uniform signals and rules, and in the improvement of the construction of bridges, much remains to be done to make life safer.

PHILADELPHIA, 17th March, 1888.



Central Electric Light Station.—The Edison Electric Light Company of this city are erecting the largest station for lighting in this country. As this station is to supply the central portion of the city, the land on which it is built is very valuable; it was therefore necessary to limit the area to 70ft. by 100ft. In order to get the required space, the building is carried up 114ft. above the pavement, and is divided into six storeys. On the ground floor will be located twenty engines of 250 i.h.p. each. They are of the Armington-Sims type, running at 200 revolutions per minute. The foundation for the engines will be practically solid with the concrete foundation of the building. On the second floor will be forty dynamos of 1500 lights each, making the total capacity of the station 60,000 16-c.p. lamps. The dynamos will weigh about 7 tons each, and will run at a speed of 650 revolutions per minute. On the third floor will be the workshops, where wires and conduits are prepared for laying in the streets and making connections with houses. On this floor will also be located the two blast fans, driving 50,000 cub. ft. of air per minute into the furnaces. The products of combustion will be discharged by means of two shafts, 9ft. in diameter, and so built on either side of the house as to resemble huge bow windows starting from the third floor. On the fourth floor will be placed the boilers. Their rated capacity is 5000 h.p., and they are to be of the Abendroth & Root tubular pattern. The smoke will be discharged downwards into the flues on the third floor, and the ashes, which will fall into pyramidal ash pans, will be discharged into cans on the same floor. On the fifth floor there is storage capacity for 1000 tons of coal. The arrangements are such that on the first floor the coal waggons are driven on to scales. After being weighed the coal is discharged into shoots, delivering directly into elevators, which carry it to the fifth floor, where it is shot into the bins. Arrangements are made for delivering the coal directly in front of each boiler. On the sixth or top floor will be the general offices of the company. The distribution is to be on the three-wire system, and there are thirty-five mains leading out of this station. The company has already expended £40,000 for copper conductors, and eleven miles of street mains have been laid, leaving about twenty miles more to cover the district. This quantity will be laid during the coming summer. The station when finished will cost £200,000. Arrangements have already been entered into to furnish upwards of 10,000 lamps, and as the company intends furnishing power in any quantity that may be desired up to 100 h.p., there is no doubt but that the venture will be a financial success.

FEED WATER HEATER AND PURIFIER.

CONSTRUCTED BY MESSRS. CHARLES APPLEBY & Co., ENGINEERS, LONDON.

(For description see opposite page.)

Digitized by Google

FEED WATER HEATER AND PURIFIER.

In the annexed illustration of a Lancashire boiler, a part of the shell is removed to show the arrangement of an improved feed water heater and purifier which is being introduced by Messrs. Charles Appleby & Co., of 89, Cannon-street, E.C. The apparatus is singularly simple in construction, consisting of a horizontal wrought iron pipe which extends into the boiler at or near the water level. The ends of the pipe are closed by cast iron plugs, that at the front acting also as a flange for fixing to the front plate of the boiler. In the centre of the pipe runs a horizontal wrought iron diaphragm, held at the two ends in a slot in each casting, and being tightly fitted into the pipe throughout its length at the mid section, it cannot sag. In the far end of the diaphragm a series of holes are drilled, and at the top of the front part of the tube there is a second set of holes. The feed water is introduced by a T pipe into the lower half of the tube, and travels its full length, passing upwards through the holes in the end of the diaphragm and returning through the upper half, when it finally passes into the boiler through the holes in the top of the tube. By thus forcing the feed water to traverse twice the length of the tube, it is heated to a high temperature, and at the same time the heat causes the water to deposit its impurities before it reaches the boiler. The deposition is facilitated by the comparatively low velocity of flow through the tube. The impurities are thus retained in the tube, and can be blown out from time to time. The pipe delivering into the lower half of the purifier is in connection on one side with the main feed, and on the other side with the blow-off pipe, each branch being fitted with a valve. The valve for the feed is shown on the right in the engraving, the connection with the blow-off pipe being shown broken off. When it is desired to clean out the purifier, the feed valve is closed, and communication opened with the blow-off pipe. The flow is now reversed, steam and water rushing in at the holes in the top of the purifier, flowing along the part above the diaphragm to the extreme end, then through the holes in the diaphragm and back along the under side of the diaphragm to the front of the boiler, and thence to the blow-off pipe. Under this action, all sediment deposited on the diaphragm and the lower part of the purifier is scoured out.

On a recent visit to Messrs. Appleby & Co.'s works we saw two Lancashire boilers, one of which was fed with Thames water in the ordinary manner, whilst the other had been fitted with one of these purifiers a fortnight previously. The difference of the colour of the water in the two gauge glasses was most striking. In the boiler which was fed in the ordinary manner the water was thick and muddy, and the cocks in a dirty condition. In the other the water showed perfectly clear, and the cocks were all clean. This boiler, we were informed, had not been cleaned out for a fortnight before the fixing of the purifier, so that the latter had not only cleared the entering water of deposit, but had partially purified the water already in the boiler. The purifier tube in the boiler we inspected is 18ft. long, 6in. diam., and $\frac{3}{16}$in. thick, the wrought iron diaphragm being of the same thickness. The holes in the diaphragm and pipe were ten in number, and 1in. diam. From testimonials shown to us from America, where the apparatus has been fully tried, both in stationary and locomotive boilers, we learn that the apparatus causes considerable saving in fuel, and an almost absolute freedom from scale in the boilers to which it is affixed.

Notices of Meetings.

NEXT WEEK.

Royal Institution of Great Britain.—Monday, 2nd April, 5 p.m. General monthly meeting.

Architectural Association.—Friday, 6th April, 8 p.m. Members' soirée. Fifth sessional visit.

Geologists' Association.—Friday, 6th April, 8 p.m. Ordinary meeting.

Junior Engineering Society.—Friday, 6th April, 7-45 p.m. Paper to be read on "Steel Manufacture," by Mr. H. Smethurst.

Institution of Civil Engineers.—Friday, 6th April, 7-30 p.m. Students' meeting. Paper to be read on "Coke Making," by Mr. G. E. J. McMurtrie, Stud.Inst.C.E.

New Process for Casting Copper.—Stern Brothers, of Essen, have obtained a patent for a new process of casting copper, whereby any shape and dimensions may be produced free from defects. The process, which has been found to give perfectly satisfactory results, offers great advantages, inasmuch as castings may be used in the place of drawn and rolled pieces. As these castings may be obtained in any degree of hardness, the process is likely to be largely used in the manufacture of electrical apparatus.

CLYDE SHIPBUILDING FOR FEBRUARY, 1888.

The tonnage launched in February was exceptionally small, the vessels for which contracts were booked in the autumn being still on the stocks. New contracts booked during February have not been of any considerable importance. Messrs. John Reid & Co., Port Glasgow, have a contract for a vessel of 1000 tons. Wm. Simons & Co. are constructing a dredger for the Manchester Ship Canal Company. Messrs. Fleming & Ferguson have on the stocks a small steam yacht of 40 tons for Mr. Sholto Douglas. Besides these a number of yachts are being built by various firms. Among these is a vessel somewhat similar to the "Thistle," but composite instead of steel. This yacht will be built by Messrs. D. & W. Henderson & Co., who were also the builders of the "Thistle."

The following vessels were launched during the month: "Chasely," steel screw steamer, 450 tons gross measurement, built by Messrs. Murdoch & Murray, Port Glasgow; "Nil," twin screw hopper barge, 400 tons, engines 300 i.h.p., built by Messrs. Lobnitz & Co., Renfrew, for the Suez Canal Company; "Strathearn," steel screw steamer, 2814 tons, engines 250 h.p., built for Messrs. Burrell & Son by Messrs. Alex. Stephen & Sons; small wooden tug, 10 tons, screw, for towing purposes on the Ganges, built by Mr. Rodger, Port Glasgow.

" English Ingots	157	0	0	"	159	0	0

Messrs. Carrick & Brockbank, Manchester, report as follows:—

Copper.—Quotations for Chili very steady, but only a limited business has been done in ingots during the past week. Manufactured quiet, and quotations without change.

Tin.—Although quotations for Straits spot parcels keep firm at about £166 per ton, forward deliveries are obtainable upon a lower basis—say for May £135, and for June down to £125 per ton.

Lead.—We have no change to report.

Spelter is a little easier.

We understand that Messrs. Holden & Brooke, Limited, St. Simon's Works, Salford, Manchester, have secured the principal employés formerly engaged by Messrs. Sharp, Stewart, and Co. in their injector business. The latter firm on removing to Glasgow have, we understand, arranged to discontinue the manufacture of injectors, and Messrs. Holden & Brooke are now supplying duplicates of the Giffard, Atlas, Friedmann, and other patterns recently made by Messrs. Sharp, Stewart, & Co.

On Tuesday, the 27th inst., Her Majesty's ship "Nile" was successfully launched at Pembroke dockyard. The "Nile" is a sister ship to the "Trafalgar," and she measures 345ft. in length between perpendiculars, and 73ft. beam. Her load draught will be 27ft. forward and 28ft. aft, and her displacement 12,000 tons. The hull is built entirely of steel, and her total weight amounts to 4230 tons, exclusive of glacis plates and protective decks. Two sets of triple expansion engines indicating 12,000 h.p. will propel her at a rate of 16½ knots.

On Thursday, the 22nd inst., Mr. Henry Robertson, M.P., died at his residence, Pale Hall, Corwen, North Wales. Mr. Robertson was well known as a railway engineer and director of several railways, besides being the owner of extensive coal and iron works. He was the engineer of the Chester and Shrewsbury Railway, and constructed the viaduct of nineteen arches across the Dee. He was also one of the principal promoters of the railway now in progress from Birkenhead across the estuary of the Dee.

On Saturday, the 24th inst., Mr. Benjamin Piercy, M.Inst.C.E., died in his 62nd year. Mr. Piercy was well known as the pioneer of railways in North Wales, and as the engineer of the lines which now form the Cambrian system, and also of several railways in Wales and Shropshire. He also constructed the lines of the Royal Sardinian Railway Company, and was engineer-in-chief of the Vendee Railway in France, and of the railways and collieries of the Assam Railways and Trading Company in India. He was largely interested, with the late Mr. Henry Robertson, M.P., in the coal and steel industries of North Wales.

HOME INDUSTRIES.

MANCHESTER, 29TH MARCH, 1888.

THE COTTON TRADE.—During the past fortnight the fall in price of American cotton has become more marked; Middling Orleans now stands at 5⅜d per lb., which is a reduction of 1/16d. on the week. There can be no doubt that even the "bulls" are at last reluctantly compelled to admit that the size of the crop is larger than was estimated in November last. The trade helped to advance the price by free purchase early in the season, apparently because of an implicit belief in the *bonâ fides* of the American reports. It is perhaps a little premature, but it is quite safe, to predict that the autumn will again see a repetition of the same tactics, and in all probability with the same success. It is again proved that cautious buying is the best policy during the period when the first part of the crop is coming to hand, and it is hoped that spinners will take this view in the future. A similar fall has occurred in all ordinary spinnings, and the result is that spinners are little better off than they were. No sales of great magnitude have taken place, and there is a little anxiety among some spinners who are completing present contracts. At the same time there is evidence of business in the market if it can be transacted at the prices offered; but as sellers are still able, in most cases, to hold out against a reduction, sales are not effected. It appears likely that buyers will have to advance rather than that sellers will come to them. Silver is at present very weak, and the offers from the Eastern markets are made at lower rates in consequence. Cloth is weaker, and there is here an undoubted tendency to obtain orders even at reduced rates. For the moment the supply has overtaken the demand, and when the new manufacturing concerns which are in process of erection begin to work the pressure will be increased. There is some talk of a movement in North and North-East Lancashire for a reduction of wages, but at present no decided action has been taken. It is, however, certain that the margin which is now obtainable is very much narrowed, and the dividends of manufacturing establishments are likely to show a considerable decrease in the immediate future. On the whole, makers are still under contract, but in many cases these contracts are beginning to run out, and an era of lower prices seems inevitable.

RAILWAY ENTERPRISES.—The new line between Wigan and St. Helens was formally commenced last week, the contractors being Messrs. Pilling & Son, of Manchester. The line opens up several coal fields, and puts them in communication with the works of St. Helens and Liverpool. A direct line is projected between Burnley and Clitheroe. The line is only four miles long, and will thus save 10½ miles in distance. The company which has the matter in hand has a very strong directorate; the capital of the line is £168,000, and the engineers are Sir Douglas Fox, C.E., and Mr. G. H. Leane. The existing line of the Preston and Wyre Railway between Preston and Fleetwood is to be doubled. The contractor for this work is Mr. T. Riley, of Fleetwood. A much talked of line between Preston and Blackpool, running along the coast, is being begun, and will form a direct communication between Blackpool and the midland counties. The line is in connection with the West Lancashire Railway, and will be worked by the Cheshire Lines Committee.

THE SILK TRADE.—A meeting of the committee of the newly formed Silk Association, which was originated at the Manchester Exhibition, was held in Manchester a few days since. A code of rules was adopted, and the officers and committee appointed. It was determined to call a meeting of dyers and finishers, to consider what steps could be taken to improve this branch of the trade. A general meeting of the Association is to be called during the silk sales in London in July, and altogether the Association appears likely to be of great service in resuscitating the silk trade in the United Kingdom.

LONDON, 29TH MARCH, 1888.

THE MONEY MARKET.—The demand for money was considerable at the beginning of this week for the purposes of the Stock Exchange settlement, and the rates for loans hardened as compared with last week. Though there has been a fall in the Bank rate of a half per cent. since last settlement, the rates ruling this week were only about a quarter less than those charged a fortnight ago. Withdrawals of gold from the Bank, and the expectation that still more will follow if the course of exchange maintains its present tendency, have helped to give the harder tone to the market. The approach of the Easter holidays begins to tell upon the stock markets, for the Stock Exchange is always on the look out for an excuse, be it good or bad, for doing little business; but with the opening of the new account a better feeling is exhibited in nearly all departments. Investment business continues to run in an easy but steady current, and British Government securities remain strong. The foreign market is fairly good, though very susceptible to Continental rumours. Home railways have an upward tendency. There is also an appearance of the beginning of the long looked for improvement in American stocks, but this market is still most uncertain. The Budget this year is of special interest to the Stock Exchange, because a number of the new taxes affect it. The increase of the duty on contract notes puts a heavy tax upon every transaction. The taxation of the capital of new limited liability companies is a judicious step; and if the stamp duty on foreign securities can be thoroughly put into operation, it will be one of the most satisfactory and just features of any recent Budget.

COMPANIES.—The following new companies have been registered since our last report: Rockwell Silver Mines, Limited (New South Wales), with a capital of £175,000; Elandsfontein Gold Mining Company, Limited, with a capital of £150,000; Threlfall's Brewery Company, Limited, with a capital of £600,000; Tarapaca Water Works Company, Limited, with a capital of £40,000, to supply water to Iquique, Chili; the Gordon Diamond Company, Limited (South Africa), with a capital of £200,000; the Delta Metal Company, Limited, with a capital of £150,000; Hewitt Brothers, Limited, with a capital of £200,000, to carry on the business of brewers, at the Tower Brewery, Great Grimsby; the Patent Enamel Company, Limited, with a capital of £150,000; the Exeter Electric Light Company, Limited, with a capital of £20,000; the Callington United Mines, Limited, with a capital of £100,000; the Aboukir Company, Limited, with a capital of £300,000, to take over a concession granted by the Egyptian Government to reclaim Lake Aboukir; W. & R. Richards, Limited (brewers), with a capital of £11,000; the Moruya Gold and Silver Mining Company, Limited (New South Wales), with a capital of £85,000; the Springwell Brewery Company, Limited, with a capital of £150,000, to acquire the business carried on by Whitworth Brothers, Heckmondwike; Elk Mountain Gold and Silver Mining Company, Limited (Colorado), with a capital of £400,000; Waterloo Brewery Company, Limited, with a capital of £10,000, to carry on business at Oldham; the Fire Brigade Equipment, Limited, with a capital of £75,000, to acquire patents for fire escapes, and to manufacture such apparatus; G. P. Lee, Limited, with a capital of £25,000, to carry on a cabinet making business; the Hispania Tin Mining Company, Limited, with a capital of £175,000; the Guarino Hydraulic Gold Mines, Limited (Republic of Colombia), with a capital of £50,000; Dale Mills Company, Limited, with a capital of £12,000, to carry on the business of spinning, weaving, &c.; the Continental Pneumatic Tool Company, Limited, with a capital of £60,000, to acquire the Continental patents for the pneumatic tool described in *Industries*, Vol. IV., page 157; the Schanschieff Electric Light and Power Company, Limited, with a capital of £200,000; and the Julien Electric Company, Limited, with a capital of £100,000.

HEMP.—For spot sales of Russian hemp full prices are obtained, stocks being small, and moderate business has been done in futures at advanced rates. Italian hemp is unchanged. There is little doing in Manilla hemp for immediate delivery.

SUGAR.—Sales by refiners have increased, the stocks in the hands of dealers being low, but the market continues quiet.

SHIPPING.—A deputation from the Chamber of Shipping has had an interview with the President of the Board of Trade with reference to the necessity, in the interests of British shipping, of applying certain rules to foreign vessels trading with this country. The speakers suggested that the load line should be applied to foreign ships, and discussed several other points. Attention was also drawn to the importance of improving the means of access for large steamers to the Thames. The London and St. Katherine Docks Company announce that a new direct route will be opened on Saturday between Hamburg and St. Katherine Docks, by a service of steamers three times a week. On the motion of the Earl of Onslow, the Merchant Shipping (Life Saving Appliances) Bill has been read a second time in the House of Lords. Messrs. H. E. Moss & Co. in their circular state that in spite of what has been lately said about the large amount of tonnage under construction, there is not much fear of the freight markets being swamped. As it is, the building yards could accommodate twice the number of ships at present in hand. The firms now contracting for vessels are of a better class than those who went into shipping ventures between 1882 and 1884, and have practical knowledge of steamship management. Messrs. Moss state that the rumour of an intention by Lloyd's Committee to increase the scantling of steel built vessels has caused some owners to make inquiries about vessels of iron, and there is a probability of a slight reaction in favour of building with the latter material. Another thing that is having much weight is the difficulty in getting quick delivery of steel plates, the demand being so great and the manufacture so limited, while the production of ship plates of iron is practically unlimited. In connection with this subject, it is mentioned that heavy contracts for steel plates and angles have been placed in Belgium by some shipbuilders. Almost every contract placed during the last six months is for steel hulls and triple expansion engines.

RAILWAYS.—The gross receipts of the twenty-three principal railways in the United Kingdom, for the week ending 18th March, amounted to £1,103,074 on 15,850¼ miles, as compared with £1,089,675 in the corresponding period of 1887, when the mileage was 15,708¾ miles. An increase is thus shown in the mileage of 141½ miles or 0·8 per cent., and in the receipts of 1·2 per cent.—A Select Committee of the House of Commons has passed a Bill authorising the construction of the proposed Metropolitan Outer Circle Railway, which will pass through Ealing, Sudbury, Kinsbury, Hendon, Finchley, Southgate, and Tottenham.

FOREIGN EXHIBITIONS.—At the first meeting of the Executive Council of the British Section of the Paris Exhibition the financial aspect of the matter has been discussed, and it has been decided to make a charge of 5s. per square foot to cover the various expenses which will be incurred in fitting up the courts, &c. Should any surplus be left, the exhibitors and guarantors will decide what shall be done with it. The guarantee fund already exceeds £12,000, which it is anticipated will be largely increased. The Council will be glad to hear from firms of high standing who intend to exhibit, and information may be obtained at the offices of the British Section, 2, Walbrook, E.C.—The Secretary of State has communicated to the Society of Arts a dispatch from the British Ambassador at Madrid, stating that the first batch of goods for the Barcelona Exhibition has arrived from Germany and Austria, and that great efforts are being made to insure the success of the French portion of the Exhibtion. It is stated that there will be over 30,000 exhibitors, of whom only eighty are English.

THE NAVY.—Owing to the falling off of the amount of boiler work at Sheerness Dockyard, about forty-five men will have to be discharged.—A successful trial was made on the Thames on Monday of a new torpedo boat, built by Messrs. Yarrow & Co., of Poplar, for the Government. She is 56ft. long by 8ft. 3in. beam, and has a displacement of 10 tons light and 14 tons loaded. Her speed is 16 knots per hour. —The new armour plated barbette ship "Rodney" has completed the trials of her four 69-ton breech loading guns at Sheerness, and is ordered to be ready for sea by Saturday, 31st March.—The Admiralty has decided that in future midshipmen in the navy will have to acquire a knowledge of steam and marine engineering, and instruction will be given to them during the last two years of their term of service in these branches.

GLASGOW, 29TH MARCH, 1888.

THE GLASGOW CENTRAL RAILWAY BILL.—This Bill, promoted by the Caledonian Railway Company, came before the Lords' Committee on Opposed Bills last week. Although the standing orders were held not to have been complied with so far as regards the promotion of the Bill by the Caledonian Railway Company instead of the original promoters, this will not interfere with the progress of the Bill, but it will now be pushed forward by the original promoters. It is, of course, open to the Caledonian Railway Company to purchase the undertaking immediately after it receives the royal assent, should it reach this stage.

SHIPBUILDING.—Messrs. Macmillan & Son, Dumbarton, have contracted with foreign owners for the construction of a steamer of 1200 tons. The Ailsa Shipbuilding Company, Troon, have entered into a contract with Captain Weatherill, of Dublin, for the construction of a steel screw steamer of 500 tons, with triple expansion engines of 500 i.h.p.

ENGINEERING.—Messrs. Brownlie & Murray, Possil Park, have just contracted for the erection of a sugar factory for a foreign firm. The building is to be 400ft. by 85ft.

PATENT CASE.—An important patent case, in which a Glasgow firm was involved, has just been made the subject of a judgment of the House of Lords. The United Horseshoe and Nail Company, Limited, London, sued Messrs. John Stewart and Co., iron and steel merchants, Oswald-street, Glasgow, for alleged infringement of two patents for machinery for the manufacture of horseshoe nails, claiming damages to the amount of £10,000. The London company had been selling through their agents in Scotland (Messrs. John Donald & Son, Glasgow) horseshoe nails manufactured by their patent machinery, and allege that Messrs. Stewart purchased from a Swedish firm quantities of nails produced by machinery which violated the patent rights in question. An interdict against the sale by Messrs. Stewart of these nails was sought for and obtained; but there remained the question of damages. When the case came up before the Court of Session in Edinburgh, Lord Kinnear awarded £530 to the London company; but on appeal to the First Division of the Court of Session, the damages were reduced to £50. Against this judgment an appeal was taken to the House of Lords, and here the judgment of the First Division of the Court of Session has been reversed, and the decision of Lord Kinnear affirmed. The damages payable by the Glasgow firm are thus fixed at £530.

INTERNATIONAL EXHIBITION.—The fairy fountain is now approaching completion, and Messrs. Doulton's fountain is also making good progress. The barricade which will shut off for the purposes of the Exhibition a large portion of the West End Park, is being erected. The bishop's palace, the refreshment rooms, and the switchback railway are practically finished. The second bridge over the Kelvin, for the service of the Exhibition, has been built. Exhibits are now beginning to be put in their places, and altogether the arrangements are well forward.

(From our own Correspondents.)

LIVERPOOL, 28TH MARCH, 1888.

NEW WHOLESALE FISH MARKET.—On account of the great increase of the fish trade of the port, which last year amounted to about 25,000 tons, the existing premises were found to be totally inadequate for the requirements of the trade. Fresh plans have been drawn out by the city surveyor for new premises to be erected on the site of Lucas' repository. In the presence of the City Council, and others interested in the movement, the foundation stone was laid by the Mayor on Monday last.

Digitized by Google

THE PIPE TUNNEL UNDER THE MERSEY FOR THE VYRNWY WATER SUPPLY.—At the meeting of the Water Committee held on Monday last, the tender of Messrs. Monk & Newall for constructing the tunnel to convey the double line of pipes under the Mersey at Fiddler's Ferry, from the Vyrnwy Valley to the Prescot reservoir, was accepted; the amount of the tender being about £20,000.

THE CUNARD STEAMSHIP COMPANY.—The annual report of this company states that the profits of the working or revenue account is £263,983. 17s. 6d.; the amount at the credit of the profit and loss account, after payment of debenture interest, is £254,482. Of this sum £135,500 has been transferred to the depreciation fund, and £77,839 to the insurance fund; £40,000 of the remainder is recommended for payment of dividend, at the rate of 2½ per cent. per annum. The rates of freight had been very low, but there had been a considerable increase in emigration. A larger number of cabin passengers had been carried than in the year before. The "Umbria," "Etruria," and "Aurania" have been fitted with gun platforms, to enable them to act as armed cruisers, in accordance with the agreement of the company with the Admiralty.

SHEFFIELD, 28TH MARCH, 1888.

THE STATE OF TRADE.—There is a good demand for manufactured iron. Bars are selling at £5. 5s. per ton, with an upward tendency. The returns made to the Board of Conciliation as to the decreased output of manufactured iron for January and February this year, compared with that in the two closing months of last year, has not caused any surprise, for makers had large stocks, and these in some cases have not been worked off to any extent. The next two months should show a decided improvement, for both iron and steel are in extensive demand. Plates for shipbuilding, propellers, heavy machinery, and boilers are yielding plenty of employment, and there is, in fact, in most of the heavy departments a steadily developing trade. There is much industrial enterprise in the town. Firms are putting down improved plant and machinery, and in not a few cases extending their works. The new forge at Grimesthorpe, put up by Messrs. Cammell & Co., for the production of great ingots, will soon be completed, and the Cyclops, as well as several other large Sheffield concerns will perhaps be busy before the year is out on material for coast defence, or more aggressive warlike purposes. The outlay in plant and machinery at the ordnance works recently erected in the local industrial quarter of Brightside is very great. At the foundries work is tolerably brisk, and the rolling mills are going almost constantly. One or two good orders have recently been received for heavy plant for use abroad; and the Japanese, who are making wonderful progress in industrial skill, are taking engineering work from Sheffield. Now that there is some prospect of the departure of winter, a brisker trade is being done in garden tools.

NORTH STAFFORDSHIRE, 28TH MARCH, 1888.

BANKRUPTCIES.—The public examination of Mr. Edward Williamson, late coal and iron master, trading as Kinnersly and Co., Clough Hall Iron Works, Kidsgrove, was continued yesterday, and eventually adjourned to allow of certain parties being examined in Chambers.—An application was recently made at Hanley to the County Court Judge, on behalf of Mr. T. W. Handley, of Manchester, trustee in the bankruptcy of John Nash Peake, colliery proprietor at Knutton and elsewhere, for leave to disclaim a lease of some mining property at Knutton, granted by the governors of the endowed schools at Newcastle-under-Lyme to the late Mr. Thomas Peake, and assigned by him to the bankrupt, from whom he obtained an indemnity against liability under the lease. The latter had spent in sinking pit shafts and putting up plant nearly £20,000, the greater portion of which, counsel stated, had been found by his creditors. The judge ordered that the trustee should have power to disclaim, but he gave the lessors six weeks in which they might buy the fixtures. If the interest in the fixtures was not purchased by the lessors, the trustee should have six weeks further, in which he should have a right to sell and remove such interest as he had in the fixtures of the bankrupt estate affected by the lease, and after that he is to be at liberty to disclaim.

NORTH STAFFORDSHIRE WATER BILL.—The North Staffordshire Water Works Company have failed in their effort to obtain special powers to bring a sufficient quantity of water by a process of gravitation from Moddershall Oaks to the town of Stone, the Committee of the House of Lords having decided that the preamble of their Bill had not been proved.

BIRMINGHAM, 28TH MARCH, 1888.

THE METAL TRADES.—In the metal trades of this district it is very common to hear the opinion expressed that the revival in trade, talked about so much recently, has quite disappeared. In the copper and brass industries, the high prices engendered by speculation are causing slackness. It is feared that the reaction which must come will not altogether suffice to bring about a return to the *status quo ante*. The inflation of prices is causing railway and other companies to substitute soft steel for copper in fire boxes, and brass in boiler and condenser tubes; and when once the cheaper metal has been proved to be practicable, the copper goods will not easily regain their former position. The world may, in the end, be the gainer; but a considerable amount of inconvenience and loss must for a time result. The constriction in the use of copper is leading to accumulation of stocks in the hands of the syndicate, and to sales at reduced rates by outsiders; hence it is thought that the stability of the copper combination is becoming less assured, and the near future may have some surprises in store for the brass trades. In the iron trade a tendency to quietness prevails, but restriction in the output of pigs is preventing any fall in prices. Wrought iron is chiefly in demand for sheets and for galvanising purposes, and prices are lower than at the beginning of the year, the fall in double sheets being about 12s. 6d. Galvanisers are busy on certain classes of goods, such as wire netting, which always go off well at this season; but in the larger branches, for example corrugated sheets, there is in some cases absolute slackness. Steel is in good demand.

LEICESTER, 28TH MARCH, 1888.

WOOL, SPINNING, AND YARN TRADES.—There is a slight change in the direction of better business. Prices are at present at such a low level that some buyers are of opinion that they cannot go any lower; some transactions have, therefore, been concluded at late rates. But this feeling is not general, and many consumers of the raw material are deferring their larger operations, and are content to buy only for their immediate wants. Country dealers and growers are not disposed to yield a fraction on late rates, and as staplers are not pressed, there is but little being bought. The demand for yarns is not very brisk, and spinners find some difficulty in keeping their machinery employed, and stocks, moreover, are as a rule fairly heavy. Cashmeres and fine yarns are mostly in demand; the bulk of the business done is at very narrow profits, and competition is remarkably keen all round. Yarn merchants are not doing a very good trade.

BARROW-IN-FURNESS, 28TH MARCH, 1888.

SHIPBUILDING.—The first official visit of the directors of the Naval Construction and Armaments Company, Limited, was paid to the works at Barrow this week. All the directors were present, including the Marquis of Hartington, Lord Brassey, and Mr. Nordenfelt. From the date of the formation of the company up to the present time attention has been chiefly directed to the preparation of the works for what is expected to be a very large trade, and the visit of the directors to Barrow is associated not only with the inspection of the new property acquired, but with large schemes for the construction of steamships of great size and power for mercantile and other purposes. In the course of a short time it is expected that the yard will be very busily employed; in the meantime the new company have booked their second order for a new steamer of the "Como" type. The "Como" was built by the Barrow Shipbuilding Company, and now the new company have secured the order for two duplicates of her. Of course the commencement of active operations at the yard of the new company will lead also to a brisker trade at the Barrow Steel Works in the production of steel shipbuilding material, so that Barrow will secure two advantages from this new enterprise. Shipbuilding at Whitehaven is in a better condition, three sailing ships being now on the stocks. Messrs. Westray & Copeland, at Barrow, have cut the Manx steamer, "King Orry," in two, and are putting an additional 30ft. in her midships, preparatory to fitting the new engines and boilers, which are in course of construction. By means of forced draught and other alterations, the Barrow Shipbuilding Company, through the Naval Construction and Armaments Company, Limited, are making progress with the Manx steamer "Mona's Queen," which will be on her station in the early part of the season, with accelerated speed.

IRON AND STEEL.—The depression in the iron and steel trades, reported last week, has not been maintained. A better demand has sprung up for hematite, and prices have moved upwards in sympathy, being quoted to-day at 43s. 3d., against 42s. 6d. last week. Makers, however, are not pressing sales, as they are busy, and expect better prices. In the steel trade there is a very firm tone, and in all departments the demand has strengthened. Heavy rails are quoted at £4 per ton, against £3. 18s. 6d. last week. Plates and angles, which are in better request, are quoted at £7 and £6. 10s. respectively; and billets, which are firm, at £3. 18s. 6d. Iron ore is quiet in tone, but firmer in price, 9s. to 11s. per ton net at mines for ordinary qualities.

MIDDLESBROUGH, 28TH MARCH, 1888.

FINISHED IRON AND STEEL.—Manufactured iron is unchanged. The works are going steadily, as there are plenty of orders. Most manufacturers have orders which will keep them going for some time, and these maintain the prices that they have been obtaining. In steel there is hardly the same activity as formerly, except in ship plates, which cannot be delivered as rapidly as wanted. The stormy weather, however, being unfavourable for shipbuilding, will so far enable the plate makers to keep pace with the work.

PIG IRON.—The attendance at the market on 'Change to-day was good, and the tone was steady and firm. As the month is drawing to a close there was little or no disposition to do business, except in small parcels urgently wanted. The unfavourable weather interfering with shipments has somewhat marred the expectations of holders of iron that prices would advance; buyers are content to wait to see what the returns will show. In the meantime the nominal price of No. 3 G.M.B. is still 31s. 6d. per ton. Forge continues to be much in demand, on account of the improvement in the wrought iron trade, so that even as high as 32s. has been given for approved brands From 30s. 9d. to 31s. is the usual price.

SHIPMENTS OF PIG IRON.—The weather having become more favourable the shipments have again maintained an increase over those of last year during similar periods. The weather is still far from settled, and has told upon the home consumption as well as on foreign exports.

NEWCASTLE, 28TH MARCH, 1888.

STEEL.—In the early part of the month Messrs. Hawks, Crawshay, & Sons made a successful commencement with the manufacture of steel by the Siemens-Martin process, and the effect of this new venture is already beneficially felt in the local shipbuilding yards, where the difficulty of obtaining necessary supplies of material has for some time past been a serious hindrance to operations. Only one furnace, capable of turning out about 200 tons of steel weekly, has as yet been put in operation, but the erection of a second furnace is now nearly completed, and it will be ready for work by the middle of April. Steel plates for shipbuilding are being produced in considerable quantities, and the firm have secured several forward contracts for material of this description. Among others may be mentioned one entered into with Messrs. J. L. Thompson, of Sunderland, for plates, &c., to be used in the construction of some of the large vessels now on the stocks at the North Sands yard. Messrs. Hawks, Crawshay, & Sons have also re-commenced the manufacture of iron ship and boiler plates, which they discontinued some years ago, and in this department of their business they are likely to be very actively engaged during the whole of this year. One of the two new Siemens-Martin furnaces recently erected in connection with Messrs. Palmer's steel works, Jarrow, has also been put in operation, and the other will be started by the end of the present week or the beginning of next. Messrs. Palmer are themselves large consumers of the steel plates, &c., manufactured in their works; but in addition to supplying their own wants, they have hitherto taken an important part in meeting the requirements of other shipbuilding firms on the North-East Coast. With the increased resources now at their command they will, of course, be able to do this more effectually, and will no doubt prevent a good many orders for shipbuilding material from going out of the district. Messrs. Spencer & Sons, of the Newbury Steel Works, are well supplied with orders for their various specialties, such as patent anchors, patent cranks, shafts, ships' stern frames, &c.

IRON.—A satisfactory tone is still manifested in the finished iron trade, and the substantial advance which was obtained some weeks ago in the price of plates and sheets is fully maintained. The rolling mills at Gateshead are working almost without intermission, a condition of things which offers an agreeable contrast to the state of matters a year ago, when they lay idle for at least two weeks out of four.

CHAIN AND ANCHOR WORKS.—The makers of small chains, at Messrs. Abbot's factory, Gateshead, are kept tolerably busy, but in the cable chain department there has been nothing done for the past three weeks, owing, it is understood, to some difference between the employers and the operatives, respecting the price to be paid for the work. In the anchor shops there is considerable briskness, the firm having a good many orders for Tysack's patent anchors to execute.

RIVET WORKS.—The rivet works at Yeams and Gateshead are extremely busy with orders, which are chiefly local.

DUNDEE, 28TH MARCH, 1888.

FLAX AND JUTE TRADES.—Little change can be reported in the staple industries of the town and district during the last fortnight. There is no disposition to do forward business with the United States until something definite is known about the proposed alteration in the tariff. In flax there is less doing, if anything. Spinners seem to have satisfied their wants for the present. Russian reports are somewhat firmer, and their exchange has risen slightly. Flax and tow yarns are difficult to move, but stocks are understood to be small, and with a little more activity prices will probably advance. The demand for linen goods is still quiet. Manufacturers are fairly well employed, and as quotations are lower, it is anticipated that orders will now come in more freely both from home and abroad. Sailcloth is in good demand at late prices. There have been large arrivals of jute, and some parcels have been sold from the ship's side at 2s. 6d. to 5s. below recent rates. There is not much buying for shipment, as the Calcutta market remains firm. The demand for jute yarns is scarcely so active, but spinners are all well foresold, and are very firm in their quotations for quick delivery. In jute, good Hessians barely maintained late values. The demand is not equal to the production, and for some widths buyers have the advantage. Sacking and bagging move off freely at firm prices. There is also a steady inquiry for the narrower widths of tarpaulin.

THE ISLE OF MAN STEAMER "QUEEN VICTORIA."

The celebrated steamers which were last season placed on the Isle of Man and Liverpool route, by the Isle of Man, Liverpool, and Manchester Steamship Company, Limited, as the pioneers of the new Manx Line, excited a great amount of public interest, on account of the exceptionally fast passages which they made during the season. We recently, in a two-page supplement (see *Industries* of 29th January last), gave a general view of the engines of the "Queen Victoria," and in our two-page supplement this week we illustrate the hull of the vessel. The model is particularly handsome, being designed for high speed. The spacious deck accommodation affords a splendid promenade, the vessel being intended for day service only. The dimensions which apply to the "Queen Victoria," as well as to her sister vessel, the "Prince of Wales," are as follow: Length, 340ft.; breadth, 39ft.; depth moulded, 24ft.; gross tonnage, about 1500 tons. There are eight water tight bulkheads, seven of which are carried up to the main deck. Communication between the compartments is controlled by self closing doors (Shepherd's patent, see *Industries*, Vol. III., page 81). The sides of the vessel are plated up to the upper deck forward of the paddle boxes. The shelter thus formed is lighted by unusually long side lights. Abaft the paddle boxes, the sides are open above the line of the main deck bulwarks, for the purpose of light and ventilation. A spacious smoking room and large refreshment bars are special features of these vessels. In a large deck house there is a series of reserve state rooms, fitted in a luxurious manner. The whole of the after part of the vessel is fitted up for first class saloon passengers, second class passengers being accommodated forward. The dining saloons are arranged apart altogether from the general sitting saloons, and there are, moreover, private rooms for select dining parties. The working appliances of the vessel are of the most recent type, comprising steam capstan windlass forward and steam capstan aft, and steam and double screw hand steering gears. One of the special features of the vessels is the completeness of the outfit of life saving apparatus. Four large lifeboats (two of which are always hung outboard on the davits with patent detachable hooks), several patent reversible seat lifeboats, and collapsible boats afford very ample accommodation for the whole of the passengers in the event of a catastrophe. We intend to give the details of the engines of these fine vessels in an early issue.

A NEW METHOD OF ROLLING TUBES.

By our Düsseldorf Correspondent.

For some time past German rolling mill engineers have been discussing the probability of success of the new method of rolling tubes, which has been invented by Herr Reinhard Mannesmann, of Remscheid; but as the inventor has as yet not suffered the details of his process to become publicly known, no very definite opinion could be formed in technical circles. Some engineers here expect the new process to completely revolutionise the rolling of tubes and articles of this kind, whilst others will only allow the invention a very limited sphere of application, and Herr Martin Balcke, in a paper recently read before the Society of German Engineers, even goes so far as to condemn the new system altogether. This criticism is based on the supposition that the tubes produced by the new process are weaker than welded tubes, and that an excessively large amount of power is required to drive the new rolling mill. It need hardly be said that both objections are purely conjectural. Where opinions are thus divided, some definite information on the subject will probably be of interest to the readers of *Industries*, and with a view to lay the facts before them, I recently paid a visit to the works of the inventor, and inspected the new rolling mill and some tubes made by it. The invention is protected in Germany by Patent No. 34617, but the specification is so vague that no definite idea as to the details of the invention can be formed from a perusal of its contents. In the German patent the inventor claims to be able to roll in a single pass all kinds of sections, including tubes with ribs and other projections; but, as a matter of fact, he has up to the present confined himself to the rolling of straight tubes only. The American patents are more definite, and the sketches which accompany this description are reproduced partly from the American patent specification. The numbers of the American patents are from 361954 to 361963.

The only rolling mill on the new plan which has yet been built and practically worked, is a small one at the works of the inventor in Remscheid. I have seen tubes of various diameters, and up to 10ft. in length, rolled by this mill without a mandrel out of solid blocks of Bessemer steel, Thomas steel, and Delta metal. All the samples were perfect in appearance, and to judge from the manner in which they can be bent and the edges flanged over, the strength of the tubes is certainly greater than that of ordinary welded tubes of the same dimensions and materials. The success achieved with this experimental mill has induced one of the largest German tube works (Pönsgen, of Düsseldorf) to adopt the process, and to set apart a portion of their works for the rolling of tubes on this system. A large rolling mill on Mannesmann's principle has been there erected, and will be driven by a large engine of 800 h.p., running at 150 revolutions per minute. A second installation on the same system is in course of erection at a tube works in Saarbrück, and a third in Komotau (Bohemia). These facts will show that the new process is of practical importance, notwithstanding the adverse criticism of some German engineers.

The principle on which the action of the new tube rolling mill is based will be understood from Fig. 1, where A and B are two conical rolls, the axes of which are situated in two parallel vertical planes; but each axis is inclined to the horizontal, so that the smaller end of roller A and the larger end of roller B are uppermost. The rolls are preferably provided with spiral corrugations, although this is not absolutely necessary. In the illustration these corrugations are only shown for the roll A, but it must be understood that all the other rollers shown in the figures may be similarly corrugated. The object of the corrugations is to provide a firmer grip on the block which is being worked. If the rolls revolve in the direction shown by the arrows, and a metal block C be inserted between their smaller ends, it will be gripped by the rolls and revolved, whilst at the same time, owing to the horizontal component of the rotary motion, the front end of the block will be drawn to the right. It is, of course, necessary to guide the block, so

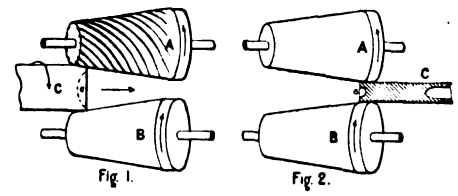

Fig. 1.

Fig. 2.

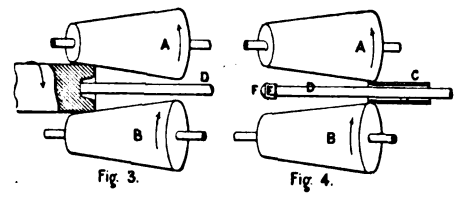

Fig. 3.

Fig. 4.

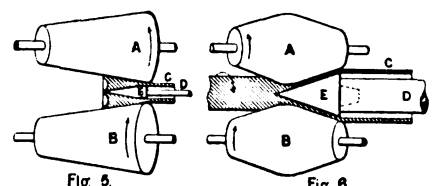

Fig. 5.

Fig. 6.

/Industries.

as to prevent its jumping out from the rollers. This can be done either by separate guide rolls or by placing a similar pair of inclined working rolls above and below the block. For simplicity of illustration the guiding arrangements are omitted. The effect of the rotary and forward motion imparted to the fibres of the material is to draw them out spirally, whereby the metal is taken from the interior of the block and transferred to the surface. The drawing out action on the surface of the block is greatest at the front end, where, owing to the larger diameter of the rolls, the speed is greatest, whilst at the same time the rear end of the block is prevented from following equally fast by the conveying surfaces of the rolls. At the beginning of the process a cavity C is thus formed, and as the block advances the diameter decreases whilst the cavity extends, so that when the whole block has passed through the rolls it presents the appearance of a tube open at the forward end, but closed at the rear end, as shown in Fig. 2. A small cavity *c* is also formed at the place where the tube leaves the rolls. A tube is thus formed out of a solid block in one pass, and the dimensions of the finished tube depend upon the form of the rolls, their distance apart, and the inclinations of their axes. It will be seen that this process of rolling tubes is fundamentally different from the ordinary method. In the latter the rolls revolve in opposite directions, so that their working surfaces where they come in contact with the block have the same direction in space, and the block passes at right angles to the axes of the rolls which are parallel. In this new mill the rolls revolve in the same direction, and their working surfaces, where they are in contact with the block, travel in opposite directions, imparting to the latter a rotary movement, whilst the block advances approximately parallel to their axes. It is also evident that with this system the tubes can only be open at one end, since the tubular formation must cease as soon as the retarding influence of the conveying surfaces of the rollers on the rear end of the bar ceases. If it be desired to obtain tubes open at both ends, it is necessary to employ a mandrel, as shown in Fig. 3. In this case the block must be well heated before being put between the rolls. The mandrel has the effect of keeping back the centre portion of the block, especially towards the end of the pass. The illustration represents the moment when the tubular formation has begun, and the bottom of the cavity has come in contact with the end of the mandrel. The other end of this mandrel is supported in a footstep or thrust bearing, so that it can revolve with the block. In some cases a detachable head E is attached to the mandrel (Fig. 4), and when the pass is finished a small quantity of metal F is generally torn off the rear end of the tube. If the material to be operated upon is very ductile and soft, previous heating is not required, and in that case a mandrel D with a pointed head E (Fig. 5) is used. The rolls A and B then act partly as faced rollers, which push the block C over the end of the mandrel. The same apparatus may also be used to reduce the thickness of tubes previously rolled, as above described. The inner diameter is then determined by the size of the mandrel head, whilst the outer diameter depends upon the distance between the larger ends of the rolls. For certain very soft materials the inventor finds it advantageous to assist the feeding motion of the rolls by providing the mandrel with a screwed head and revolving it by power. In this case the material is fed from the inside as well as from the outside, and the fibres are arranged spirally throughout the length of the tube. In all previous arrangements the size of the finished tube is smaller than that of the original block; but where it is required to produce a tube of larger diameter than the block, Herr Mannesmann adopts rolls of the form shown in Fig. 6. In this case one half of the rolls act as shown in Fig. 1, whilst the other half simply serve to enlarge the tube thus formed. The material is also in this case fed forward by the horizontal component of the surface motion of the rolls, and the tubular formation begins slightly before the middle is reached, where the diameter of the rolls is greatest. From that point the metal is spread out by the insertion of a mandrel with a conical head, and thus a tube of larger diameter than the original block is produced.

THE EFFECT OF SEA WATER ON PORTLAND CEMENT.

At a meeting of the Society of Engineers, held on the 5th inst., a paper was read on the above subject by Henry Faija, M.Inst.C.E.

The paper referred to the failure of certain concrete work at Aberdeen Graving Dock, and the author first alluded to the several published reports ascribing the failure to the chemical action of the sea water on the cement. After pointing out that Portland cement has been used in marine works for forty years, and that until now any failures that may have occurred have never been traced or ascribed to the chemical action of the sea on the cement, the author gave a general description of the work carried out at Aberdeen, embodying extracts from the reports of Mr. Smith, Professor Brazier, and Mr. Messent, descriptive of the manner in which the cement was used, the specification to which it was supplied, and the argument on which their theory is based—which is, briefly, that the magnesia precipitated from the sea water enters into and becomes a compound part of the cement, thus destroying it. The presence of magnesia in cement was then considered, and the reason explained why it is deleterious when in excess; but the magnesia as precipitated from the sea water was shown to be in a very different condition to magnesia when it is incorporated in a cement in the course of manufacture. The result of a large number of experiments, comparing the behaviour of cement when gauged in sea water and when gauged in fresh water, the analyses of the cements before and after gauging, and of the scale on the surface, together with the scum and sediments in the waters in which the cement had been placed, were given. The specification and the analysis of the cement used at Aberdeen were then considered, and it was pointed out that, though such a specification was not antagonistic to the production of a good cement, there was nothing in it which insured a good and sound cement being delivered, and it was suggested that one or other of the methods now known for determining the soundness of a cement should in all cases be used, the author being of opinion that, given that a cement is well ground and is proved sound, it will, in nearly all cases, be strong enough for any purpose for which it is likely to be used. The concrete at Aberdeen was used in what is called a "plastic" form—*i.e.*, it was allowed to partially set, and was then broken up and placed in position. The danger of using cement in this manner was shown, and the results of several experiments given, proving that under certain conditions the cement never re-sets. The conclusions arrived at were that sea water has no deleterious chemical action on a sound and properly used Portland cement, and that the failures at Aberdeen must be attributed to some other cause: either to an inherently bad cement having been used, or to the injudicious use of it in a plastic form.

Advertisements intended for insertion in the current week's issue must reach the Manchester Offices not later than first mail delivery on Thursday morning. Scale of charges for displayed advertisements on cover and inside pages will be forwarded on application. Orders for single advertisements must be accompanied by payment in order to insure insertion, the charge for which is 2s. 6d. for the first four lines or under, and 8d. for each additional line; one inch and over at 7s. per inch; the line averages eight words. While all practical regularity in the insertion of serial advertisements will be observed, it can only be absolutely guaranteed in the case of those ordered to appear weekly.

All accounts are payable to the Publisher, JAMES F. BUTTERWORTH, *70, Market-Street, Manchester. Cheques should be crossed Manchester and Liverpool District Bank, King-street Branch, Manchester. Post Office Orders to be made payable at Manchester.*

Industries:

FRIDAY, 30TH MARCH, 1888.

DEFENCE OF OUR MERCANTILE PORTS.

LORD RAVENSWORTH did well, as President of the Institute of Naval Architects, to use his opportunity to force home to the representatives of the shipbuilding industry assembled in the hall of the Society of Arts a truth which is giving rise to some alarm throughout the country, viz., that our mercantile ports lie open to an attack from an enemy's cruisers. To the community of shipbuilders and shipowners, to whom the question appeals directly, it is perhaps sufficient to make the danger known to insure a willing co-operation on their part with the Government in the efforts about to be made to avert the evil; but the risks to which our trade and industry are exposed through this source may need to be insisted upon to make their importance felt by all classes of manufacturers. Yet a very little reflection will reveal the true magnitude of the interests at stake. In every sense it is a national question, affecting deeply all our great industries. We cannot contemplate without dismay the consequences of a successful attack upon even one of our principal mercantile ports. In a time of war these would be crowded with shipping, among which a single armoured cruiser, accompanied by torpedo boats, could in a few hours make ruinous havoc. It is, too, in these ports that our great shipbuilding yards are situate, the partial destruction of which would seriously impair our commercial life. Moreover, an occurrence of that nature is to be feared from the disastrous moral effect it would produce. Lord Ravensworth aptly described it as a stab at the heart that would paralyse the vital powers. Our possible enemies must be equally cognisant with ourselves of the character of these places, and we have no ground for assuming that the policy of striking at our most vulnerable part will fail to recommend itself to their judgment. We should make ourselves guilty of suicidal folly by obstinately shutting our eyes to the risks to which we are exposed. Our extensive coast line and numerous ports render it extremely difficult, in these days of steam, armoured ships, and long range guns, for our fleet to guard effectively every pregnable point. A few swift armoured cruisers, resolutely handled and aided by torpedo boats, might do incalculable mischief before a sufficient force could be brought to bear upon them. This is the danger apprehended, and it is solely against such attacks that the Government now seek to make provision. That the danger is real is shown by the unanimous testimony of the witnesses examined by the Committee whose report has just been made public; and that it is imminent the actual state of Europe affords sufficient evidence.

The opinions of the Committee appointed by the Secretary of State for War to consider with him the plans proposed for the fortification and armament of our military and home mercantile ports, will be received by many more readily because the civil element largely predominated in its constitution. The members were: Sir W. H. Houldsworth, M.P., Admiral Sir W. M. Dowell, Lieutenant-General Sir E. B. Hamley, Sir F. Bramwell, J. W. Lowther, M.P., G. L. Ryder, of the Treasury, S. Whitbread, M.P., and E. R. Wodehouse, M.P. This Committee have arrived at the conclusion, from the evidence brought before them, that the kind of attack most to be apprehended is that of armoured cruisers, accompanied by torpedo boats and other small craft, which, say the Committee, can be repelled by submarine mines and torpedo boats. They add: "The special importance of the Tyne, the Clyde, and the Mersey may, however, necessitate the addition of a heavier armament." The Committee is further of opinion that where mercantile ports are situate at some distance up a river, submarine mining defence will in general afford very great protection. But whenever this defence is adopted, it is essential that the mine fields be protected by quick-firing guns. Basing the recommendations upon these conclusions, the Committee advise the immediate construction of works and the provision of armaments, sufficient to meet the case. It is suggested that the mercantile communities interested in these ports should contribute something towards the cost of the additional defences recommended, and definiteness and point are given to the suggestion by an expression of opinion to the effect that the local authorities might be expected to provide the sites for the forts and pay for the civilian labour, in doing which they would only be following well established precedent. The giving of land for forts and barracks dates as far back as 1701, so that to call upon the local authorities to furnish, free of charge, the ground on which works for the protection of their towns are to be built is not a new departure, but, on the contrary, it is a practice that has long prevailed in this country. In places where an active defence is of paramount importance, it is suggested that it may be better to endeavour to induce the locality to undertake the cost of the torpedo boats which it is necessary to provide for the defence of the port. In all cases, say the Committee, the local authorities should be expected to provide the necessary garrison, in the form of volunteer artillery or submarine miners. These are the points on which the commercial community is to be asked to co-operate with the Government, and we make no doubt that the invitation will call forth a ready response. The ports to be defended are: The Mersey, the Clyde, the Bristol Channel, the Humber above Grimsby, the Tyne, Sunderland, Hartlepool and the Tees, the Forth, the Tay, Aberdeen, Falmouth, Dublin, Belfast, and Holyhead. The estimated cost is about two millions sterling.

The measures proposed are doubtless necessary, and being necessary are urgently called for. But the real character of such works must not be lost sight of. They are utterly incapable of maintaining a long defence, and are only fit to delay capture till help arrives from the fleet. This is, no doubt, an important service, sufficient, it may be, to save our shipping and building yards from destruction. But it is to be borne in mind that such service is to be rendered only on condition of there being ships of war in fighting order near at hand. Our safety depends upon the efficiency of our fleet, and upon that alone. If our second line of defence ever be broken through, nothing can save these mercantile ports. Even strongly fortified military places have almost invariably yielded to a vigorous organised attack from a hostile fleet. It is, therefore, of paramount importance to keep the navy in the highest possible state of efficiency. There is some danger that this scheme of defence for our mercantile ports may attract undue attention to itself, to the neglect of the more effective means. The Committee, in their report, have acknowledged

Digitized by Google

the vastly superior importance of the active defence. They have, moreover, pointed out a probable method of attack against which land fortifications are of no avail. "According to the balance of evidence of naval experts," they say, "the most probable danger to be apprehended is not a direct attack upon the ports, provided they are placed in a reasonable state of defence, but that armoured cruisers will be sent to watch the lines of our commerce converging upon them, and to intercept and destroy merchant vessels." They say, moreover, that no amount of passive defence can adequately provide against the danger, to towns on the seaboard, of bombardment, owing to the long range of modern guns. Our safety lies in keeping the command of the sea, a truth which our traders and manufacturers will do well to bear constantly in mind. Only through it may we hope to escape the terrible calamity of seeing our shipping captured, our building yards destroyed, our commerce crippled, and our industries ruined.

LORD BRASSEY'S NAVAL ANNUAL.

Lord Brassey has just issued his second Naval Annual. It is in every respect a decided improvement on its predecessor, and may be described as the most remarkable storehouse of information relative to the maritime branch of the public service that has ever been published. In addition to the 784 pages of matter, every line of which is not only important, but also interesting, it contains eight illustrations of the most recent additions to the Navy and the merchant marine, sixteen charts and plans of coaling stations, &c., several hundred diagrams of British and foreign war and merchant vessels, and nearly thirty additional illustrations of armour and ordnance of the newest types. The book is in four sections, the first being the work of Lord Brassey himself, the second that of Mr. F. K. Barnes, the third, on gunnery, that of Captain Orde-Browne, and the fourth, which deals with torpedoes, the production of Lieutenant Sleeman. One of the first things that strikes the reader of the "Naval Annual" is the remarkable diversity and complexity of ships of war. The work contains illustrations and details of vessels in every navy in the world, and scarcely any two of them are alike. This is the feature of the work that is most likely to interest the naval architect, shipbuilder, and engineer. This increased and increasing complexity necessarily involves increased expense in the production of the same nominal tonnage, and we therefore find that the average cost per ton is now-a-days more than double what it was a few years ago, and that the Navy Estimates, in so far as they are affected by new tonnage and repairs, are greatly on the increase. The dockyard expenditure accounts show that for the last financial year dealt with there was expended :—

	Dockyards. £	Private contract. £	Total. £
On armoured ships.....	990,833	877,281	1,878,114
On unarmoured ships...	613,785	1,245,562	1,859,347
Totals.....	1,604,618	2,131,843	3,737,461

The increase of contract work is a feature of the year's work upon which the country and the Admiralty may both be congratulated. The quality of such work may not always be equal to dockyard work, although there is no reason why it should not be, nor may it even be found in all cases equally economical; but the country is likely to be better satisfied when naval constructions are given out to tenders, resulting in a strong competition among a number of high class and responsible firms.

While Lord Brassey never loses an opportunity of insisting upon the great importance to England of maintaining her navy in the highest possible state of efficiency, and lays down a definite programme as to what is still necessary to make it an irresistible fighting machine, his pages bear testimony to the very considerable increase of superiority that has taken place within recent years.

The often debated question of whether France is inferior as a naval power to England, and if so, to what extent, would appear to be completely set at rest by a statement of the number and tonnage of the vessels belonging to each country which Lord Brassey has drawn up, and which shows the following results :—

Vessels.	England. No.	England. Tonnage.	France. No.	France. Tonnage.
Armoured, first class.....	24	234,440	10	105,245
„ second class...	24	143,140	18	126,270
„ third class ...	11	92,110	5	23,508
For coast defence	13	40,390	14	35,293

This table shows that England commands a fleet of seventy-two vessels, of 510,080 tons displacement, as compared with forty-seven vessels, of 290,321 tons displacement, possessed by France. Russia has thirty-seven vessels, of 164,991 tons displacement. England's fleet, therefore, is more than equal to the combined fleets of the two next most important naval powers in Europe; and if we take the relative number and tonnage of first class armour clads into account, the superiority is much greater than it would appear as expressed by tonnage alone. The following statement shows the amounts expended on the chief navies of the world in the latest financial year :—

Country. Year 1886-87.	£
France	9,141,700
Germany	2,280,145
Austria.....	886,365
Italy	3,768,700
United States	3,646,660
United Kingdom	11,866,000

This record shows that the *effective* expenditure on the British Navy (for these figures do not include the non-effective expenditure, amounting to £2,036,000), largely exceeds that of any other country. On the whole, and in spite of much waste and possible maladministration, there is reason to believe that England gets as good a return for her money as any other country. This, however, by the complexity of the accounts, is not made quite so clear as it might be made. It is, for example, impossible to believe that private contract work costs on an average, for unarmoured ships, about £51 per ton more than dockyard work, and yet this is the conclusion to which the Admiralty returns point. This will be clear from the following table, which we abstract from larger tables given by the author :—

Year.	Average cost per ton. Dockyard. £	Contract. £
1879-80	69·80	152·00
1880-81	73·00	124·66
1881-82	73·00	123·26
1882-83	80·00	110·00
1883-84	93·88	131·56
1884-85	78·00	145·58
Averages	77·84	128·80

The solution of this enigma is probably that in the dockyard expenditure there should be items charged that are omitted and debited to some other accounts. But there is nothing to enable us to identify this fact, and as the figures now appear, they do a manifest and serious injustice to private shipbuilders, which the Government of the day should at once be asked to explain, and if possible, redress.

One of the most serious items in the annual naval budget is the cost of the repairs and alterations of armoured ships. It may be, and probably is, necessary that this expenditure should be incurred, in order that ships that are not perfect in their aggressive power should be brought up to the most modern conditions of efficiency. The figures, however, suggest that there has been a great deal too much pure experimentation on the part of Admiralty constructors, and not a little failure. Thus, we find that between 1880 and 1886, £120,873 were expended in repairs and alterations to the "Hotspur;" while there are corresponding items of £131,546 in respect of the "Bellerophon," £111,829 in respect of the "Audacious," £85,723 in respect of the "Iron Duke," and £84,655 in respect of the "Black Prince." Twenty-eight ironclads have involved an expenditure for repairs and alterations of not less than £1,471,709 between 1880 and 1886, being an average of nearly £53,000 per vessel. The total outlay on the repairs and maintenance of the fleet during the last ten years has been about nine millions sterling, or £900,000 per annum. During the same interval the cost of new construction has advanced from less than one and a half million to over three millions a year, the tonnage built by contract and at the dockyards having been since 1880-81 :—

Year.	Dockyard. £	Contract. £	Machinery. £	Total. £
1880-81	891	236	299	1426
1881-82	1150	292	240	1682
1882-82	1174	301	292	1767
1883-84	1187	236	507	1930
1884-85	1333	449	459	2242
1885-86	1153	1550	1003	3737
1886-87	1480	1430	746	3656
1887-88	1473	1017	568	3058

£1 = 1000.

It will be observed that 1885-86 is the only year in which the contract built tonnage exceeded in value that built by the Admiralty at the dockyards. In each year, however, the machinery has been mainly supplied by private firms, so, that when the machinery is added to the hulls, private contractors have had a considerable, if still inadequate, share of the work.

A subject which is of considerable importance at the present time to English shipbuilders, inasmuch as it is likely to lead to their direct profit and advantage, is the re-construction of the Spanish Navy. The "Annual" states that the programme of new ships to be built in respect of the expenditure of £9,000,000 sterling recently resolved upon by the Cortes, includes three cruisers at £280,000 each, eight cruisers at £200,000 each, six torpedo cruisers at £100,000 each, four torpedo cruisers at £80,000 each, ninety-six torpedo boats at £24,000 each, one transport, to be fitted as a floating factory, at £100,000, and a number of minor vessels of different kinds, bringing the total cost of new ships about to be constructed up to £7,596,000, in addition to a sum of £904,000 to be expended on vessels at present under construction. At the present time the Spanish Navy is perhaps the most backward of any in Europe. Of five ironclads, one alone is modern, and it is remarkable that the new programme fails to provide for the remedy of this serious defect. The navy of Spain has three completed first class cruisers of 3000 tons and upwards, and four in course of construction, as well as three modern second class cruisers and a torpedo flotilla of seventeen vessels. It is manifest that much remains to be done in order to bring the Spanish Navy up to a standard of efficiency commensurate with the importance of the country and its extensive seaboard, and in the adjustment of this balance Great Britain is likely to play a prominent and profitable part.

Russia is another country that has hitherto been backward in the extent and quality of its fleet. But the "powers that be" are determined that this reproach and danger shall be wiped out with the least possible delay. A shipbuilding programme has recently been adopted by the Russian Government, which provides for the construction of seventeen first class ironclads for the Baltic and the Black Sea, with a large equipment of gunboats, cruisers, &c., estimated to involve an expenditure of £15,468,000, in addition to £1,904,000 for artillery and £559,000 for torpedoes. This expenditure, judiciously applied, should give Russia the command of a fleet second only to our own. The Minister of Marine calculates the cost of the various vessels required at £503,791 for each first class ironclad, £408,000 for each second class ironclad, £195,916 for each cruiser, £25,000 for each gunboat, and £8,750 for each torpedo boat. These figures, it will be observed, are much under the cost of the same class of vessels in our own country, from which it would be inferred either that naval construction is cheaper in Russia than in England—which is extremely unlikely—or that the Russian ships will be of inferior power.

AMENDMENT OF THE PATENT LAW

It is highly probable that during the present session an attempt will be made to remove some of the more prominent defects of the Patent Law, which has now been in operation for upwards of four years. The Institute of Patent Agents have had the subject under consideration for a long time past, and have, with practical unanimity, formulated a set of proposals which, we believe, will command general approval. It would have been easy to have suggested many other important improvements, but we believe that we are correct in stating that Government support could not be obtained in the present condition of public affairs for any proposals which would be likely to give rise to prolonged discussion. It is difficult to conceive what material opposition can be raised to the proposals made by the Institute, and which are not put forward in the interests of any clique, class, or profession, but are clearly intended for the good of all concerned.

The question of examination is one of the utmost importance, but it is also one that would be likely to give rise to prolonged discussion, and probably defeat the passage of the proposed Bill. Its consideration has consequently been deferred, but some of the consequences of the establishment of an examining staff, and the definition of their duties under the Act, properly form the subject of proposed modifications.

Under the 7th section of the Act, it is provided that, under certain circumstances, the Comptroller may require an application, specification, and drawings to be amended before he proceeds with the application, and no limit of time is given within which the amendment must be effected. It is clear that this affords an opportunity for fraud. An applicant may file an incoherent or vague document professedly relating to an invention. This quasi specification is returned to him for amendment in due course, but there is nothing to prevent his deferring the amendment until the period of provisional protection has nearly expired, at which time he may, if dishonest, include or describe an invention by himself or another of which he had no conception at the date of his application, and thus obtain a priority to which he is by no means entitled. It is desired that the time within which an amendment may be made should be limited, but it would probably be much more fair and more just to permit no amendment whatever, except of an obvious clerical or formal error, before the filing of the complete specification. The sub-sections which set forth that the Comptroller

Digitized by Google

shall give notice to applicants whose specifications appear to comprise the same invention, have not worked satisfactorily, nor does there appear to be the least probability that they can by any means be made to do so, and it is, therefore, proposed to strike them out. In section 11, which relates to the opposition to grant of patent, it is suggested that the grounds of opposition should be: (1) That the applicant has obtained the invention from the opponent, or from a person of whom he is the legal representative; (2) that the invention is described in a provisional or complete specification of an application for patent or of a patent of prior date, provided that the said provisional or complete specification was filed before the date of the opposed application, and provided that, when the opposition is based on a provisional specification, followed by a complete specification, the invention is described in the complete specification; (3) that the applicant's complete specification claims an invention other than the invention the nature of which was set forth in his provisional specification, which claim forms the subject of an application made by the opponent in the interval between the lodging of the provisional and complete specifications of the applicant. If these modifications are made, we believe that the number of frivolous or vexatious oppositions will be very few in future. Section 12 of the Act provides for the grant of a patent to the inventor, or to the inventor with other persons or corporations with whom he may be associated. It frequently happens that an inventor sells his rights before the grant of the patent, and it would therefore be a great advantage if, on his request, the patent could be issued to his nominee, precisely as in the United States.

For the first time it is permitted under the Act of 1883 to pay renewal fees after they have become due, but the Act imposed the conditions that a fine should be paid, and that the deferred payment could be accepted only in cases of accident, mistake, or inadvertence. Temporary poverty cannot, therefore, be accepted as a reason, but there is nothing to prevent a false allegation being made to secure the continued validity of the patent. Since a substantial fine is inflicted for the delay, there appears to be no sufficient reason why any further conditions should be imposed, other than the limitation of time, and it is proposed, therefore, to remove them. By sub-section 10 of section 18 it is enacted that no application for leave to amend a specification can be made when and so long as an action for infringement, or other legal proceeding in relation to a patent, is pending. It is proposed to remove this disability, but it is also proposed in the following sections to enact that an amendment made during legal proceedings should not be used or put in evidence for the purposes of the action without the leave of the Court.

In relation to compulsory licenses, which would at present have to be granted by the Board of Trade, which in other matters appears to be guided by the whim of the moment rather than on fixed principles, it is properly proposed that the Comptroller, who is a far more competent authority, should have the decision, with an appeal to the Law Officer. It is also suggested that the Comptroller should decide questions of prolongation, with a similar appeal. This would unquestionably be more satisfactory and logical than the existing system, which compels the movement of the cumbrous machinery of the Privy Council and a prodigious outlay for its lubrication. When a patent is revoked on the ground that the patentee obtained the invention in fraud of the patentee, a new patent may be granted to the original inventor, but this patent must bear the date of revocation. In such a case it is clear that the spirit of the Act will not be complied with, for the public may be restrained from using the invention for a longer period than fourteen years, while on the other hand an intermediate patent or publication might subsequently be held to anticipate and consequently to invalidate the patent so granted. The Institute propose either that the original patent should be re-issued to the true inventor, or that the new patent should bear its date. In section 32, which sets forth the remedy in cases of groundless threats of legal proceedings, it is suggested that legal doubts should be removed by clearly defining that the validity of the patent on which the threats are based should come in question. It is now enacted (section 36) that a patentee may assign his patent for any part of the Kingdom precisely as if the patent were originally granted for that part only. It is easy to reduce this section to an absurdity. Each assignee may amend the specification with the result that several entirely different patents may co-exist for the same invention. This section is impracticable and misleading, and should be repealed. The section permitting exhibition without prejudice of an inventor's rights is still more misleading, and should share the same fate; for it is cheaper to provisionally protect the invention at once, and thus prevent risk of fraud. The Institute desire that a definition of the words "within the realm," which occur in the Statute of Monopolies, should be defined in section 46; but probably the definition given in the schedule to the Act, Form D, is sufficient for the purpose.

At present the Comptroller may exercise his discretion as to the registration of a design, and frequently does so. It is proposed to remove the discretionary power, and consequently clothe the applicant with the risk of an anticipation, which would not be serious. When a design is registered it certainly should be open to inspection within a reasonable period, so that intending applicants could ascertain for themselves what was already actually protected. In such a case a copy of all textile designs should be deposited at the Manchester office. It is also proposed that the discretion of the Comptroller in respect to the registration of trade marks should be terminated, except in the event of a similar mark being already on the register for the same class of goods. The appeal from the decision of the Comptroller refusing to register a trade mark should be removed from the Board of Trade to the Law Officer, and the present cumbrous and expensive treatment of oppositions to registration should be simplified by substituting the Comptroller for "the Court," and by permitting an appeal to the Law Officer. The term "fancy word" in the definition of a trade mark has given rise to a great amount of annoyance and litigation, and might easily be strictly defined in an amending Act. Throughout the Act, in every case in which the Board of Trade is mentioned, it is proposed to substitute the Comptroller, and it will be readily admitted by those who have had experience of the action of the Board of Trade, under the Act of 1883, that such a substitution cannot be disadvantageous.

The ratification of the International Convention since the passage of the Act renders further explanation or additional rules necessary, as the procedure in an application for a patent previously protected elsewhere under the Convention is nowhere set forth, and may be varied without notice or reason.

The suggestions of the Institute conclude with the words: "There should be a register or roll of properly qualified persons to act as patent agents." This may appear, coming from such a source, to be a somewhat selfish recommendation, but there are some grounds of public policy for the enactment of such a regulation, which we have already discussed in these columns. We think that much more might have been said in this respect, but it is probably thought that this may be said with better grace and greater force by those outside the profession.

We have been able to discuss and set forth only very briefly the proposals made by the Institute, in order that our readers may have as long an available period as possible for their consideration before the proposed Bill is submitted to Parliament. The matter is one of great public importance, and one upon which the opinions of those directly interested should be expressed without delay.

Letters to the Editor.

ALTERNATE CURRENT TRANSFORMERS.

To the Editor of "Industries."

Sir,—I notice in your late issues, a series of reports of the discussion on the above subject at the Society of Telegraph Engineers and Electricians, which took place during my absence in America. Both Mr. Gordon and Mr. Crompton seem to be extremely doubtful of the possibilities of an alternating system—assuming certain details of working on which the efficiency of the system must depend to be impracticable. I allude to the coupling up of alternating machines in parallel, and the use of small machines instead of large ones. My company having interests in this system of distribution of electricity, I inspected several stations in the States equipped with complete Westinghouse plants. The practice in all of them was to use small dynamos, each dynamo running off a separate Westinghouse engine, the power being transmitted through a belt. They would have in the day time a sufficient number of machines running to just supply the required current (thus obtaining a maximum efficiency of both engine and dynamo), and as the demand for current increases, more machines are connected in parallel to the working system. The method of connecting in parallel has been brought to a simplicity that leaves nothing to be desired. The already working system and the fresh dynamo that is to be added to it are connected to two circuits on a small piece of apparatus, showing by two lamps the difference of phase of the two currents. Each lamp varies from a maximum brilliancy to "black out," at a comparatively slow rate, and not coincidentally. The "beats," of the lamps alter in respect to each other, until in a few seconds the lamps go out and attain their maximum brilliancy at the same time. When this point is reached the switch is put on and the machines are running in parallel without any disturbance taking place. Looking at the machine that is about to be switched on, the only evident sign at the moment of connection is a tightening of the belt from the load placed on it. One is bound to conclude, therefore, that "the bottom has been knocked out" of many of the arguments used in the course of the discussion above referred to, and that the concensus of opinion in this country in favour of distribution by means of transformers is fully justified and strengthened by what is being achieved daily in America.

Yours, &c.,

London, 21st March, 1888. E. Manville.

FIRE OFFICE RULES.

To the Editor of "Industries."

Sir,—We feel exceedingly alarmed at the prospect that opens out before us now that another set of rules has been published. It would be difficult to arrange at the present stage of the industry any set of rules the following out of which could better guard against dangers arising from electric lighting than those which have been drawn up by Mr. Musgrave Heaphey. The writer has seen a number of installations both on the Continent and in the United States, with the result of feeling assured that work of this kind in England is infinitely superior to that carried out in other countries, and there can be no doubt that our comparative immunity from fire arises from the judicious enforcement of proper fire rules. A number of installations in this kingdom, including one or two of the largest, has been carried out by us, always under the Phœnix Fire Office rules, and in no single instance has an electrical fire occurred. It must certainly be the experience of every contractor that there is no difficulty in obtaining the approbation of fire insurance authorities for installations conscientiously executed. If we are to have several sets of rules it will be impossible to tender for work without a specification, and this means an expensive item added to the price of electrical work for the services of a consulting electrical engineer in each case, whose presence is unnecessary when a duly qualified fire inspector fills the position free of cost to the proposed user of the electric light. We think that this is a matter for the leading contracting firms to interest themselves in, and there can be no doubt as to their opinion on the subject. To frame and impose rules it is necessary to have a status. What is the status of those who are seeking to introduce the new rules, and what authority have they to handle a matter which so seriously affects the trade without first consulting it? The matter is such a serious one that we trust more direct and public impeachment will quickly ensue.

Yours, &c.,

London, 22nd March, 1888. Installers.

[We print our correspondents' letter without being able to indorse it. It is evident that the writers of the letter have a somewhat erroneous idea of the nature of the new rules and of the status of their framers. While fully admitting the good service rendered hitherto by the Phœnix rules, and the fair and conscientious way in which Mr. Musgrave Heaphey carries them into effect, we cannot shut our eyes to the fact that some other insurance companies, for reasons best known to themselves, are averse to the adoption of these rules, and two companies have actually contemplated bringing out rules of their own. It was partly to prevent the multiplication of rules thus threatened that the Council of the Society of Telegraph Engineers and Electricians took the matter in hand by instituting a Fire Rules Committee, with instructions to draw up such general rules as would be acceptable to all the fire offices, without precluding the use of the more detailed Phœnix rules. The Society, whose status and fitness to deal with a matter of this sort can hardly be doubted, have thus adopted the best means in their power to prevent the evil of an indefinite mutiplication of rules, which our correspondents seem so much to dread.—Ed. *Industries*].

THE LOCAL GOVERNMENT BILL.

The singular change which has come over party politics could hardly be more clearly manifested than in the strange irony of fate which has led a Conservative Ministry to introduce by far the most comprehensive scheme of local government which has ever been advanced by responsible statesmen. The idea of decentralising political power, which has long been an element in French political discussions, has almost invariably come from those who profess to represent in a special manner the mass of the people. It is a new, but quite a natural experience, to find the devolution of political power by a central authority proposed by those who may be presumed to represent in a special manner that authority itself. For in England, at any rate, government has become a function of extreme and increasing difficulty. Howsoever ardently some men desire to share in the exercise of that function, the strain involved in its exercise in a nation whose government is so democratic as ours is peculiarly laborious, and the problem of how to procure men sufficiently able and sufficiently popular both as administrators and as debaters is one that must tax the resources of either political party as occasion arises. The vast arrears of Parliamentary business, the slowness with which measures of practical importance are carried through the forms of either House of Parliament, and the obvious absurdity of discussing matters of purely local interest in an assembly of uninterested individuals from other localities, or even to an array of empty benches, have combined to force upon the attention of many Governments the urgent need not to extend the area of Parliamentary business, but to diminish it. Mr. Ritchie's scheme is extremely comprehensive. He proposes practically to hand over to County Councils the administration of local affairs, thus giving into their hands a great number of matters which are at present administered from the offices of the Government Departments in London. The County Councils so established would be representative bodies; the districts over which they possessed administrative powers would be divided into single member constituencies. A very decisive confirmation of the principle of popular election, which for good or evil is a potent factor in English politics, is thus established.

Digitized by Google

Three-fourths of the members of the new County Councils will be elected by ballot in the same way as members of Parliament are elected. A probable forestalling of the triennal parliament is proposed, for the Councils are to be elected in the first instance for three years. Thereafter one half of the members will retire every three years. Some such proposal as this has been made for tenure of Parliamentary membership, and this suggests the reflection that these County Councils may not inexpediently be utilised for experimental purposes. Proposed methods may be taken tentatively in one of them, and then if they were found practicable they could be adopted by the others or by Parliament. Such a course might save much waste of time, and save also delayed reforms, through fearful and sometimes groundless anticipations of their supposed impracticability. The extent of area to be comprised in the new counties would of course vary greatly; but the numbers of the population would approximate to equality. The great towns in England would form counties with separate councils. Manchester, Liverpool, Birmingham, Leeds, Sheffield, Bristol, Bradford, Nottingham, Hull, and Newcastle will each be a county possessing its council. A vast number of questions which have frequently been the subject of special attempts at legislation will be in some degree settled by the measure. The partial re-construction of the government of London, for example, will form an integral portion of the scheme. London will no longer be divided among the counties of Middlesex, Kent, and Surrey, but will form a county by itself. The County Council of the new London thus created will absorb the functions of the Metropolitan Board of Works. Although the police government of London will still remain in the hands of the Home Office, this absorption of the Board of Works in the new County Councils is a great step towards the re-casting of metropolitan government. The licensing question is dealt with also by the proposed measure. The granting of licenses will, under it, be part of the business of the County Councils, and will therefore be immediately controlled by popular election. The existing provisions for the granting of licenses are altered under the Bill, mainly in the direction of increasing the power over licenses. The principle of compensation for the refusal of licenses is not only accepted in the Bill, but is regarded by the Government as vital to the existence of the portion of the measure dealing with the licensing question. Compensation involves revenue from some source, and the source from which this is to be drawn is an increase of 20 per cent. in the license duties, payable by spirit dealers. Accompanying this devolution of power to the Councils, the Bill proposes to give them an increased grant from the Exchequer. A sum of £5,600,000 a year will be handed to them by Government, and the existing grants in aid, amounting to £2,600,000, will be discontinued.

The whole scheme is conceived on the most comprehensive lines, though the clear enunciation of the principle of direct popular representation is modified slightly, but not altogether prejudicially, by the provision that three-fourths of the membership of the Councils are to be elected by the general electorate, and one-fourth is to consist of selected members, the selection being made by the Council. It is to be noted that all the provisions of the Bill are in the direction of the decentralisation of administration, rather than the decentralisation of legislation. Yet the establishment of County Councils will undoubtedly either prepare the way for this, or obviate the necessity of its adoption. Legislation affecting local interests will hardly be entered into without consulting these local parliaments, and thus even at once their almost direct influence upon legislation will speedily become apparent. The subject of Local Government is rather too complex to found a party cry upon. The arguments for and against are too numerous for the public to take an excited interest in it; thus there is ample ground for Mr. Ritchie's complaint, that there is no public demand for the measure. Yet there is none the less public necessity, and the Government are unquestionably to be congratulated upon the skill, boldness, and open-mindedness with which they have approached this difficult practical question.

Petroleum.—A gradual but definite change is coming over the petroleum industry in Hungary. The principal features of the situation during the past year have been the increase in traffic with petroleum in tanks both from Trieste and Fiume, the greater production of petroleum in Roumania and Galicia, and the almost complete cessation of the imports of American petroleum. Of refined oil only Caucasian brands are now imported; but the imports of crude oil both from Baku and from Roumania have increased, and more oil is now refined in the country. There have been some experimental bore holes sunk in Marmaros, Murakoz, and Peklenieza; but no definite results have as yet been obtained to show whether Hungary is likely to become an important petroleum country. In Transylvania a new company has been formed under the title of the Transylvanian Petroleum and Refining Company, with head quarters in Kronstadt.

PROPOSED STEAM BOILER LEGISLATION.

In our issue of the 17th February, we drew attention to a Bill that was brought before Parliament last year for dealing with the supervision of engines and boilers, entitled the "Steam Engines and Boilers Bill," backed by Messrs. Burt, Crawford, Abraham, Fenwick, Pickard, and Dyke-Acland; the object being to compel all boiler attendants to pass an examination before, and to receive a certificate from, the Board of Trade. As then pointed out, this Bill was a revival of a similar measure rejected on a second reading some time before, and although we thought there was little probability of its being again brought forward, we find that Mr. Fenwick, Mr. Wm. Crawford, Mr. Burt, Mr. Wm. Abraham (Glamorgan), Mr. Pickard, and Mr. Arthur Acland have again prepared and brought in a Bill entitled "The Engines and Boilers Act, 1888," with a similar purpose, and to extend to the whole of the Kingdom. Nothing appears to have transpired in the meantime, or any additional evidence obtained showing the necessity for such a measure.

The leading provisions of the new Bill are: (1) Every engine or boiler in the United Kingdom must be placed and kept under the supervision of an attendant holding a certificate of qualification under the Act; the number of engines or boilers under one attendant to be prescribed. (2) Every user shall keep a register containing particulars of every engine or boiler owned, name of attendant, and other information, to be produced for the inspection of any examiner under the Act, factory inspector, Court, or person nominated by the Board of Trade. The penalty for default of any part of provisions I. and II. is not to exceed £50. (3) Certificates of qualification *(a)* will be granted to persons passing examinations provided by this Act, and *(b)* to persons who have had charge of an engine or boiler two years previous to the 1st inst. A certificate obtained from the Board of Trade under the Merchant Shipping Acts will be recognised as satisfactory. (4) The Board of Trade will have power to appoint and remove examiners, fix districts, determine regulations as to examinations, qualifications, necessary fees, &c. (5) Also power to suspend, cancel, or re-issue certificates. (6) Penalty of £100 on examiner receiving fees from applicants. Any person forging a certificate, or altering or procuring the same, is liable to imprisonment with or without hard labour, for a period not exceeding twelve months. For fraudulently using a certificate, a penalty is imposed from £10 to £100.

THE LATE MR. T. E. HARRISON.

By the death of Mr. Thomas Elliot Harrison, which took place suddenly on the 20th instant at Whitburn, near Sunderland, the engineering world has lost one of the most respected and prominent pioneers in railway work. He was nearly eighty years of age, having been born on the 4th of April, 1808, and the day before his death was occupied with traffic arrangements on the North-Eastern Railway, of which he was engineer-in-chief. His apprenticeship was passed with Messrs. W. and E. Chapman, civil engineers, of Newcastle-on-Tyne, and when about twenty years of age he came on the expiration of his time to try to make his way in London. He had a letter of introduction to Telford, who told him he had made a mistake in selecting the profession of a civil engineer, as there were very few who rose to eminence, and the others had little or nothing to do. For a time Mr. Harrison was disposed to think Telford was right, but his subsequent career proved the contrary. In 1830 Robert Stephenson engaged him to take the levels between Wolverhampton and Rugby for the London and Birmingham Railway. He was next engaged on the Stanhope and Tyne Railway, afterwards included in the North-Eastern Railway, and in connection with this he designed the Victoria Bridge, which is 157ft. high. Mr. Harrison had a share in the construction of various other lines in the North of England, and ultimately became the successor of Robert Stephenson as engineer-in-chief of the York, Newcastle, and Berwick Railway. Together with Robert Stephenson he had designed the high level bridge at Newcastle. After various difficulties, the competing lines in the North were amalgamated in 1854 under the title of the North-Eastern Railway Company, with 720 miles of line and £23,000,000 capital, which has now increased to 1500 miles of line and £62,000,000 capital, Mr. Harrison taking a very prominent part in connection with this great system. As engineer-in-chief of the new concern he had control both of the permanent way and of the locomotive department, and among the works carried out by him were the Jarrow Docks, which were opened in 1858, and the Hartlepool Docks. He also designed the railway bridge which has recently been built across the Wear at Sunderland. In addition to his more immediate duties, he acted as consulting engineer to the London and South-Western Railway and other lines. He was elected a member of the Institution of Civil Engineers in 1834, and before this Institution he read several papers. He was elected President of the Institution for the session of 1873-74, and in his presidential address dealt with railway management. Mr. Harrison was a member of the Royal Commission on Railway Accidents appointed in 1874, and he was well known by parliamentary committees dealing with railway subjects. By his death one of the most typical figures of the sturdy North has vanished from the railway world, and his sound advice in engineering affairs will be much missed by those who were accustomed to consult him in matters of difficulty.

PUMPING IN MINES BY ELECTRICITY.

In our issue of the 9th December last we published a paper, read by Mr. Frank Brain, before the South Wales Institute of Engineers, in which he described a pumping plant erected at the Trafalgar Colliery. The capacity of this plant in water lifted exceeds 10 h.p., and at that time this was probably the largest underground electric pumping plant at work in England. Since then, however, further progress has been made in the application of electricity to deep mine pumping, and a plant laid down by Messrs. Immisch & Co., at St. John's Colliery, belonging to Messrs. Lock & Co., is designed to cope with a salt water feed of 5100 gallons per hour, at a vertical depth of nearly 900ft. below the surface. It was decided to raise the water at one lift, and at the rate of 7200 gallons per hour, so that the pumps need only work eighteen hours out of the twenty-four in order to cope with the full quantity of water. The plant consists of a 30 n.h.p. compound semi-fixed engine, by Messrs. Robey and Co., driving an Immisch dynamo of 53 h.p. The armature of this machine is 16in. diam. by 24in. long, and the average current is 66 ampères at 600 volts pressure; but owing to the variation of load in the high pressure pumps, the current varies about 10 ampères up and down from the average. The weight of the dynamo is about 4 tons. The motor, which weighs 3½ tons, is also of the Immisch type, and of 575 volts. The speed of both dynamo and motor is 450 revolutions per minute. The actual horse power in water lifted at 120 gallons per minute is 33 h.p. Thus, the efficiency from the electrical energy supplied by the dynamo to the water actually lifted is 62 per cent., which includes the loss of energy in the circuit, motor, gearing, pumps, and that caused by friction in the rising main. Assuming the commercial efficiency of the dynamo to be 85 per cent., the total commercial efficiency of the plant is nearly 53 per cent. The loss in the cables is 2·5 h.p., whilst 13 h.p. is absorbed by the gearing and pumps, and by friction of water in the pipes. We need hardly say that, with a transmission plant of compressed air, the same efficiency could not be obtained, whilst the erection of high pressure air pipes, or even of the smaller pipes required in a hydraulic transmission plant, must be very much more costly, and involve more labour than the running of cables. To show the speed and facility with which such cables can be laid, Messrs. Immisch inform us that the circuits for this plant were laid in seven hours.

Reviews.

A Text Book of the Principles and Practice of Book Keeping. By Professor A. W. Thomson, B.Sc., Royal Agricultural College, Cirencester. London: George Bell & Sons. 1886.

In these days of depression in agriculture, a correct system of book keeping is almost of as much importance to the farmer as improved methods of cultivation, so that he may have a good idea of the nature of the return made by the different kinds of crops. This is especially true when we find there is a growing tendency to "payment in kind." At one time this system of payment was pretty common in various parts of the United Kingdom, and it certainly seems the fairest to all concerned, as by the system of fixed rents no man can tell what may happen to defeat his calculations. The market values of produce may rise or fall, the price of labour may increase or be reduced, whilst the weather is an important factor in all agricultural proceedings; and it is unfair that all the risks of these should be thrown on the farmer over a long period of years. Mr. Thomson's book was specially designed to meet the wants of his students in the Agricultural College at Cirencester, where it was adopted with marked success; but, as the principal of that college remarks in the preface, the clear elucidation of principles contained in it will probably commend it to a much wider circle of teachers and students, especially those who are preparing for any public examinations or public offices, as one of the most useful manuals of the science and art of book keeping which have yet issued from the press.

Minutes of Proceedings of the Institution of Civil Engineers. Vol. XCI. 1888.

This, the first volume of "Minutes" for the current year, contains like its predecessors a vast amount of valuable and interesting matter. It commences, of course, with the President's address, a masterly review of the present state of engineering science as compared with that of fifty years ago. There can be no question as to the scientific progress of engineering during the last half century, and as a body engineers have every reason to be proud of their profession. It may, however, be safely asserted that among the hundreds who listened to Mr. G. B. Bruce's address, there were many who looked back with regret to the early and—for the individual—palmy days of engineering, when chipping and filing had not yet become obsolete, when contractors did not act as civil engineers, and when competition had not yet reduced prices almost to the vanishing point. The first paper in the volume before us, is the second part of that by Sir Frederick Abel on "Accidents in Mines." With respect to the connection between atmospheric pressure and explosions in mines, the author considers that gas escapes from goaves or old workings, which are liable to accompany a sudden fall of barometer, constitute an important source of danger in coal mines. These goaves, which are formed by filling up old workings with the rubbish produced in getting the coal, are not always compact, as the *débris* available is insufficient to completely fill all the cavities, and, consequently, there is often plenty of space for gas to accumulate in the interstices in a position where it is inaccessible to ventilation and inspection. This fact was well established by the evidence of many experts before the Royal Commission on Accidents in Mines. The author discusses the question as to the part played by coal dust in causing or promoting explosions in mines. He points out that no less than eighty years ago Mr. J. Buddle, who was at the head of the Newcastle coal miners at that time and for many years subsequently, drew attention, in a published account of an explosion at the Wallsend Colliery, to the disastrous results caused at a distance from the point of first explosion by the combustion of coal dust; and the possibility of accumulated coal dust being ignited by the flame from an explosion of fire damp, was referred to in 1828 by Mr. Robert Bald in the *Edinburgh New Philosophical Journal*. Experiments made at various times and places, more especially those of the Prussian Fire Damp Commission and those carried out by the author at Chatham, seem to prove conclusively that coal dust alone, if sufficiently dry and fine, may produce an explosion when ignited by the firing of a charge. There is no doubt whatever that it is a source of great danger when present with fire damp.

Of all the matters dealt with in his paper by Sir Frederick Abel, perhaps none is of greater interest than the construction of safety lamps, and it seems probable that at no very distant period portable electric lamps will have superseded those now usually employed in mines. The most promising of these hitherto brought before the public appear to be that by Mr. Scharschieff, in which a small primary sulphate of mercury battery is used, and that by Mr. Blumberg, which weighs only 4½lb. and furnishes a light at starting equal to 1 c.p., the luminosity of which diminishes only very gradually, and after eight hours is yet a little superior to that of a Davy lamp. An interesting discussion and correspondence followed the author's paper.

The succeeding paper is that by Dr. Edward Hopkinson on electric tramways, an abstract of which has previously appeared in our columns. The Bessbrook and Newry tramway appears to be the most important work of this kind in England, having a daily traffic of 100 tons of minerals and goods each way in addition to the passenger traffic. It was specified that the electric locomotive should be capable of hauling a gross load of 18 tons, in addition to the weight of the car itself and its full complement of passengers, at an average speed of six miles an hour on the up journey, and a load of 12 tons at an average speed of nine miles an hour. That these conditions were satisfactorily complied with proves that electric locomotion has now advanced beyond the experimental stage, and it is satisfactory to learn that the cost of working does not exceed that of steam traction on a similar line. The discussion turned chiefly upon the relative cost of electric and other modes of propulsion for tramways, and the limits of length and electromotive force up to which it was desirable to employ conductors, and at which it became more economical to use storage batteries.

Among the selected papers is one by Mr. B. H. Brough, instructor in mine surveying at the Royal School of Mines, on "Tacheometry, or Rapid Surveying." The method of surveying designated tacheometry appears to be little used in this country, but is familiar to engineers on the Continent and in America. According to Mr. Brough it was first adopted in Italy as long ago as 1823. It consists in obtaining by a single observation the elements determining the position of every point visible and accessible from a fixed station point. Surveys by this method can be made in one-third to one-fifth of the time required for the older methods, and it is particularly useful in a mountainous country. As regards accuracy, the author states that Signor Porro, a Piedmontese officer, who made many improvements in tacheometry, attained such accuracy in the measurement of distances that his errors never exceeded $\frac{1}{2000}$. The St. Gothard and Simplon lines, and all the railways constructed in Switzerland during the last fifteen years, have been made from plans prepared by means of the topographical stadia, which differs from the tacheometer only in the fact that the micrometer is applied to the alidade of a plane table instead of the telescope of a theodolite. Mr. Brough gives examples of the cost of surveys made by the tacheometer, and a model of the field book employed in this kind of survey. It seems rather strange that "although the best tacheometers are manufactured in London and largely exported," no details should be available of any application of the method in this country. It would be admirably suited for use in the Colonies and India, and generally for preliminary surveys and pioneer work. If our surveyors and engineers are as ignorant of the advantages of this system of survey as the author would lead us to believe, we would recommend them to study his paper carefully.

An interesting account of the equipment and methods pursued in the engineering laboratories of the Massachusetts Institute of Technology, by Professor Gaetano Lauza, will be found in the same volume. Deserving of special mention is the fact that the Fairbanks testing machine of 50,000lb. capacity can be arranged in such a way as to enable full sized beams of timber to be tested for their transverse strength and deflection up to spans of 25ft. It has been found that the actual strength of such beams is only one-third to one-half of that given by calculations based on the constants given by Rankine, Laslett, Trautwine, Rodman, and Hatfield. This the author ascribes to the circumstance that these investigators made their experiments on small pieces, and that the results obtained are not applicable to the sizes occurring in actual practice.

There are in this volume of "Minutes" two papers by students of the Institution, one on "Propelling Machinery of Modern Warships," by Mr. S. H. Wells, Wh.Sc., and the other on "Hydraulic Appliances at the Forth Bridge," by Mr. E. W. Moir. The foreign "Abstracts" with which the volume concludes, contain as usual much valuable material; their chief use is, of course, to direct the attention of those interested to the original source of information, while at the same time giving briefly some idea of the contents.

Patent Cases Decided by the Comptroller-General and Law Officers of the Crown in 1887, together with Some Unreported Cases in the Courts of Law. Edited by Ralph Griffin, Barrister-at-Law. London: Waterlow & Sons, Limited.

We have been favoured with an advance copy of this valuable supplement to the "Reports of Patent Cases" issued by the Patent Office. Mr. Griffin has taken the greatest possible pains to secure accuracy, and has had the advantage of the assistance and collaboration of the best authorities in carrying out his work, which will be of great assistance to inventors and patent practitioners generally. The cases are arranged in their natural order, so that all those which relate to a particular stage are found together, and reference is facilitated. The first case relates to an application for patent in which the title included the words "and analogous vessels." The Comptroller declined to accept the title including these words; but on appeal the Attorney-General decided that in this particular case the words objected to were limited in the specification and claims, and might be allowed. There are ten cases of opposition to amendments of specifications reported. We may quote from the judgment of one of these cases a passage which should be taken to heart by patentees: "I do not intend to give any costs of this appeal; although I have decided in the patentee's favour, I must say that people who come forward with specifications so loosely framed as this one seems to me to be—I express no concluded opinion upon it—must not be surprised if their rival traders are disposed to oppose their getting the amendment which they may be entitled to." Fourteen cases of opposition to grants of patents are reported, from one of which we may quote from the decision of the law officer with respect to a frequently discussed point: "I am of opinion that if a workman is employed by an inventor to make a model for the purpose of carrying out his invention, and the workman suggests improvements in detail of the machine which are adopted in the machine or model as completed, these suggestions are the property of his employer, and the workman cannot afterwards take out a patent for them." The remaining portion of the work is taken up by cases which have not been previously reported relating to actions for infringement.

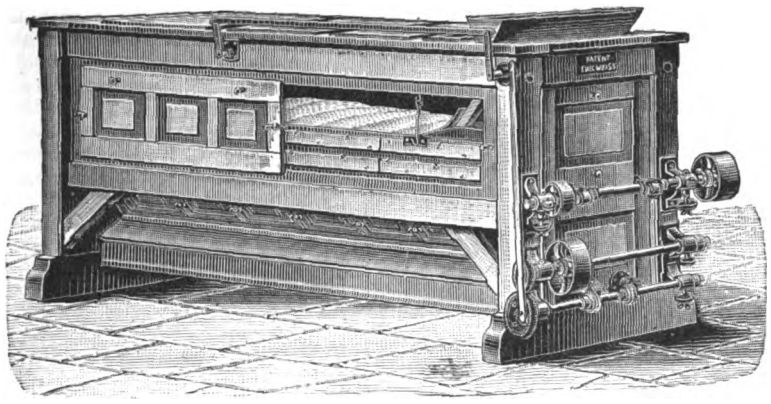
COMMERCIAL EDUCATION IN JAPAN.

The efforts which have been made for some years by the Japanese Government, with the view of furthering both scientific and general education in Japan, are now widely known. Colleges and schools have been established and are well maintained in nearly all the leading industrial districts of the empire, and an activity shown which might well be imitated in many industrial centres in this country. So rapid has been the march of events in Japan, that the whole social fabric has been changed; and classes of men now taking a leading part in the industrial development of the country were, under the former system of government, deprived of the social importance which they now possess. The merchant class is a good example of this change, for after suffering centuries of governmental indifference, this class is now receiving assistance from the Government on every hand. One feature of this assistance is shown in the formation of a large commercial educational establishment in the capital, known as the Tokio Commercial College. Attached to this College is a Commercial Museum, which at present, however, only contains exhibits of native productions. The director of the College, Mr. G. Yano, in a recent pamphlet, states that "The Japanese Government being fully aware of the importance of such an institution to Japan, have founded a Commercial Museum in Tokio, and have decided to devote to its success special care and attention." He also remarks that "Mr. Takashi Masuda, of the mercantile firm of Mitsui & Co., and an influential member of the committee of the Tokio Commercial College, has been requested by the Minister of the Educational Department to collect specimens of merchandise from foreign manufacturers." In order to give effect to the request of the Japanese Minister of Education, Mr. Masuda has forwarded a circular letter to the leading English manufacturers and merchants, a copy of which we publish below. We have also been asked to assist Mr. Masuda in his praiseworthy attempt to extend the range of exhibits and usefulness of the chief Commercial Museum of Japan, because of some knowledge we possess of the technical requirements of the country. We have already taken some private action in the matter; and if we can give any of our readers any information not contained in the following letter, we shall have great pleasure in supplying it:—

(Copy of Mr. Masuda's Letter.)

To English Manufacturers and Merchants.

Gentlemen,—I have the pleasure to state for the information of English firms now doing, or desirous to do, trade with Japan, that there has been established in Tokio, the capital of Japan, a Commercial College and Commercial Museum. The Museum is connected with the College, and both are under the direct supervision of the Government Educational Department. Up to the present, however, this Museum only contains exhibits relating to the productions of Japan, and consequently there is, especially amongst the Japanese commercial community, an earnest desire to greatly widen the scope of the Museum, so that it may contain not only native exhibits, but also exhibits from all the industrial centres of the world.



In order to carry out the object in view, it has been recently proposed to sufficiently extend the present Museum buildings to enable them to contain any samples of foreign productions which may be obtained from manufacturers or merchants desirous of permanently exhibiting their goods or machinery in Japan. The extension of the Museum buildings having been practically decided upon, I am deputed—as vouched for by the Consul's certificate at the foot of this letter—by the members of my Committee to solicit from English manufacturers and merchants contributions for our Commercial Museum. These contributions may take the shape of samples of raw or finished materials, small machines, models, tools, general appliances, photographs, drawings, maps, plans, sketches, catalogues, price lists, or circulars, all of which will be permanently housed, classified, and exhibited in the Museum. In the case of merchantable articles, the current prices should be affixed to the samples.

As regards the exhibits of manufactured goods, it would be of great interest and value if the exhibits were grouped and arranged to show the different stages in the progress of manufacture—that is, from the raw material to the finished product. In order to prevent a repetition of exhibits, intending exhibitors are requested to communicate with the London branch of my firm (Messrs. Mitsui & Co., 1, Crosby Square, London, E.C.), stating the exhibits which they propose to send out, so that they may be informed whether similar exhibits have been already promised.

With the view of making the exhibits commercially valuable to all concerned, it is hoped that exhibitors will forward periodically the revised prices of their goods, and also send early particulars of any invention or improvement in a process relating to the goods or machinery exhibited. Such revised prices or particulars may be sent out direct, addressed to "The Commercial Museum, Tokio, Japan," and will be at once affixed to the exhibits to which they relate. Any exhibits sent will be gratefully acknowledged by the Museum authorities, as they feel that each exhibit will help to make our people better acquainted with the comforts, luxuries, and general material advantages enjoyed by western nations. This increased knowledge of the productions of other nations will lead to an extension of our requirements, and in that way probably enlarge or originate a market for any articles which may be kindly sent for exhibition in our Museum.

THE WEISS PURIFIER.

All packages containing exhibits or catalogues should be sent to our packers, Messrs. Perrott & Perrott, Tenter-street, London, E.C., and be marked **C M**—within a diamond. Any further information will be gladly supplied by the London office of my firm, and in conclusion I confidently hope that this application will meet with a liberal response, and that any exhibits sent may be at once mutually advantageous to our people and to the firms supplying them.

I am, Gentlemen,
Yours faithfully,
T. Masuda,
(Managing Director of Mitsui & Co., Japan),
For the Tokio Commercial College Committee,
Tokio, 15th January, 1888.

Consul's Certificate.

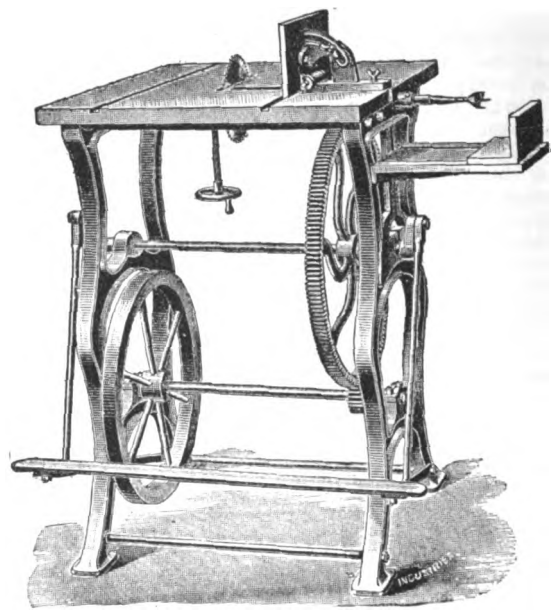
I hereby certify that Mr. Takashi Masuda is one of the Committee of the Tokio Commercial College, and I hope that his application for exhibits on behalf of the College will be entirely successful. I also certify that the Editor of *Industries* is authorised to solicit exhibits on Mr. Masuda's behalf.

M. Arakawa,
Acting Consul for Japan.

London, 5th March, 1888.

THE RECENT STORM IN AMERICA.

(From a New York Contributor.)

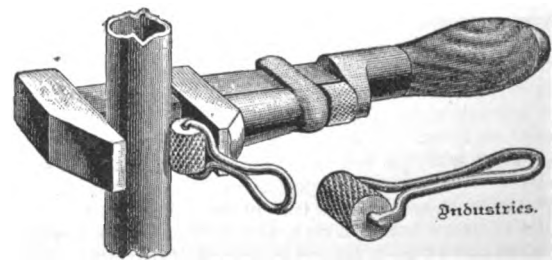


For the first time since steam and telegraphic communication has been established, New York city, the entire country for a distance of about five hundred miles in every direction from the Metropolis, has been practically deprived of all modern means of intercourse for a period of from two to six days. On Sunday, March 11th, at 3 p.m., rain began to fall, which at midnight turned to snow, accompanied by a high wind reaching a velocity at times of eighty miles per hour. This combined storm of snow and wind continued with increasing severity until Tuesday morning, the temperature falling meanwhile from 22° to zero F., with all the characteristics of a western "blizzard." Business was practically suspended on Monday and Tuesday. Steam and horse railways and ordinary vehicles found it impossible to cope with the immense volume of driven snow, which was probably from 18in. to 24in. deep on a level; but in numerous localities lay in drifts of from 4ft. to 15ft. in depth and hundreds of feet in length in city streets and railway cuttings. Telegraph and telephone wires were torn down in many cities and towns by the high wind, and at the time of writing (the 16th inst.), telegrams are arriving in this city by special messengers on the Sound steamboats from various points along the shore of the State of Connecticut, which are as yet isolated from this city by the non-resumption of railway and telegraphic communication. Three thousand telephone circuits are yet incomplete in this city, although every possible effort is being made to restore them. Telegraphic communication has been maintained to a very limited extent with various points by most circuitous routes. For three days press dispatches between New York and Boston have been exchanged *vid* Europe. This has been feasible owing to the fact that the Commercial Company's cable lands at Coney Island, about ten miles from this city, from which point an underground line is laid to the office at No. 1, Broad-street—excepting, of course, the East river crossing. The lines of the long distance telephone company being new and substantially built, have also been utilised for communication with Philadelphia and Boston. Bridgeport, Connecticut, fifty miles away, has been reached by telegraph *vid* Albany and Pittsfield, and the Housatonic Valley, through a region usually more subject to interruptions of this kind than the immediate suburbs of New York. The reliability of all classes of subterranean systems has fairly established itself. Water, gas, pneumatic tubes, and such electric wires as have already been placed under ground, have, of course, been unharmed. The arc lighting wires, while enduring the storm very satisfactorily, have added an element of danger to the general wreckage, and as a precautionary measure the dynamos were not started until the lines had been inspected, as the possibility of fire arising from any cause while the streets and hydrants were buried in snow made the situation extremely critical. The fact that several disastrous conflagrations had occurred within a month pointed to the necessity of exercising every precaution, the fire alarm telegraph system itself being seriously crippled. The loss of life accompanying this storm cannot be ascertained for many days. The whereabouts of missing people cannot be established until all means of communication have assumed their normal condition. Many perished from exposure on Monday in their attempts to reach their families on foot, in order to relieve anxiety as to their welfare. Many railway employés lost their lives through abortive attempts to drive locomotives through the drifts; milk vendors, and others whose duties compelled them to start out at an early hour on Monday before travel was seriously impeded, were in many cases compelled to succumb to the fury of the storm. Amidst all the suffering and annoyance, a determination to patiently endure the hardships of the situation was apparent when it became generally known that business was practically suspended in every direction, and that the situation was simply a holiday cessation of ordinary duties, to be resumed whenever the abnormal condition of affairs could be supplanted by the more ordinary but less sensational methods of civilisation.

THE WEISS PURIFIER.

A machine is now being introduced into this country for the purification of wheat middlings without the use of fan or stive room. The principal advantage in doing away with the latter appliances is a reduction in the risk of fire and explosions, and a consequent saving in the premium to be paid for fire insurance. The machine we are about to describe is the invention of Mr. Emil Weiss, and is illustrated in the accompanying engraving, which shows a perspective view with a portion of the panelling removed. In this machine a somewhat novel principle has been adopted for agitating the material to be treated by air, without, however, using an actual current of air. The middlings are introduced through the hopper seen at the front end of the machine, and fall upon the upper one of two silk sieves, fixed parallel to each other, and with a slight inclination towards the other end in an oscillating frame. According to the results desired, the mesh of the sieves may be varied. The sieve frame receives reciprocating motion from two small eccentrics fixed to the upper horizontal shaft, shown in the engraving. This shaft runs at about three hundred revolutions per minute. The top of the sieve frame is covered in by a cloth, which fits tightly round the edges and round the spout of the hopper: but there is sufficient material in the cover to allow of the oscillation of the frame, and in this way the folds of the cloth participate more or less in the oscillating movement, at the same time agitating the air between the cover and the first sieve. To increase this agitation certain portions of the cover receive a slow up and down movement from wooden rods fixed to a transverse rocking shaft below the cover. This shaft is set in motion by means of the cranks and connecting rods shown in the front of our illustration, power being supplied through an intermediate shaft and a pair of spur wheels. On the shaft to which the larger of the two spur wheels is secured are also fixed two bevel pinions driving archimedean screws, by which the material, after passing the sieves, is propelled to the end of the machine, where it is delivered into sacks. The effect of the two motions imparted to the cloth is to cause an alternate decrease and increase in the air pressure over different portions of the upper sieve, and by this means the branny particles and fluff are kept in motion and gradually lfted along the upper sieve towards the tail end of the machine, where they are delivered by a spout into the bran sack. These light particles are thus kept in motion over the surface of the sieve, whilst the heavier granular meal is allowed to pass through the meshes. The shutters which give access to the interior of the machine are provided with felt joints, and the hopper inlet is fitted with a clapper door and spring to prevent currents of air passing over the sieve when the machine is at work. The purified product, after passing through both sieves, falls into a hopper extending the full length of the machine, but having about its middle a vertical partition by which means the product is divided into two grades. The inventor claims that by this machine bran is completely separated, and to judge from the samples submitted to us, the meal is of a very satisfactory character. One of these machines is now working at the mills of Messrs. Thomas Sugden & Sons, of Brighouse, Yorkshire, and is giving satisfaction. A second machine is being fixed at the mills of Messrs. Sutcliffe & Son, of Bacup. We are informed by the agents of the inventor, Messrs. Whitmore & Binyon, of 28, Mark Lane, E.C., that this type of machine is also finding favour among Continental millers.

IMPROVED TREADLE SAW.



A new circular saw has been brought out by the Britannia Company, Colchester, which is likely to prove a very handy tool for all wood workers who do not possess steam power, as the makers claim for their design a

great ease of working as compared with older patterns. Grooving, dowelling, mitre cutting, and, by means of a separate appliance, scroll cutting may be quickly and neatly done. There is also a boring apparatus provided, which will bore holes up to 2in. with great rapidity.

AMBLER'S ATTACHMENT FOR MONKEY WRENCHES.

We are indebted to our contemporary, the *American Machinist*, for the accompanying illustrations, showing a novel attachment, by which a monkey wrench may be

used for gripping round objects, such as pipes, stud bolts, &c. This apparatus is made by Mr. A. A. Ambler, Springfield, Ohio, and consists chiefly of a small steel roller, which is milled and tempered, and has a wire handle attached to it for convenience of application. There are three points of contact, and the object gripped is not unnecessarily injured. The attachment is so simple that breakage is very improbable, and, not being fastened to the wrench in any way, a slight backward turn disengages it, leaving the wrench available for ordinary purposes. With these advantages, this should prove a useful tool, especially for jobbing work.

AGRICULTURAL AND DAIRY SCHOOLS.

We have on several occasions expressed the opinion that in the cry for improved technical education, the interests of the oldest industry of all, that is agriculture, were not sufficiently attended to. In August of last year, however, the Lord President of the Council appointed a Departmental Commission for the purpose of inquiring into and reporting upon agricultural and dairy schools in Great Britain, which may properly receive Government grants, and to advise as to the department which should be charged with the administration of such grants. That Commission has now issued its report, which will be read with interest by all concerned with agriculture, and of which the following short account will be useful to our readers.

The evidence on which the report of the Commissioners is based is not given; but they state that they have considered the subject under the various heads of (1) the teaching of the principles of agriculture as aided by the Science and Art Department; (2) the practice of dairy farming, including butter and cheese making, breeding, rearing, and feeding of dairy stock; (3) the instruction now available for agricultural labourers, and yeomen and tenant farmers, and for the training of teachers, whether for employment as practical or as theoretical instructors; (4) the agricultural instruction now afforded by universities, colleges, and schools, whether by means of existing endowments, Government grants, or private adventure. The consideration of the evidence has shown the Commissioners that there is a great loss to the country through a want of a wide spread knowledge of the most effective modes of dairy practice, and of certain other agricultural operations, and they are of opinion that an efficient system for supplying this want, and for assisting our farmers to compete with foreign producers, who have the advantage of recently perfected systems of State aided technical instruction, cannot be set on foot without the stimulus of similar State aid in this country. They are, however, averse to launching suddenly into an extensive scheme, but rather suggest that an endeavour be made to carry out cautiously the process of construction; to begin by meeting the most pressing wants, and by engrafting practical agricultural teaching on a limited number of existing schools, to avoid unnecessary building, and to proceed on a well matured system capable of future growth and expansion. Such a system should take into account the interests of all classes directly connected with agriculture, and special provision should be made for labourers, in addition to what is made for tenant farmers and others requiring higher agricultural education.

The Commissioners propose that, in order to prevent schools springing up at random, and unduly multiplying in any locality, and to insure the selection of proper centres, advantage should be taken of the five "produce districts" into which England has for some years been divided by the Agricultural Department for the purpose of estimating the average annual yield. These, with two such districts in Scotland, they propose should form a base for operations, the details of which would be superintended by the local authorities; and they are of opinion that with the exception of a Central Normal School of Agriculture (which they suggest should be provided and maintained by the State), the other agricultural schools now required should owe their origin to local effort, but should be stimulated and assisted by Government.

The Commissioners are strongly of opinion that increased facilities should be given for the study of the principles of agriculture in rural elementary schools, and that gardens, allotments, and farms in connection with them should be encouraged; and they suggest arrangements for bursaries for the scholars, and facilities for the teachers studying practical agriculture. They state, moreover, that the bulk of the evidence taken has demonstrated the fact that district dairy schools are an urgent and pressing need, and can be readily supplied, and they therefore recommend the immediate establishment of seven district dairy schools—one in each of the five "agricultural produce districts" of England and Wales, and two in Scotland, and that an endowment of say £500 a year should be given to each school. The most important recommendation, however, is the establishment of a Central Normal School of Agriculture for Great Britain, to be used chiefly as a training college for teachers of dairy work, at fees of from £40 to £50 a year, to include board, but to which other pupils not intending to be teachers might also be admitted, and that the college should be fully equipped with land, buildings, and staff at the expense of the State. They suggest that it should be established at some central place easily accessible by rail, and that the neighbourhood of Rugby would probably be convenient. They moreover express the wish that the central college should not enter into competition with the already established colleges at Cirencester, Downton, &c.; and they say that if sufficient local effort were forthcoming, a general school of agriculture should be engrafted on to each one of the seven district schools, which would then become active centres of instruction and information in all branches of agriculture in their respective districts. Various other recommendations are made, the most important of which is that the State should make an annual grant of £3,000 to the Agricultural Department, to be expended in such manner as might be thought best, whether in investigation as to diseases of animals or plants, or in prosecuting discoveries in other branches of agriculture. Mr. Mark J. Stewart has issued a memorandum along with the report, founded on the evidence of the Highland and Agricultural Society of Scotland, in which he suggests arrangements suitable for Scotland; but these, and a criticism of the recommendations of the Commissioners, we will reserve for some other occasion.

THE THERMO-DYNAMIC ANALYSIS OF THE GAS ENGINE.*

After remarking that the term "caloric engine" had become narrowed in its application, the author stated that gas engines might be divided into two distinct classes, viz., those engines using water as against those using no water at all. These might be sub-divided into internal and external combustion engines, and again into regenerative and non-regenerative, and into the three following types referred to by Mr. Clerk, and illustrated by small diagrammatic curves of expansion, shown by the author. (1) "An engine drawing into its cylinder gas and air at atmospheric pressure for a portion of its stroke, cutting off communication with the outer atmosphere, and immediately igniting the mixture, the piston being pushed forward by the pressure of the ignited gases during the remainder of its stroke. The instroke then discharges the products of combustion." (2) "An engine in which a mixture of gas and air is drawn into a pump, and is discharged by the return stroke into a reservoir in a state of compression. From the reservoir the mixture enters into a cylinder, being ignited as it enters, without rise in pressure, but simply increased in volume and following the piston as it moves forward, the return stroke discharges the products of combustion." (3) "An engine in which a mixtute of gas and air is compressed, or introduced under compression, into a cylinder, and then ignited while the volume remains constant and the pressure rises. Under this pressure the piston moves forward, and the return stroke discharges the exhaust." Clerk puts the relative dynamic values of these three types as 21, 36, and 45 respectively; but the relative values of the three different types are not properly represented by these figures. The author then dealt with the peculiarities of each class, showing that No. 3 had a higher pressure at times than the others, and had therefore to be more strongly proportioned. So far as steadiness is concerned, No. 2 would be the best, the third type being the most unsteady of the three, the only regulation being obtained by letting the engine make a few strokes empty. Again, Nos. 1 and 3 cannot start without the aid of auxiliary appliances, whereas No. 2, being constructed with a reservoir, was better in that respect, and is the best fitted to take the place of the steam engine. The author then dealt with the question of the injection of steam along with the charge, and said that whenever water is mixed with the charge of air and other dry gases, the combination resulting must be smaller in direct proportion to the quantity used. Thus if we use a charge of dry gas only we get a dynamic value of 2,920,784ft.-lbs. per pound of fuel, while if we use a charge of half dry gas and half steam we get only 1,713,584·5ft.-lbs. per pound of fuel, or lose by the use of steam 1,207,199·5ft.-lbs.—about 40 per cent. Dealing with the water jacket, the loss by incomplete combustion was referred to, and the difficulty of getting accurate figures. With reference to dissociation, Mr. Guthrie was of opinion that the point of dissociation could not be arrived at by experimenting in closed vessels, for the simple reason that it is entirely regulated by pressure, and on a diagram would form a curve somewhat similar to the adiabatic, but reaching far above it. This point was illustrated by a reference to the boiling point of water, which increases with the pressure, and it was urged that if pressure regulates the temperature of dissociation of water, as water, and at certain pressures and temperatures prevents the molecules from flying off from one another, have we not every reason for supposing that a similar condition of things obtains at the higher temperatures, regulating the temperature at which the molecules themselves split up into their elementary atoms? If this be so, he said, then experiments in closed vessels are useless, for the pressure produced by ignition entirely counteracts the dissociation tendency. The opinion of Captain A. Noble was quoted in support of this contention, and it was pointed out that in steel melting furnaces, with the high temperature used, no approach to dissociation was found. It was therefore hardly likely that dissociation would occur in a gas engine at the temperatures obtained; and it was urged that some other explanation of the slow combustion was necessary, a diagram shown by the author being used to illustrate this point, small light letters representing the air both in quantity and dispersion of the atoms, and larger and thicker letters the gas in combination with the oxygen of the air. Supposing the hydrogen, which has a very great affinity for oxygen, to completely combine in a very short space of time—a couple of atoms of the hydrogen only requiring one atom of oxygen. This would not be so with the carbon, which is four times as greedy of oxygen as hydrogen, and may be involved in a double operation. First, that of taking up one atom of oxygen to form carbonic oxide, having done which, it has to seek about, as it were, to find a second atom to form carbonic acid and complete combustion. Now this seeking about must take time, and that time must vary with the amount of commotion going on at the moment. The greater the commotion the more rapid the combustion. In the gas engine of the day the commotion is comparatively small. The charge is first enclosed within the cylinder, commotion comparatively ceasing. Then, by the firing, it is violently but only momentarily agitated, and expansion begins; but expansion is not commotion. It is only a widening apart of the atoms or molecules, their relative positions not necessarily changing. There would be a slight commotion certainly, this slight commotion slowly causing the propagation of inflammation. Agitation after ignition was, in the author's opinion, a very important element in the future gas engine. Summing up, four chief features were stated: (1) Compression, for by it we get greater power in less space, consequently less loss by radiation and conduction, less wear and tear, less cost of production, and should there be anything in the dissociation theory, compression is the antidote; (2) sustained pressure, as in a steam engine, is a feature absolutely essential for many purposes, and is not got in the gas engine of the day; (3) commotion is another very important feature, and this again is not found, at any rate not in that degree necessary for rapid combustion; (4) a hot cylinder and no water jacket is the greatest necessity of all, and seems to be the chief plan for materially augmenting the efficiency of the present engine; for by cold cylinders, it is generally admitted that possibly 50 per cent. of the thermal energy is now lost. In dealing with these propositions Mr. Guthrie described a patented arrangement, the chief feature of which was that of bringing in cool air from the opposite end of the cylinder to that which, so far, has been universally the practice; the cold air port being placed as near the packing rings of the piston as it is possible to arrange. At this point a stream of comparatively cool air is admitted by means of an annular cavity and narrow annular portway, so that the whole of the circumferential surface of the plunger and cylinder is covered with cool air. As the piston moves out, leaving a narrow annular cavity between the plunger and the working surface of the cylinder, the whole of that narrow annular space is filled with this cool air, effectually excluding dust as well as heat, so that the working surface of the cylinder will be as clean and cool as any steam engine. If the cylinder is prevented from getting hot, it is not necessary to apply the cold water method to prevent too high a temperature. Commotion is only to be obtained by adopting the principle of sustained pressure. Mr. Guthrie said that in his proposed engine he intended to have a separate pump which would compress the air up to the working pressure of the engine, so that there may always be a pressure in the valve chest slightly superior to that of the cylinder, just as in an ordinary steam engine; with this pressure behind the valve the cool annular injection before referred to can be secured, and the water jacket abolished, in addition to which a steady inflow of gas and air during combustion can be obtained. Only in this way can a hot cylinder be used. The admission of gas and air was described, the valve near the piston proper being the air valve, which supplies the cooling injection before described. The air just after passing through this valve is divided into two streams, part is for the purpose just mentioned, and part is taken along a small passage or portway to the hot end of the cylinder to mix with the gas and promote combustion. The valve near the hot end of the cylinder is the gas valve, the portway leading direct to the cylinder in such a way as to cause the jet of compressed gas to impinge upon the jet of cool air last mentioned. The process of one revolution would be this: The piston being at the end, and with no more clearance than that of an ordinary steam engine, both valves would open, perhaps just a slight lead being given to the air valve, so as to fill the cylinder clearance with initial pressure before actual combustion commences. Then the instant the piston begins to move, gas and air will enter together and burn as they enter without explosion. The combustion thus carried on will nearly expand the air and gas without any increase of pressure, for the instant that expansion takes place, the inflow of fresh gas and air is checked, and only as the pressure tends to lower will fresh supplies flow in, burn, and keep up the pressure, so that the action is automatic. The ignition, of course, is spontaneous. The lining of the cylinder being hot, no igniting slide is necessary. Some igniting apparatus will be required for starting purposes until the cylinder becomes hot enough from working; but it is only necessary to form two very small bore holes leading into the ignition portway, the one to be supplied with gas and the other with air, under pressure, direct from the valve chest. Another small opening near these must also be provided, through which the gas and air may be lighted, and once lit up will remain alight until turned off. One small double-way cock, or two small single-way cocks, then, is all the lighting apparatus required, and the same apparatus would be used for warming the cylinder before starting if required. This steady burning and expansion under uniform pressure would go on until the valves shut off the supply, after which expansion under reducing pressure would continue to the end of the stroke, as in the steam engine. A pretty brisk commotion or agitation will be maintained, for during the burning under uniform pressure a jet of flame is projected right across the cylinder, creating a constant disturbance; then, again, there is the flow of air from the annular space surrounding the plunger, which, like an Argand burner, streams out in a tubular form, and impinges against the side of the flame, assisting the combustion, not only by the agitation created, but also by the supply of fresh air for combination with any gas which may have escaped from the first flame unconsumed. Such an engine could be worked exactly as a steam engine, with cut-off and reversing gear.

In the discussion which followed, Mr. Dixon pointed out that the range of temperatures in a gas engine was large, and constituted one difficulty. He thought a hot cylinder was the thing to be aimed at, the experience of triple expansion steam engines confirming this. Like the author, he did not think that dissociation was a practical difficulty.

Mr. John Taylor suggested that the solution of the problem might be found in the use of more powerful explosives.

Mr. Lewis was doubtful whether the lubrication of gas engine cylinders with steam was so harmful as Mr. Guthrie thought. Could not some refractory material,

* Abstract of paper read before the Manchester Association of Engineers, March 24th, 1888, by Mr. H. Guthrie.

Digitized by Google

like asbestos, tightly compressed, be used for cylinder linings? With reference to incomplete combustion, he referred to Professor Harold Dixon's experiments on the velocity of flame, and thought that the speed of chemical combination would be so great that there would be little of the searching about of the atoms to which Mr. Guthrie referred.

Mr. Dempster asked a question as to the effect of using oxygen instead of air, and Mr. Hartley remarked that hot gases should not be put into cold cylinders. He questioned whether the gas engine could be used effectively as an expansive engine, but considered that it was undoubtedly superior as a heat engine provided the energy produced could be utilised. He thought that the unsteadiness at present existing was a great evil, and that the tests should be made by lifting water, and not by the brake.

Mr. Guthrie, in reply, said that one of the points to be remembered was the antipathy of the atoms of any body for each other, thus inducing them readily to combine with others. Fleeming Jenkin had worked for some time at refractory linings; but, unless these were non-porous, the gases got into the pores and blew the lining to pieces. With reference to the admission of cool air, he contended that it produced a useful effect, and added to the efficiency of the engine. All loss of heat could not be prevented, but the greater proportion could, he thought, be obviated. The practical engine was undoubtedly that in which a steady push would be given to the piston at every stroke and throughout it, and not that in which a violent propulsion was given intermittently. With reference to dissociation, the experiments already made proved that it did not occur at higher temperatures than those common in gas engines.

ELECTRICAL STRESS.

At the meeting of the Society of Telegraph Engineers, held on the 22nd inst., a paper on the above subject was read by Professor A. W. Rücker and Mr. C. V. Boys.

Professor Rücker, in introducing the subject, referred to the researches of Ker, Gordon, Quincke, and Röntgen on the stress in dielectrics placed between conductors at different potentials, and mentioned that Professor S. P. Thompson had exhibited a lecture experiment to his classes, illustrating the stress in bisulphide of carbon. The authors did not profess to give any new results, but in view of the importance of a general recognition of the fact that electrical action takes place in the dielectric separating conductors, and not in the conductors themselves, they had devised some experiments which would exhibit these actions to an audience.

We need hardly say that the experiments were carried out in admirable manner, peculiar to both authors, and we regret that it is impossible to convey by description even an approximate idea of the beauty and elegance of these experiments. We can only give in the following the merest outline, but would advise our readers not to miss the opportunity if the authors should read another paper on the subject.

The first experiment shown was the introduction of a slab of paraffin between the plates of a charged condenser in connection with the two pairs of quadrants of an electrometer, showing the increased induction owing to the specific inductive capacity of paraffin being greater than air. That the effect was not due to a film of moisture on the surface of the paraffin acting as a conductor was shown by touching the paraffin, which did not alter the deflections of the electrometer; but when the paraffin was coated by tin plates, though the same deflection was produced in the first place, the needle flew back when this metallic casing was touched. Maxwell arrived at the conclusion that the stress in the medium was of the nature of a hydrostatic pressure perpendicular to the lines of force, combined with a longitudinal tension along the lines of force. A kind of crystalline structure should therefore be produced in the medium, so that we should expect its action on light to be similar to that of a crystal with its axis parallel to the lines of force. It was shown when plane polarised light passing through a glass plate placed between two Nicol's prisms is extinguished by turning the second Nicol, the light is partially restored when the glass is subjected to stress. Some experiments due to Ker on electrical stress in bisulphide of carbon were then shown, with the modification of using long cylinders as conductors in the place of spheres, in order to increase the thickness of the medium, and magnify the effect sufficiently to render it visible when projected on a screen. A glass and wood cell, cemented with shellac, and containing two parallel cylinders immersed in bisulphide of carbon, was placed between two Nicols and traversed by a beam of light parallel to the axis of the cylinders. It was then shown that after extinction had been produced, the light passing through the annular space between the cylinders again became visible, when they were oppositely charged, by means of a Wimshurst machine, showing that the attraction was accompanied by stress in the intervening medium. Two cylinders, connected together, and placed between a pair of metallic plates, also in connection, were then charged, the pair of plates and the pair of cylinders forming the electrodes, and it was shown, as before, that the repulsion between the similarly charged cylinders was accompanied by a state of stress in the medium between them. The existence of stress was then shown in the case of a Franklin's pane, with bisulphide of carbon as the dielectric instead of glass. In a similar Franklin's pane, but containing windows in its lower half, the restoration of light was greater in the upper half, which would be expected on Maxwell's theory; while, if the effect was due to irregularities of action at the edges, there ought to be a greater restoration of the light passing through the lower half. The phenomenon of Newton's rings was reproduced by means of a pair of plates, one of which was plane, while the opposed face of the other was a portion of a convex cylindrical surface, the colours being due to the varying stress in the bisulphide of carbon separating them, the stress, of course, being greatest where the distance separating the conductors was least. Some beautiful chromatic effects were also shown by means of Franklin's panes, with the aid of quartz and selenite plates.

UNDERGROUND ELECTRIC LIGHT WIRES.

In a short article on this subject, published in our issue of the 16th inst., we drew attention to the many failures of underground cables which, according to the paper brought before the Electric Light Convention at Pittsburgh, by Mr. Leggett, had occurred in America, and we then expressed the opinion that if the work had been done in England the results would not have been the same. As a matter of fact, the few underground high pressure cables which have been laid at Eastbourne and other places in England have as yet given very little trouble, and the natural inference is that with good material and workmanship distribution of high pressure currents by means of underground cables is perfectly feasible. In America, the work done in the factory is admirable; material, workmanship, and finish of electrical apparatus as it leaves the makers' hands is everything that can be desired. But the same cannot be said of the way the apparatus is erected and worked, and herein lies the reason why we hear so much of cables failing. In England, central station lighting is unfortunately so far behind America and the Continent that very few data regarding the behaviour of high pressure underground cables are available, and we have to look abroad for information. We have, therefore, requested one of our Milan correspondents, who is an electrician of high standing, and intimately acquainted with central station work, to supply us with information regarding the underground systems used in that town, and the following is the account received:—

Milan was one of the first cities in Europe in which the distribution on a commercial basis of electric light from a central station was attempted. The Milan station has been in continuous operation for nearly five years, and has steadily increased its capacity year by year, maintaining its claim to be the largest electric light station on the Continent. It has passed through various phases of development, supplying at first only incandescent lamps in multiple arc, and then successively adding arc lamps supplied from the incandescent lamp circuits, an independent arc system, and finally the alternate current system. These systems require different types of conductors, with varying degrees of insulation adapted to the different currents and pressures. At first, while the station supplied only incandescent lamps on the Edison two-wire system, the requirements as regards insulation were moderate; but with the application of new systems, operated with pressures of 1500 to 2000 volts, and both direct and alternate currents, new conditions presented themselves, and more particularly in the circuits that were laid underground.

The Milan installation, as at first projected, supplied only Edison lamps from a general underground network, as usually adopted in Edison stations, and in which a constant pressure is maintained by feeders. Edison tubes were at first exclusively used, but on the introduction of the arc lighting system a new type of conductor had to be adopted. The conductors for the supply of the Edison incandescent lamps are all underground, and comprise at present over 13 kilometres (8·1 miles) of Edison tubes (two-wire system) and 1 kilometre (0·6 miles) of Siemens cable. For the series arc lighting the Thomson-Houston system is used, only part of the circuits being underground. For this purpose single conductor, lead covered and armoured Siemens cables are used, and of this type about 6½ kilometres (4 miles) have been laid. A Siemens double conductor concentric cable, having a length of 1·8 kilometres (1·1 miles), supplies a number of incandescent lamps at some distance from the station, on the Zipernowsky-Deri system. We have thus installed in Milan at present a total length of underground conductors amounting to 22·3 kilometres (14·2 miles). These several lighting systems are representative of the various conditions of supply which a well equipped station is called upon to meet, and a few details of the various conductors used, and their electrical properties, may be of interest.

The construction of the Edison tubes is too well known to merit a detailed description. Suffice it to say, that in Milan the two-wire system tubes are used with the lamps in simple parallel. In the underground conductor network the tubes are of two classes—mains and feeders. The former have a constant sectional area of 92 sq. mm. (0·14 sq. in.), and represent a total length of 8 kilometres (5 miles). The feeders have sectional areas varying from 250 sq. mm. (0·386 sq. in.) to 650 sq. mm. (1·02 sq. in.), and lengths varying from 118m. (387ft.) to 690m. (2260ft.), representing a total length of 5 kilometres (3·1 miles) in tube lengths of 6·2m. (19ft.) each. In the case of feeders, the large number of joints which the use of such short conductor lengths entails is not advantageous and not necessary, as feeders have no derived circuits, and run from the station straight out to the point at which they are attached to the distributing mains. These conductors carry currents as high as 400 and 500 ampères, with a pressure of 110 volts, and require to be fairly well insulated, as a short circuit or heavy earth in conductors of such a large sectional area might compromise the regularity of the station service. The insulation resistance between the copper segments is usually higher than the insulation to earth, which in the different feeders, after having been in use for five years, varies from a minimum of ½ megohm up to 150 megohms. Cables are to be preferred for feeders, as they may be laid without intermediate joints, or with a relatively small number of such joints, rendering it less difficult to obtain and maintain a higher insulation resistance than in the case where tubes are used as feeders. For one of the feeders a Siemens single conductor lead covered and armoured cable is used for each pole of the circuit. The cable has a sectional area of 625 sq. mm. (0·96 sq. in.), formed of thirty-five strands of wire, each wire having a diameter of 4·77mm. (No. 7 B.W.G.). The resistance per kilometre is about 0·0253ohm.

The cable is provided with a testing wire, which permits of the application in the station of a voltmeter showing the pressure at the feeder terminals, where they are attached to the distributing mains. The stranded core has an insulation of specially prepared hemp, over which follows a lead covering, which is in turn served with a layer of tarred hemp, and the armour consists of two spiral iron bands wound in opposite directions, and served on the outside with a layer of tarred hemp. The external diameter of the cable is about 2·2in. The cable has a total length of about 1000m. made up of lengths of 100m. each, joined by heavy copper clamps in suitable junction boxes, which are filled with a special insulating compound. The insulation to earth of each pole of the cable has not varied sensibly since it was first laid down some six months ago. This cable has been daily carrying a current of 350 ampères at 110 volts, and the insulation remained constant at about 750 megohms per kilometre of conductor. The cable was delivered in coils of 100m., which were mounted on a drum supported by an axle spanning the ditch into which the cable was to be laid, high wheels on the sides serving to move along the drum while the cable was being unwound.

The conductors (tubes or cables) are laid in ditches at a depth of 25in. to 30in. below the street level, and the cables are unrolled from the drum right into the ditch. The conductor (tube or cable) having been covered with a layer of earth to 3in. or 4in., a rough charred and tarred plank is laid over them, to give warning to any future diggers of the proximity of the conductors, and the ditch is then filled up and the paving made good. This simple expedient of laying a board over the cables has saved them from many a pick hole. The Edison tubes were given an extra coat of tar paint before laying in the trenches; but in Milan, which is sadly in need of a complete sewage system, the leakage from the roughly constructed sewage conduits has in many places attacked the iron of the tubes. The streets are built up over the *débris* of the habitations of past generations, and the soil in such localities would in time have ruined the tubes. To effectually preserve the 2000 tubes laid in Milan from becoming corroded to an extent that might in course of time endanger their insulation, it was decided to protect them with a layer of asphalt. The tubes as they lay in the ditch were scraped free from the attached earth, and a tarred wooden box slipped around them, leaving a space of 4in. between the tubes and the sides of the box. Into this space was poured an asphalt in a semi-liquid state, and consisting of two parts of fine sand to one part of tar, forming a durable and perfect protection. Some tinned wrought iron gas pipes that were laid in Milan thirty-five years ago, and protected with a layer of similar

Digitized by Google

composition, were dug up a short time ago, and the tinned iron surface underneath the asphalt was found as bright as when first laid down.

In planning a distributing system for a central station, it becomes exceedingly difficult to provide beforehand for all consumers that may wish to use the current, and the immediate installation of service branches for them all entails a heavy expense. As the electric light station of to-day is called upon to supply current not only for lighting, but also for operating electric motors and for electrolytic purposes, a continuous service of twenty-four hours per day becomes necessary, and the multiplicity of consumers makes it impossible to cut out even for a short time a section of main for attaching new services. It is therefore necessary to use as distributing mains conductors of such a construction that will allow new branch services to be connected while the current is flowing in the mains. As the coupling joints of the Edison tubes are only 6m. apart, they are always near on the one hand or the other to the new service to be connected, and the branches of a T joint for the service conductor can be connected to the coupling joint without interfering with or interrupting the circuit or its connections.

Turning now to the conductors for the Thomson-Houston arc light system, in which the use of a high pressure requires a more perfect insulation than in the case of the 110 volts circuits, the four dynamos installed in the Milan station have each a capacity of thirty arc lamps connected in series, and generate a normal current of 10 ampères. Each dynamo has an independent circuit, and two of the dynamos have only their outgoing wires underground, the return being through an aërial line, whilst the other two dynamos have both of their circuits underground, and in this case the underground conductors are therefore subjected to the full pressure of the dynamos. The underground conductors are all lead covered and armoured cables, with a single No. 8 B.W.G. wire. Two types of conductors have been used, one in which the armouring consists of spirally wound iron wires, and a later type in which (as in the case of the previously described larger cable) the armouring consists of two spiral iron bands wound in opposite directions, the outside diameter of the cable being about 1in. Although these cables have been in continual use for two years subject to a pressure of 1500 volts, no decrease of their insulation resistance has been observed, and no difficulties of any kind have ever been encountered in their use. They were furnished in lengths of 300m., and had an insulation resistance of about 1200-1500 megohms per kilometre, which, after laying down with joints and connections, became reduced to about 600 megohms per kilometre. At this point it has remained. In especially exposed places the cables are laid into tarred wooden troughs, and the space around the cable filled in with cement.

The introduction of the alternate current transformer system called up new requirements, and to meet them we have the double conductor concentric cable. The Zipernowsky-Deri system is used in Milan for the lighting of two theatres that are too far from the station to be economically reached by the network of the Edison system. These theatres are situated respectively at 1200 and 1800 metres from the central station. The concentric cable conveys the 2000-volt primary current from the station to the theatre, where it is transformed into a 110-volt current supplying Edison incandescent lamps. In general construction and protective armour the concentric cable is similar to those already described, with the exception that it has two conductors placed concentrically. The internal conductor is a single wire of 6mm. (No. 4 B.W.G.) diam., and the outer conductor is composed of forty-four strands of wire of 0·88mm. diam. (No. 20 B.W.G.), with a heavy hemp insulation separating the two circuits. At a point 1000 metres from the station, the cable divides into two branches, one of 200 metres and the other of 600 metres, making a total length of 1800 metres. A part of this cable was laid down in June, 1885, and used during several weeks for the lighting of one of the theatres with a temporary installation at the central station, from which an alternating current of 1200 volts e.m.f. was conveyed to the theatre. The following year the cable was used for several months for running a number of Thomson-Houston lamps in the International Milling Exhibition, held in the vicinity of the theatres. Careful tests made before, during, and after these periods failed to indicate any variation in its insulation resistance. Last December, whilst making some experiments on the coupling in multiple arc of alternate current dynamos, the cable was subjected to abnormal conditions, and the insulation suddenly broke down, establishing a short circuit. The defect was immediately located and repaired, and after that the insulation resistance was found to have suffered only a slight permanent diminution. The regular lighting of the theatres was inaugurated a few days later, and has been in continual operation since then, without the slightest hitch, careful daily tests failing to show any permanent change in the insulation resistance. The cable is now carrying a current of 35 ampères, under pressure of 2000 volts, with eighty-five alternations per second. Although conductors carrying high tension currents have not been in use for a sufficient time to make it safe to assert what effect the continual strains to which they are subject may have upon the maintenance of their insulation, the results thus far obtained do not warrant the pessimist views expressed by some American electricians. The electric light is gradually making its way into favour as a general public illuminant, and its future progress largely depends upon the security and continuity of the service without which the general displacement of other illuminants cannot be undertaken. Occasional breakdowns and extinctions were tolerated whilst the electric light was in its experimental stage; but now that stations are projected for the supply of whole districts, with capacities of 20,000, 30,000, and 50,000 lamps, continuity of the service becomes of paramount importance. How closely allied the question of underground conductors is with the future of electric lighting from central stations needs no demonstration, nor do the local engineers claim that this difficult problem has been completely solved in Milan; but what has been done in that direction, thus far, makes it appear probable that no very serious difficulty will be met with in a general system of distribution of high tension currents by means of underground cables.

Notes.

PUBLIC WORKS AT CHERBOURG.

The British Consul at Cherbourg states that the works for the improvements of the outer port and floating basin at that port have been carried on with energy during the past year. The deepening of the outer port is carried on under two iron coffer dams by about eighty men, mostly Italians, who work in relays day and night. Nothing has been done to advance the deep sea pier, though it was commenced some years ago. The railway from Montebourg to St. Vaast and Barfleur, which was opened in 1886, has now been completed, with a branch to Valognes, and is in working order.

INDIAN RAILWAYS.

Reports of the Public Works Department of the Government of India state that the following sections of line have been opened for traffic recently: The Miraj-Belgaum section of the Southern Mahratta system, 85 miles in length; the Warangel-Dornakal section of the Nizam's Guarantced State Railway, 53½ miles in length, and the mineral branch line of Singareni, 16½ miles in length; the Palghat Town extension of the Madras Railway, a length of 3 miles; the Calicut extension of the same line, a length of 9 miles; and the Channrah-Thansi section of the Indian Midland Railway, a length of 95 miles. Sanction has been given for the construction, at the cost of the Darbars of Gondal and Porbandar, of a metre-gauge railway, 69 miles long, from the Dhoraji station on the Bhaonagar-Gondal Railway to the seaport of Porbandar, *viâ* Superi Upleta, Bhayawadar, Jampur, and Wansjalia, and the work of constructing the line is to commence at once.

HARBOUR WORKS AT LLANELLY.

The operations which have been carried on during the last six years in the Burry Inlet, opposite Llanelly and up to Loughor, for the improvement of the navigation, have been eminently successful, as the depth of water in front of the harbour is now nearly double what it was before the commencement of the new works, and vessels of nearly 1200 tons can now enter the harbour. It is anticipated that there will be shortly as much water at this port as at Swansea. The improvement has been effected by constructing a heavy slag bank about three miles in length in such a manner as to divert the main deep water channel which formerly flowed down the middle of the estuary. A new channel, five miles in length, and about 1000ft. broad, has thus been naturally formed so as to flow past the entrance of the harbour. This channel will not have to be kept open by artificial means. The work has been carried out by Mr. W. R. Kinipple, of 2, Westminster Chambers, S.W., and now that it is nearly completed, the Commissioners have resolved to retain Mr. Kinipple's services at a fixed salary as their consulting engineer.

A NEW FLAMELESS EXPLOSIVE.

A new variety of "securite" has been prepared by Herr Schœneweg, which is said to be flameless when exploded, and will, it is expected, be of especial value as a substitute for ordinary blasting powder and other explosives in fiery coal mines. It consists of nitrated hydrocarbons mixed with an oxidising agent such as chlorate of potash and some organic salt which renders the mixture flameless. The substance is not hygroscopic, and is of a bright yellow colour, and can be kept for any length of time without undergoing any change. It cannot be exploded by a flame nor by a hot substance, but only by a detonating cap. Recent experiments at Hendon have proved that the new explosive fulfils the anticipations of the inventor, and we understand that the Flameless Explosives Company have undertaken to introduce it to the notice of mine owners and others to whom an explosive of this nature should be welcome. Its power is said to be equal to that of No. 1 dynamite, and can be manufactured at a less cost. The organic salt which is added to the "securite" to produce this effect, has also the property of rendering dynamite similarly flameless when mixed with it.

WATER SUPPLY.

A prize of 25,000 francs is offered by the King of the Belgians for the best work on the means of supplying good, cheap, and abundant water for large towns, especially for Brussels and suburbs. The essays may be either in print or manuscript, and may be written in either French, Flemish, English, German, Italian, or Spanish. A new edition of a printed work cannot take part in the competition, unless important additions are made to it within the period of the competition, viz., in one of the years 1889 to 1892 inclusively. The essays are to be sent before the 1st of January, 1893, to the Minister of Agriculture, Industry, and Public Works, Brussels.

QUARRY (FENCING) ACT, 1887.

We call attention to the provisions of this short Act, which was passed in the last session of Parliament, and came into operation on the 1st January of the present year. The Act applies to England and Wales, and the term "quarry" includes every pit or opening made for the purpose of getting stone, slates, lime, chalk, clay, gravel, or sand, but not to any natural opening. It enacts that where any quarry dangerous to the public is in open or uninclosed land, within fifty yards of a highway or place of public resort dedicated to the public, and is not separated therefrom by a secure and sufficient fence, it shall be kept reasonably fenced for the prevention of accidents, and unless so kept shall be deemed to be a nuisance, liable to be dealt with summarily in manner provided by the Public Health Act, 1875.

THE POLARISCOPE AND ITS APPLICATION TO BREWING.

At the meeting of the Society of Chemical Industry, held on Monday, the 19th inst., a paper was read on the above subject by Mr. John Heron, in which he described the various polariscopes used for the purpose, including Laurent's, which is most generally employed. In this instrument monochromatic light is used, such as approximates to the D line of the spectrum, and is produced either by placing a salt of soda in the flame of a Bunsen's burner, or by passing light through a glass cell filled with a solution of bichromate of potash. Between two Iceland spar Nicol's prisms is placed a circular disc of glass, one-half of which is covered by a thin plate of quartz cemented thereto, and the indications are read off on a graduated scale; and a small Galilean telescope, placed in the optical system, brings the indicator into focus. The prisms and indicator are so arranged that a disc of uniform tint is first seen; then, by turning the analysing prism in one direction, one-half the disc becomes light, and the other dark; by turning the prism in the other direction, the light and dark halves of the disc are reversed. The liquid to be tested is placed in the optical system of this instrument, and the extent to which it rotates the transmitted rays is read off upon the scale. With some other instruments white light is used, and the disc consists half of a piece of right handed quartz, and half of a piece of left handed quartz. The zero of the instrument is obtained by so arranging the prisms that the whole disc appears to be of uniform purple colour, called "Alpha J." With the slightest motion of the analysing prism to right or left, the uniformity of "transition tint" is destroyed, and by farther motion the different colours come into play on the two halves of the disc. To make observations by these different instruments comparable with each other, the accompanying table is used:—

	Specific rotatory powers of carbohydrates.		Deflection for 1 grm. per 100c.c. in 200mm. tube.		
	AD	AJ	Laurent. Ray D	Soleil Scheibler. Transition tint.	Soleil Dubosc.
Dextrin	195·0	216·0	3·900	11·25	18·00
Maltese	135·4	150·0	2·708	7·81	12·50
Cane sugar	66·5	73·8	1·330	3·84	6·15
Dextrose	52·88	58·6	1·057	2·96	4·88
Levulose	95·65	105·98	1·913	5·52	8·83
Invert sugar	21·3	23·6	0·426	1·23	1·96

The author went at great length into the minute details of his experiments with the polariscope, which, he argued, when properly used, is a trustworthy instrument for the testing of beer. In the discussion, Mr. B. E. R. Newlands (the chairman) and Mr. Salomons said that chemical testing in relation to brewing operations is at present in an unsatisfactory state, and that the experiments of Mr. Heron will be carefully studied.

APPLICATIONS FOR PATENTS.

(The names in italics within parentheses are those of Communicators of Inventions.)

ENGINEERING.

16th March, 1888.

4054. Foster, J. W. ..... Winding yarn from cops.
4057. Turner & Brightmore Application of compressed atmospheric air to motors.
4075. Brogan & Malloch..... Manufacture of figured rolled plate and sheet glass.
4081. White, G. ..... Apparatus for drying cotton.
4083. Neish & Wilson ..... Propulsion of ships.
4085. Wood & Wrightson .... Differential pulley blocks.
4091. Peate, J. ..... Producing a yarn or thread of varying thickness.
4096. Wier, M. A. ..... Type writing apparatus.
4098. Punshon, R. ..... Supporting railway rails.
4102. Johnson, J. Y. ..... Nap raising machines (*Bauche and Bauche*).
4107. Fleischhauer, O..... Weighing machines.
4116. Johnson, J. Y. ..... System of overhead transport (*Torres*).
4117. Hoad, E. A. ..... Apparatus for testing pressure and vacuum gauges.

17th March, 1888.

4121. Proctor, J. ..... Steam boiler furnaces.
4123. Little, A. J. ..... System of drainage.
4152. Gaskell, J. ..... Slide valves.
4156. Hardingham, G. G. M.. Manufacture of twine (*McCormick Harvesting Machine Co.*).
4157. Woolley, G. A. ..... Springs for road vehicles.
4159. Greenway, E. C. ..... Lifeboats.
4160. Bonnefond, N. A. ..... Valve gear.
4166. Redfern, G. F. ..... Closing holes in the hulls of ships caused by collision (*Holmes*).
4168. Lock, C. ..... Couplings for railway vehicles.
4172. Dorman, J. F. W. ..... Printing presses.
4173. Swartzbaugh, J. H., and others. ..... Spark arrester.

19th March, 1888.

18034. Connelly, J. T. ..... Tapping stay bolt holes. (Received 19th March, 1888. Ante-dated 18th August, 1887, under International Convention.)
4176. Kudlicz & Ahlemeyer. Moulding and casting socket and flange pipes.
4179. Garrett, R. ..... Automatic steam cylinder lubricator.
4186. Hargreaves, J. ..... Internal combustion thermo-motors.
4191. Gudland, J. K. ..... Machinery for drilling rock.
4201. Sylbe, P. ..... A combined motor and sectional boiler.
4202. Drummond, G. P. ..... Type writing machines.
4203 Hurst, W. ..... Mules.
4209. Chapman, A. ..... Sugar cane mills.
4216. Abraham, L. ..... Brakes.
4218. Dyson, E. ..... Looms.
4226. Weir, J. ..... Permanent way of railways.
4229. Kempe & Kempe ..... Cutting the surface of textile fabrics.
4231. Taylor, G. ..... Loading and discharging of vessels and waggons.

20th March, 1888.

4239. Hartley, J. W. ..... Potters' wheels.
4246. Aykroyd, E. ..... Smoke consuming furnaces.
4247. Aykroyd, E. ..... Boiler furnaces.
4250. Kirkman, G. ..... An improved traveller employed in ring spinning and twisting of yarn.
4253. Southall, R. H. ..... Machinery for paring the heels of boots.
4254. Gillon, E. W., & others Treating and tempering open hearth or Bessemer steel wire.
4259. Hawley, C. P. ..... Permanent way of railways.
4263. Martin, B. D. ..... The founding of chill rolls.
4266. Gaukroger & Sykes ... Sight feed lubricators.
4268. Fox, C. J. ..... Coffer dams.
4273. Boult, A. J. ..... Increasing the frictional contact between the wheels and rails in railways (*Riels*).
4280. Boult, A. J. ..... Increasing the frictional contact between the wheels and rails in railways (*Ries & Henderson*).
4281. Beasley & Wood..... Lining for furnaces used in the manufacture of iron or steel.
4283. Fletcher & Cawley ... Burglar resisting safes.
4290. Lake, H. H. ..... Pulverising ores (*Wiman*).
4291. Hawley, J. ..... Manufacture of barrels.
4296. Evenstad & Senstad... Machines for making wood wool.
4300. De Coar & Keast..... Railway and tramway brakes.
4304. Cranston, W. McI..... Mowers and hay tedders (*Eddy*).
4306. Haddan, H. J. ..... Magazine fire arms (*Leineweber, Thielepape, & Schrohe*).
4307. Brehmer, H. ..... Machines for cutting pasteboard for the manufacture of boxes.
4308. Krauss & Kumpfmiller Automatic device for letting off waste water from cylinders of steam engines.

21st March, 1888.

4315. Cordes, T. ..... Apparatus for making bullets.
4319. Lumb, J. ..... Speed regulators for steam engines.
4323. Ingham, D. S. ..... Rag grinding machines.
4324. Harrap & Harrap..... Winding, doubling, and twisting yarn.
4326. Shackleton, R. ..... Apparatus for making paper cylinders.
4330. Fuess, P. ..... Dynamometers.
4336. Allmann, J. ..... Fluid meters (*Abegg*).
4337. Isaac, W. ..... "Turn wrest" ploughs.
4339. Carey, A. E. ..... Breakwaters and piers.
4340. Allen, J. J. ..... Feeding sheets of paper to printing machines.
4342. Sanderson, R. W. B. ... Feed water purifier and heater (*O'Brien & Weaver*).
4355. Clark, C. F. ..... Frame pulleys.
4358. Walker, H. C. ..... Hydraulic lifts (*Sélfe*).
4360. Grant, S. A. ..... Ejector mechanism for drop-down guns.
4362. Shilton & May. ..... Bronzing machines.
4363. Thien, K. ..... Preparing moulds for casting pipes.
4364. Haddan, H. J. ..... Safety raft (*Millet*).
4370. Pratt, E. ..... Road or field rollers.

22nd March, 1888.

4378. Leather, J. H. ..... Securing "Garnett wire" to the periphery of cylinders.
4381. Maxwell, J. ..... Railway waggon couplings.
4397. Nicoll, D. ..... Brakes.
4402. Thompson, W. P. ..... Hydrocarbon furnaces (*Porcelain Dental Art Co.*).
4413. Lee & Neale ..... Producing a marbled enamelled surface on cast iron.
4417. Baker, A. ..... Jacks.
4422. Blackstone, E. C. ..... Harvesting machines.
4426. Chatwood, S., & others. Safes, locks, and strong rooms.
4428. Edwards, E. ..... Lubricators (*Elsner-Bourgeois*).
4432. Cito & Funck ..... Lifting jacks.
4433. Low & Smith ..... Apparatus for hardening or tempering projectiles or shells.
4435. Zdziarski, A. ..... Rolling mills.

ELECTRICITY.

17th March, 1888.

4153. King, F. ..... Regulating electric currents.
4171. Freeman, W. S. ..... Electrical governor for motive power engines.

19th March, 1888.

4177. Baines, E. ..... Regulating the tension of telegraph and telephone line wires.
4188. Beaumont, F. J. ..... Arc lamps.
4221. Coad, T. ..... Holders for incandescent lamps.
4222. Holt, H. P. ..... Regulating appliance for dynamo-electric machines.

20th March, 1888.

4240. Yardley, H. B. ..... Burglar alarms.
4270. Fiske, B. A. ..... Regulating electromotors.
4274-5. Thompson, W. P. ..... Storage batteries (*Gibson*).
4277. Boult, A. J. ..... Electro-mechanical movements (*McLaughlin*).
4292. Gilbert, C. E. G. ..... Switch and fuse for electric light.
4294. Myall, A. ..... Commutator for alternating currents (*Judd*).

21st March, 1888.

4317. Mason, J. J. ..... Electric lamps.
4345. Kapp, G. ..... Distributing electrical energy by alternating currents from central stations.

22nd March, 1888.

4393. Freeman, W. S. ..... Control of electric currents.
4425. Charles, P. J., & others Dynamo-electric machines or motors.

CHEMISTRY.

17th March, 1888.

4143. Godefroy, M. L. ..... Treatment of magmas for distillation.
4155. Jones & Jones..... Separating oxides of iron.

19th March, 1888.

4187. Bayley, T. ..... Manufacture of oxide of iron.
4215. Redfern, G. F. ..... Treating decomposed organic substances (*Senorans*).
4217. Thompson, W. P. ..... Colouring substances (*Actiengesellschaft für Chemische Industrie Rheinau*).

20th March, 1888.

4262. Boake, A., & others..... Sodium-meta-sulphite.
4284. Wood, M. R. ..... Mono-carbonate and bi-carbonate of soda.
4286. Croselmire, C. F. ..... Extracting zinc from ores.

21st March, 1888.

4350. Taylor & Struvé ..... Coating with tin and lead.
4353. Buller, E. W. ..... Electric telegraph insulators.

22nd March, 1888.

4418. Abel, C. D. ..... Extraction of gold from ores (*Rotten*).
4430. Atkins, G. J. ..... Treatment of metallic ores.

MISCELLANEOUS.

16th March, 1888.

4055. Smith, A. C. ..... Spring mattresses.
4056. Palmer, J. E. ..... Needle sticking machines.
4060. Doyle, J. E. ..... Bicycles and tricycles.
4061. Howarth, R. ..... Waste preventing stop cocks.
4064. Rylands, D. ..... Stoppering bottles.
4065. Willis & Tuxford..... Locking nuts.
4066. Taylor, J. W. ..... A steam boiler cleanser.
4068. Lancashire, J. ..... Taps and valves.
4072. Müller, J. ..... Miners' safety lamps.
4076. Rawson, T. ..... Bottle stopper.
4077. Hazeland, S. S. ..... Wood workers' edge tools.
4079. Simpson, R. ..... Machine belting.
4080. Samson, A. ..... Set screw.
4086. Bull, J. C. ..... Metallic alloys.
4087. Clifford, W. ..... Safety lamps.
4089. Lansard, J. E. ..... Nut locks.
4092. Weldon, G. ..... Inking rollers in printing machinery.
4099. Newton, J. H. ..... Refrigerating machines.
4101. Wells & Charles ..... Safety lamp.
4103. Street & Ellis ..... Ventilators.
4104. Grant, H. ..... Velocipedes.
4114. Lilley, G. H. ..... Porous blocks for the combustion of liquid hydrocarbons.
4115. Ferranti, S. Z. de ..... Non-return valves or stop cocks.

17th March, 1888.

4122. Gomm, G. R. ..... Reversible copying press.
4126. Zimmer, G. F. ..... Pipes allowing their contents to expand without bursting.
4129. Harrison & Bowing ... Patent fuel.
4133. Bates, H. ..... Internally stoppered bottles.
4134. Pickering, J. T. ..... Automatic fence for lifts.
4135. Rochester, E. ..... Horseshoes.
4136. Pickles & Mitchell ... Preventing the issue of smoke from furnaces.
4137. Tucker, H. C. ..... Velocipede.
4139. Hicks, J. J. ..... Apparatus for ascertaining the specific gravity of liquids.
4144. Harrison, T. ..... Mariners' compasses.
4151. Grant & Francis ..... Tanning leather.
5158. Avery, R. B. ..... Burning gaseous fuel.
4161. McFarlane, G. ..... Spring mattress.
4163. Berger, J. H. ..... Proportional compasses.
4167. Brogden, G. W. H..... Connecting pipes and tubes.

19th March, 1888.

4175. Bunting, S. ..... Manufacture of bottles.
4183. Lloyd, W. ..... Miners' safety lamp.
4195. Justice, P. M. ..... Regenerative gas lamps (*Stein*).
4207. Johnson, S. ..... Portable standard measure and surveying instrument.
4208. Thode, C. W. F. ..... Opening doors by pneumatic or electrical agency.
4211. Rivière, V. ..... Re-tanning hides and leather.
4227. Lake, H. H. ..... Dust collectors (*Smith*).
4234. Wood, A. M. ..... Constructing buoyant cables.

20th March, 1888.

4237. Bell, A. F. ..... Portable tyres for wheels.
4244. Trueman, H. P. ..... Oil lamps.
4245. Moore, D. S. ..... Gas burners.
4249. Smallwood, J. ..... Automatic extinguisher for oil lamps.
4265. Parker, J. ..... Compressing and cooling air.
4267. Rodger, G. ..... Purifying and clarifying water.
4269. Grundig, C. R., & others Dust collector.
4272. Wigzell, E. E. ..... Instruments for taking soundings.
4288. More, J. ..... Aerating liquids.
4289. Dunn, B. S. ..... Gas and air comminglers.
4297. Pistoja, A. G. von B. di Torpedoes.
4303. Cluse & Walters ..... Manufacture of bottles.
4309-10-11. Turpin, E. ..... Explosives.

21st March, 1888.

4314. Garforth & Clayton... Wind bellows.
4321. Robertson, W. ..... Book binders' bordering tools.
4331. Adey, A. W. G. ..... Drying tea.
4334. Cluff, S. J. ..... Improvements in paint and printers' ink.
4344. Postlethwaite, G. R... Hydrocarbon oil burners.
4347. Thompson, H. ..... Rolling tea leaf.
4361. Coltman & Billson..... Manufacture of gloves.
4367. Elphick, O. ..... Water waste preventers.
4369. Booth, W. H., & others. Stoppers for bottles.

22nd March, 1888.

4371. Shelley, W. ..... Water taps.
4372. Foulis & Liversedge... Manufacture of gas.
4383. Dowell, J. S. ..... Buckets.
4384. Swift, H. W. ..... Boiler taps.
4386. Ince, W. ..... Dust collectors.
4388. Rogers & Player ..... Cleaning metal plates.
4398. Pascall, T. G. ..... Evaporating pan.
4401. Higgins, C. M. ..... Forming casts in resinous cements
4405. Higgins, C. M. ..... Bottle stoppers.
4409. Brothers, C. ..... Ventilators.
4411. Williams & Williams. An improved tap.
4412. Ludbrook, S. W. ..... Door for gas retorts.
4419. Boulton, S. B. ..... Preservation of timber.
4423. Malcomson, W. ..... Cooling and desiccating milk.
4424. Parrington, M. B..... Hurdles.
4427. Edwards, E. ..... Miners' safety lamps (*Merlin*).
4431. Henderson, F. J..... Ball valves.

COMPLETE SPECIFICATIONS ACCEPTED.

Persons interested in opposing the grant of the following patents may give notice of opposition at any time within two months after the dates given.

ABSTRACTS OF BRITISH PATENT SPECIFICATIONS.

Compiled from the Published Specifications by W. E. Heys, 70, *Market-street, Manchester.*

ENGINEERING.

Regulating the Level of Water in Boilers.—*J. Murrie, Glasgow.*—Certain improvements are here introduced into the construction of the apparatus described in Patents No. 303 of 1885, and No. 2520 of 1886. The object of the apparatus is to indicate and regulate the temperature and pressure of the water, and is particularly applicable for regulating the level of water in boilers. One form of the indicator is shown in section in the accompanying diagram. The expansion chamber A and the heating chamber B are placed vertically, and the latter is connected near its lower end by a single tube and port G to the boiler D at the point of the lowest water level desired. The tube E connects the steam space in the boiler D with the tube E^1, which leads to the branch E^2 of the valve C^1; the

whistle C^2, giving an audible indication when the water falls below the level of the tube G, is also connected with the tube E^1. The tube E^1 is also in communication with the top of the heater B, and the taps H L are fitted in the tubes E E^1 for the purposes of testing the working of the apparatus from time to time. The cock B^1 on the top of the heating chamber B allows the testing of the circulation of fluid within it. The action of this apparatus is as follows: On the water falling below the tube G, the steam enters and displaces the whole of the water in the upper part of B, and suddenly heats the fluid contained in the vessel A. The vapour thereby generated in the upper part of A presses down the liquid in the chamber of the diaphragm C, which being deflected outwards depresses the lever F, and raises the rod and bell crank lever F^1 F^2. The valve C^1 is thus opened, and the steam enters from the boiler through the pipes E E^1 E^2, and sounds the whistle C^2. Four claims are made for this apparatus and for several modifications.—No. 1770. February 4th, 1887. 8*d.*

Looms for Cutting Pile Fabrics.—*J. Oswald, Manchester.*—A new cutting motion for cutting the pile in the manufacture of plush, &c., is introduced by this invention for the object of saving labour. A knife extends horizontally from one side of the fabric to the other, and is caused to reciprocate in a curvilinear path. This curved path is obtained by means of a series of curved slots in the knife, through each of which passes a stud fixed to the frame. The reciprocating motion is effected by connecting the end of the knife to a revolving crank pin operated by bevel gearing on one of the shafts of the loom. Two claims are made for the employment of the reciprocating knife guided in the way described.—No. 7301. May 19th, 1887. 8*d.*

Grinding and Crushing Mills.—*W. N. Nicholson & W. Mather, Newark, Nottingham.*—This invention relates to the rollers of grinding and crushing mills, which are made up of a series of discs placed upon a square shaft. The discs are made to interlock with each other by lateral projections being formed upon the face of one disc, and recesses being made in the face of the disc next adjoining. The projections fit into the recesses, and thus relieve the longitudinal binding bolts from shearing

Digitized by Google

and bending. Instead of the discs being mounted directly upon the shaft, the holes in the discs are increased in size and a bushing is fitted in the hole, and the shaft passes through the centre of the bushing. By these means the discs have no tendency to cut into the shaft. Two claims are made for the lateral projections and for the use of the bushing.—No. 5571. April 16th, 1887. 6*d*.

Gas Engines.—*J. Y. Johnson, London. (La Société des Tissages et Ateliers de Construction Diederichs, Paris.)*—According to this invention, the residual heat of each compression and explosion of the gas is utilised for the purpose of igniting the succeeding charge. The method of carrying out this invention will be seen by reference to the accompanying diagrams. Fig. 1 represents a vertical section of the combustion chamber, and Fig. 2 an enlarged section of the igniting device. The platinum capsule B is held in position by the flange C, which is embedded in the

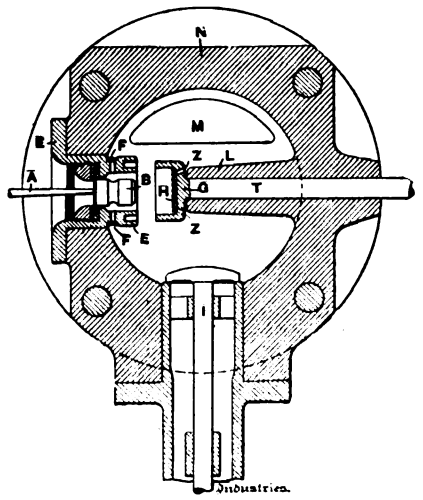

Fig. 1.

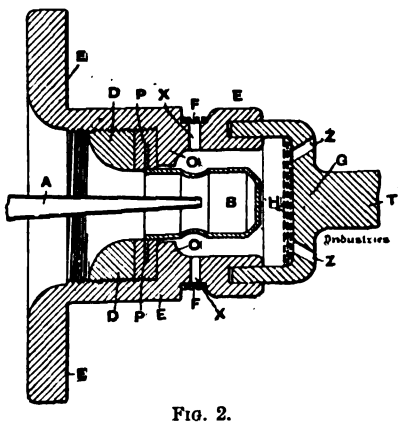
non-conducting packing P. The box E, which holds the screw D and flange C, is fitted in the side of the combustion chamber N. The part of E which projects into the interior of the chamber is provided with holes X covered with wire gauze F. This arrangement prevents the passage of flame, but allows a free circulation of the gas around the capsule. The inner end of the box E is closed by an iron cap G, whose circular edge enters a groove in E, as shown in Fig. 2. The cap G is attached to the end of the rod T, which slides in a tubular socket sleeve L. The wire gauze H protects the holes Z, in the same way as the gauze F protects the holes X. The lower part of the chamber N is provided with two valves I, one of which is shown in Fig. 1, for the admission and exhaust of gas. In working the apparatus, a reciprocating



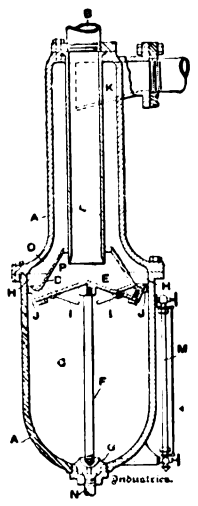


Fig. 2.

motion is given to the cap G by the rod T, in such a manner as to uncover the capsule B at the moment when the explosion is to be produced. In starting the engine when the capsule is cold, a blow pipe A is introduced into the box E, and the capsule is soon heated to incandescence. The gases circulating round it become ignited, and when the cap G is removed from its seat the flame is communicated to the gases in the chamber N, and the first explosion takes place. When the engine has commenced running, the blow pipe is removed, and the ignition of the succeeding charges is produced automatically by the waste heat of the preceding explosion keeping up the incandescence of the capsule. Five claims are made for the igniting device as described.—No. 5095. April 5th, 1887. 8*d*.

Carding Engines.—*W. Cunningham, Selkirk.*—The object of this invention is to make better provision for straightening and laying the fibres on the doffer. A small roller is placed in contact with the doffer, preferably underneath it, and in proximity to the carding cylinder. The roller is driven with a greater surface velocity than the doffer, so that the fibre is laid in comparatively straight lines on the doffer. The covering of the roller consists of wire cloth, but it may be dispensed with altogether if desired. The inventor claims the combination with the carding cylinder and doffer of a fibre straightening and laying roller, fitted as described.—No. 5666. April 19th, 1887. 6*d*.

Lace Machines.—*J. Jardine, Nottingham.*—The great number of warp beams and the smallness of the bobbins render it difficult to adjust the tension correctly as the diameter of the wound thread diminishes. In order to obtain a more regular tension the inventor makes the usual perforated tension plate laterally movable in a trough-shaped frame. This motion is imparted to the plate by two eccentrics, on which it rests. A disc on the end of the axles which support the eccentrics carries a crank pin. A connecting rod joins the two pins, so that the discs are capable of being moved through half a revolution. The eccentricity is sufficiently gradual to keep the warp threads always in a state of tension. The adjustable plate is held in every position quite as securely as the fixed one is, by the eccentric being the full width of the plate. The plate and the discs may be locked at any time, and the machine may be used as it was before the introduction of this improvement. The inventor claims the method of modifying the tension at both ends of the machine, by making the tension plates movable by means of the mechanism described.—No. 5447. April 14th, 1887. 8*d*.

Steam Traps.—*E. P. Stratton, College Point, New York.*—The accompanying diagram illustrates the inventor's improvements in the construction of steam traps. The shell A is composed of two separable sections of cylindrical form. The steam enters through the tangential opening K, and leaves through the delivery pipe B. The lower section of the apparatus constitutes the water repository C; the water gauge M indicates the quantity of water deposited, and the drainage pipe N is provided for the periodic removal of the accumulated water. The improved deflecting shield D is made of conical form, and extends for a distance above and beneath the lower end of the nozzle L, thus making an annular steam and water passage O and a steam passage P. The lower edge of D is provided with a lip which forms the channel H, and the water carried through O is mostly deposited in it. The channel is provided with drainage tubes I, which pass through the diaphragm E into the trap C. The shield is supported by being centred by means of the projections J, whose ends fit to the diameter of C, while the upright support F holds the shield in its place. The lower end of F is threaded into the webbed casting G, which allows the drainage to take place through the pipe N. The saturated steam is introduced through K into the cylindrical space surrounding the pipe L; the water particles are thrown down by centrifugal action and pass through the orifice O, while the current of steam

travels to the interior of the shield, and thence up the pipe B. The channel H intercepts the downward flow of the saturated steam as it is thrown upon the conical surface and collects the condensed portions. The water is conveyed through I into the trap C, while the drier portions are drawn through the space beneath the channel and above the diaphragm E. The diaphragm also prevents the volume of water contained in the trap from being suddenly carried upwards with the steam in the event of an unusual use of the steam. The inventor makes four claims for the arrangement for producing a centrifugal motion of the steam, and for the disposition of shield and diaphragm, as described.—No. 17808. December 27th, 1887. 8*d*.

Removing Slag from Furnaces.—*W. Hawdon, Middleshrough.*—This invention relates to improvements in the apparatus employed in removing molten slag and scoria from furnaces, and afterwards cooling them and depositing them in suitable receptacles. One or more endless bands of wire rope work over two or more series of wheels, to one of which series a rotary motion is imparted by an engine. Attached to the outer face of the ropes is a continuous succession of cast iron moulds for the reception of the molten material. After the moulds have received their contents, they are made to dip into a reservoir of running water, in which a series of jets of water play on the upper surface of the moulds. The inventor claims the construction of the apparatus, which consists of a series of moulds carried by an endless rope for the purpose specified, and for the cooling of the moulds as described.—No. 14803. October 31st, 1887. 8*d*.

Hydrocarbon Engines.—*W. D. Priestman & S. Priestman, Hull.*—This invention introduces improvements into the construction of the engines described in Patent No. 1394 of 1886 and No. 16,779 of 1886 granted to the same patentees. The valve for regulating and controlling the air and liquid hydrocarbon pipes consists of a four-way valve, which is so arranged that in one position it allows the air and oil to be conveyed to the vapour burning lamp while they are shut off from the main vaporiser. In another position of the valve this communication is reversed; while in a third position the supply of air and oil is shut off from both the igniting lamp and from the main vaporiser. Escape from the petroleum reservoir being thus prevented, the pressure in it may be regulated either by means of a small hand pump or by turning the engine, and so operating the pump which supplies the oil reservoir with compressed air. The four-way valve is furnished with a lever which works in connection an indicator showing the various positions appropriate for the valve. In order to obviate the formation of a gummy deposit in the minute passages of the vaporiser, the vapour chamber is divided into two parts; the first serves as an ante-chamber for the reception of the vapour, whilst the heating of the vapour is accomplished in the second compartment. The division is made by a board of asbestos, which prevents the transmission of heat. In order to facilitate the cleaning of the inlet and exhaust valves, they and their seats are arranged so that they may be bodily removed without disturbing the inlet and exhaust connections, and without breaking the cylinder cover joint. Each valve is mounted on a hollow plug, which is fitted into a conical recess formed in the cylinder cover; a lateral orifice in the plug affords communication between its interior and the inlet or exhaust passage. The inner extremity of the plug is open, and forms the valve seat, while the outer end is provided with a stuffing box and gland. Four claims are made.—No. 5951. April 23rd, 1887. 8*d*.

Steam Engines.—*W. P. Thompson, Liverpool.* (*G. Smith, New York.*)—The construction of the cylinder and pistons will be understood by reference to the accompanying diagrams. Fig. 1 represents a sectional elevation at right angles to the crank shaft, and Fig. 2 shows a cross section in a plane passing through

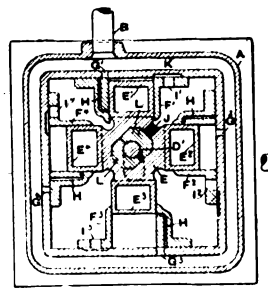

Fig. 1.

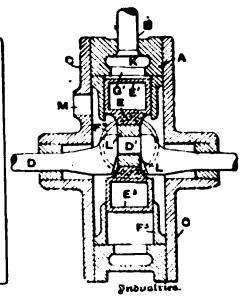

Fig. 2.

the shaft. The outside square box A contains a channel K within it, through which the steam is conducted to the exhaust pipe B. The crank shaft D and crank pin D¹ have motion given to them by the four-sided piston E, which is boxed to the crank pin by the brass box L. The piston has four projecting parts E¹ E² E³ E⁴, which enter the four cylinders F¹ F² F³ F⁴ respectively. The cylinders bear upon the inner faces of the square box, and in their lateral travel act also as valves. The steam is admittted to the interior of the casing through the aperture M, and the pressure of the steam on the surface of the cylinders holds them upon their seats. In the position of the parts as shown in Fig. 1, the full steam is supposed to be entering at the port I⁴. With the further movement of the piston the steam is admitted to the outer faces of the portions E² E³ in succession, and the exhaust ports G¹ G² G³ G⁴ are also opened in consecutive order. The cylinders are provided with the auxiliary exhaust passages H. Each section of the piston travels back and forward within its cylinder through a distance equal to twice the radius of the crank, and also through a similar lateral distance along the side of the box Each point of the piston, therefore, traces out a circular path. This shape of engine is designed with a view to simplicity of construction, and also to obviate the usual dead centre. Three claims are made for the shape of the piston, and for the cylinders which act as valves, as described.—No. 4663. March 29th, 1887. 8*d*.

ELECTRICITY.

Electric Incandescent Lamps.—*A. Featherstonhaugh, London.*—This inventor states that his improvement consists in placing, inside the glass globe of an incandescent lamp, two or more filaments of any kind, close to each other, so that the heat from each reinforces that from the others, and there is less loss of heat by radiation. For these reasons more light is produced by each filament by a given strength of current in each. In carrying out this invention two or more filaments are employed before carbonisation, and are arranged by being twisted round each other in their whole length or in any part of it. The compound element so formed is carbonised in the usual manner, and the subsequent operations of placing it in a glass globe are the same as in ordinary cases. The inventor claims: In all electric incandescent lamps where multiple filaments or wires are used, arranging these filaments or wires so that they are close together, whereby a saving of heat is effected, and there is an increased amount of light produced to what would otherwise be the case.—No. 4549. March 26th, 1887. 4*d*.

Dynamos.—*J. G. Statter, London.*—The object of this improvement is the maintenance of a constant current through a variable resistance, or a constant current when the machine is driven at varying speeds. In carrying these principles into effect it is found necessary to maintain constant the product of the magnetic intensity affecting the armature coils, and the length of the conductors of such coils. With a ring armature constructed in the usual way, the following operations are proceeded with. The brushes are set at the position where no sparking occurs. An exploring apparatus, which consists of a voltmeter with conductors having two small brushes at their extremities, is then employed for obtaining relative indications of the electromotive force of the current flowing through the coils, whose circuit is completed by the explorer. This is done by bringing the brushes in contact with adjacent segments of the revolving commutator. These indications enable the operator to alter the shape of the pole pieces in such a way that when the pole pieces are altered the product of the magnetic intensity affecting those coils of the armature passing under the brushes, into the length of the conductor of such coils directly acted upon by the field magnets, shall be constant. This alteration is effected by boring the pole pieces so as to produce cavities in them. The inventor makes four claims—for the device for altering the position of the brushes, for the pole pieces cut away in the manner described, and for certain specific forms of pole piece for the object of maintaining the current constant at different speeds and through varying resistances.—No. 2825. February 23rd, 1887. 11*d*.

COMBINED DYNAMO AND GAS ENGINE.—*F. W. Crossley, Manchester.*—According to this arrangement the dynamo is mounted on the upper side of the cylinder; on the spindle of the dynamo is a pulley, which is driven by a belt passing round the fly wheel of the gas engine. The cylinder is horizontal, and is placed at one end of the engine frame, while the fly wheel shaft revolves in bearings near the other end. The connecting band is necessarily short, so that in order to tighten it and extend its bearing on the pulley, a lever or slide pivoted to the engine frame carries a tightening pulley that bears against the under side of the band between the fly wheel and the pulley of the dynamo machine. One claim is made for this arrangement.—No. 5833. April 21st, 1887. 6*d.*

ELECTRICAL DISTRIBUTION. — *W. Lowrie & C. J. Hall, London.*—This invention relates to the distribution of electrical energy for the purposes of locomotion. A conductor of small area conveys alternating currents of high tension from the source throughout the primary circuit. One or more low tension conductors of large area are used throughout the circuit in which the tractive force is to be applied. Each of the connections between the two conductors passes through an induction apparatus, such as is described in Patent No. 10765 of 1886. These converters, or secondary generators, reduce the potential of the high tension conductor. As this potential is constant, it follows that the reduced potential of the low tension conductor will be constant also. The secondary circuit may consist of the line of railway or telpherage, or a separate series of wires may be laid for the purpose. Seven claims are made for this system of distribution.—No. 5199. April 7th, 1887. 8*d.*

BRUSHES OF DYNAMOS AND ELECTROMOTORS.—*M. Immisch, London.*—The objects of this invention are to insure a more perfect contact between the brushes and the commutator, and to provide a better arrangement which will allow the electromotor to be reversed. One end of a holder frame is pivoted to the frame of the machine, and from each end of this frame an arm projects outwards, and forms bearings for trunnions on the brush holder. A spring is caused to bear towards the end of each brush, and it can be adjusted so as to regulate the pressure of the brush on the commutator. Two positive brush holders are arranged on one side, and two negative holders on the opposite side of the commutator. One of the positive brushes is connected to one arm of a double armed lever, which is pivoted at its centre to a fixed point of the frame on one side of the commutator, and the other positive brush is connected to the other arm of the lever, so that the two brushes are situated one above and the other below the commutator, and the two holders are connected together with metal. The two negative brushes are similarly carried, and are also connected together by metal. A link connects the two levers, and is provided with a projection to which a piece in the shape of an anchor is pivoted. The anchor moves over a slide formed with a notch at each extremity, and forms the handle for reversing the brushes. When one of its arms engages with the notch, one of the positive brushes is in contact with the upper side of the commutator, and one of the negative brushes with the under side of the commutator. In reversing, the anchor piece is turned on its pivot, thus engaging with the notch at the other end of the slide. This movement causes the double armed levers to rock, and the position of the brushes is altered as desired. The inventor makes three claims for the arrangement.—No. 4032. March 17th, 1887. 8*d.*

CHEMISTRY.

EXTRACTION OF GOLD FROM ITS ORES.—*W. R. Lake, London.* (*A. Vogelmann, Magdeburg.*)—This invention relates to the construction of mercury amalgamators which are used for the purpose of extracting gold from crushed quartz. The annexed diagram shows a vertical section of the improved apparatus. The conical pan A is firmly secured to a flange B^1 at the upper end of the vertical shaft B. The bearings D^1 and C^1 in the upright

standard D and in the base plate C respectively support the shaft B, which is rotated by means of the driving gear F^2 E^1 E. The central part of the bottom of the pan A is provided with a perforated plate L, and the pan A is filled with mercury to a height of a few centimetres above the plate L. The pipe G terminates at the centre of the grating, and is provided at its upper end with the funnel G^1. The conical plate M is fixed in A, and the cone N is tightly fitted to M. The wooden box O is fitted in the shaft B for the collection of the amalgam. The circular trough H is designed to receive the quartz slime which flows over the edge of A. The crushed quartz is mixed with water and fed into the hopper G^1; in its passage through the layer of mercury, during the rotation of the pan, the gold becomes amalgamated with the mercury. The shape of the various parts are so arranged that the slime is kept constantly in contact with the layer of mercury. The amalgam settles into the box O when the machine is stopped, and it is drawn off through the tap P. The rapid rotation, however, while insuring a complete amalgamation, also causes the thickening of the mercury. This defect is obviated in the present invention by conducting electric currents through the mercury. The horseshoe magnets K are placed in the position shown, and the copper ring Q is fixed to the under side of the pan. The current is generated by the rapid rotation of the ring over the poles of the magnets. Between the shaft B and the pan A is placed an insulating layer of felt R. The inventor makes three claims for the employment of the cones M N, which compel the slime to pass in close contact over the surface of the mercury; for the employment of the electric device for the purpose described, and for the general construction of the machine.—No. 16495. November 30th, 1887. 8*d.*

ALKALI MANUFACTURE.—*E. W. Parnell & J. Simpson, Liverpool.*—The object of this invention is to treat gypsum and sulphate of barium so as to render them available as substitutes for the Le Blanc alkali waste in the production of alkali and sulphuretted hydrogen. The sulphate is first converted into sulphide by the method of roasting with carbonaceous matter in a revolving black ash furnace. The subsequent application of the sulphuret is similar to that of the alkali waste as described in Patents No. 381, 1937, and 8440 of 1885, and 47 of 1886, granted to the same patentees. Two claims are made for the process of production and for the application of the sulphides.—No. 5853. April 22nd, 1887. 6*d.*

MISCELLANEOUS.

AIR PUMP FOR REFRIGERATING MACHINES.—*A. Conacher, Augusta, Georgia, U.S.A.*—Fig. 1 represents a vertical section through the pump, and Fig. 2 an enlarged section through the valves. The two perpendicular pump barrels A rest on the chamber B, through which the crank shaft C passes. The tops of the barrels are domed at A^1, and the metal plate F contains

FIG. 1.

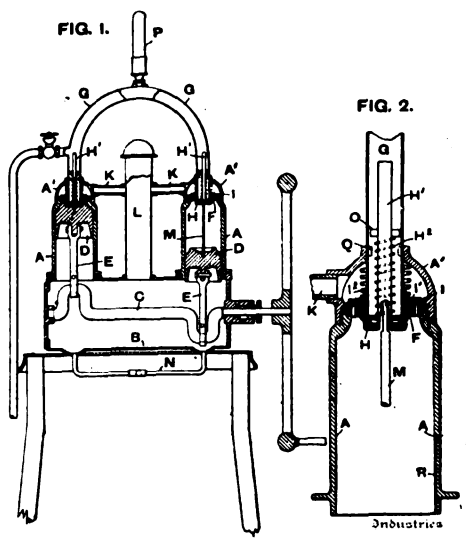

FIG. 2.

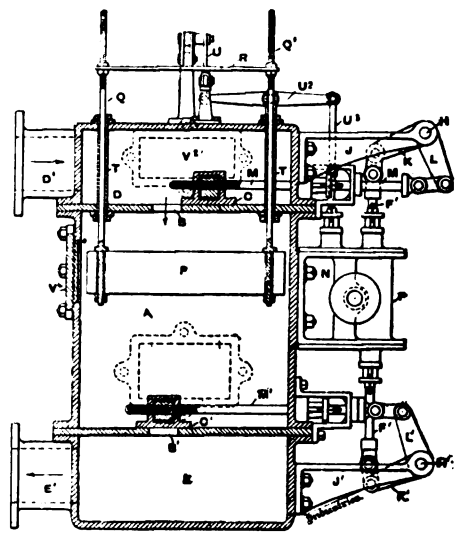


the seats of the suction and discharge valves. The vacuum pipe G is bored into a recess in these plates, and a vacuum gauge is placed at P. The suction valve H is made of a metal plate faced with leather or other material which is not affected by hydrocarbon oils, and its tubular stem H^1 passes through the plate and ascends to a height greater than the length of the stroke of the piston D. The discharge valve I consists of a disc of leather which rests on the top of the plate F, and the discharge pipe K is slightly above the level of F. This pipe leads to a trap cylinder L, which is fitted to the vessel B. In the centre of the piston D is a recess, into which the rod M fits; the other end of this rod enters into the hollow stem H^1, as is shown in Fig. 2 The valve H is held in its seat by a helical spring H^2, and the travel of the suction valve is limited by the stop O, which is fixed to H^1. In operating the pump some hydrocarbon oil is poured in until it fills the whole interior space up to the under sides of the pistons. At each stroke of the piston a minute quantity of oil passes through the groove R, and towards the end of the stroke this oil fills up the space between the top of the piston and the interior of the dome A^1. Every particle of air and vapour is discharged though the valve I. The suction valve H is mechanically opened at the beginning of the downward stroke by the rod M. The springs on M press against the interior of H^1, and pull the suction valve open; but, just before the end of the downstroke, the rod M passes so far out of the stem H^1 that the springs on M cease to act, and the helical spring H^2 then pushes the valve H to its seat; while the cup, forming a raised rim round H, insures the valve seat being covered with oil, so as to prevent any air escaping through the suction valve. The inventor makes six claims.—No. 1181. January 25th, 1887. 8*d.*

SEPARATING REFUSE METALS.—*J. E. T. Woods, London.*—The object of this invention is to separate from refuse metallic substances, such as tin scrap, old cases of tea, preserved meat and vegetable tins, the tin, lead, and antimony from the iron, and to render the latter marketable for soft scrap. The cans are first immersed in a boiling solution of caustic soda or potash, which dissolves the whole of the tin, lead, and antimony. The lead can be separated from the solution in the form of white carbonate of lead, by means of a current of carbonic acid, which is sent through the solution; and the tin can be recovered, either in the form of a crystallised stannate, or it may be thrown down by electric deposition. Iron, copper, or porcelain vessels can be used for carrying out this process; and the rough soap and glycerine in the mother liquors, formed from the fatty matters adhering to the tins, may be recovered after the separation of the metals. The inventor makes one claim for this process.—No. 4434. March 24th, 1887. 6*d.*

ARTIFICIAL LEATHER.—*H. House, Ripon.*—The object of this invention is to utilise leather waste by manufacturing it into a substance resembling leather in texture and composition. The leather scraps are first treated in a disintegrating machine, which reduces them to a fibrous powder. This powder is then mixed thoroughly with a naphtha solution of rubber, and afterwards worked into a dough with a small proportion of glycerine. This material is stamped into thin slabs by a ram, and rolled out into sheets of half an inch thickness. Seven claims are made for this process and for the machinery employed.—No. 5741. April 20th, 1887. 6*d.*

GAS PRODUCERS.—*A. Harris, Middlesbrough.*—When gas producers, which are constructed with solid hearths and tuyeres, and arranged with a bridge over the tuyeres and two entry doors, are being cleaned, the bridge is liable to be knocked down. In order to prevent such an accident, the inventor proposes to employ three doors arranged equi-distantly, and from the walls of the producer to carry up an arch which shall form a second bottom for the producer. A free passage is allowed for the upward travel of the gases, and a solid back of brick work is insured for the poking bar to strike against. The doors are thus comparatively cool, and the bridge forms a substantial mass not liable to be damaged in cleaning. When the nature of the fuel permits, the inventor also employs a movable grate or row of bars opposite the doors, one end of each of which is hinged to the bridge. The opposite ends are supported when the doors are closed, and are allowed to fall when the doors are opened for cleaning. The fuel may thus be held up from the doors and the tuyeres, while the ashes may be shot out when the doors are opened. Two claims are made for the construction of the bridge and doors, and for the arrangement of the set of fire bars.—No. 5530. April 15th, 1887. 8*d.*

FEED WATER MEASURER.—*J. Heslop, Sunderland.*—This invention consists of an apparatus for automatically measuring the amount of feed water supplied to a steam boiler. The accompanying figure represents a vertical section taken through one part of the apparatus. There are two separate similar chambers A, through one of which the section is taken, while the other is placed behind in the drawing. Their capacities are most conveniently from one to five gallons each, according to the size of the engine. Each chamber is provided with an inlet port B and an outlet port B^1, which are opened and closed by the slide valves C C^1 respectively. The water enters from the hot well through the pipe D^1, and leaves for the injector through the chamber E and the pipe E^1. The slide valves are operated by a steam cylinder F and piston rod F^1, whose motion is imparted to the valves by means of the intermediate mechanism K H L M. The links L L^1 and the rock shafts H H^1 are arranged so that both the inlet and outlet ports B and B^1 shall be open alternately. The floats P are suspended within the chambers A, by means of the rods Q Q^1 and cross bar R, from one end of the rocking

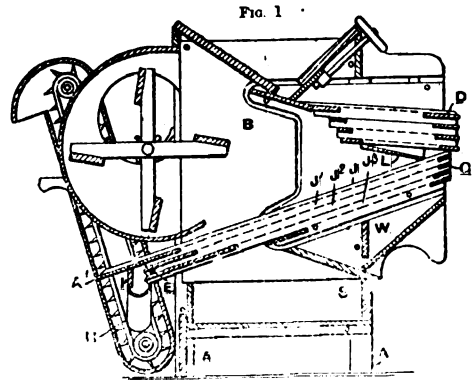
beam S. The rods Q Q^1 pass through the tubes T. The piston valve N, which regulates the steam in F, is operated from the rocking beam S, by means of the system of beams U. The doors V^2 V^4 allow access to the inner parts of the apparatus for the purposes of cleaning. When both floats P are supported by the water in the chambers A, they will be in equilibrium, and the rocking beam S will be horizontal, and the piston valve N will be in a central position, and will therefore cut off the steam from the cylinder F. As soon as one chamber has become empty the float will descend and move the rocking beam in such a way that the valve N will admit steam to one end of the cylinder F; the position of the slide valves will then be reversed. The water will thus enter and leave the two chambers alternately, as will be easily understood. The inventor makes one claim for this apparatus for automatically measuring the feed water.—No. 4958. April 2nd, 1887. 8*d.*

SAFETY FUSE FOR BLASTING.—*F. J. Shand, Cambuslang, Lanark.*—A flexible covering is applied to the main body of the fuse, and is made by felting together a thin layer of cotton wool heated with a solution of rubber. This water proof material is wound helically round the fuse in narrow strips, or it may be wound round the combustible composition, or round the fibrous core. The inventor claims the application of the water proof covering formed and fixed on the fuse as described.—No. 542. January 13th, 1888. 4*d.*

Digitized by Google

GRAIN CLEANING AND SEPARATING MILLS.—*M. Grollimund, Fergus Falls, Minnesota, U.S.A.*—This invention relates to the construction of fanning mills used in separating and cleaning grain. Fig. 1 is a vertical section of the improved mill, and Fig. 2 shows in detail a section of the lower gang of sieves. The frame work A B is constructed in the usual way with a hopper at the upper end. The grain is delivered to the gang of sieves D situated at the upper part of the mill. The vibration of the sieves and the blast of the fan separate the chaff from the grain, which is then delivered upon the uppermost of the gang of vibrating sieves G. The meshes in the series of sieves J J^1 J^2 J^3 are arranged in order of fineness, and each sieve is shorter than the one above it. The detachable diagonal spout A^1 is mounted on the lower end of J for the purpose of concentrating the flow of grain. The cross piece E fits in a diagonal groove in F, and extends somewhat beyond the sides of the sieves through an elongated opening cut in the side of the shoe of the sieve. The

FIG. 1



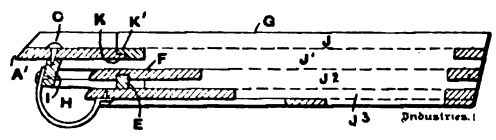


FIG. 2.

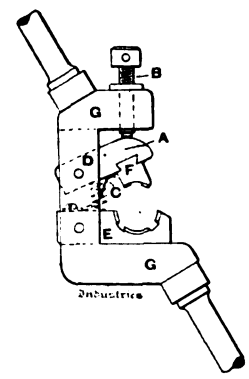
seed falling through this sieve is received in the bin W, and the receptacle S is filled by the grain which falls over its edge. The rest of the grain is deposited in the inclined trough H. The large grain of the first grade that remains on the sieve J is shaken down its face upon the spout A^1, and thence into a suitable receptacle. Smaller grain is carried down the trough H; while the third grade grain is received on the sieve J^2, whence it passes along the cross piece E, and through the opening in the side of the shoe into its receptacle. The grass seed is deposited on the lower sieve of the gang G, and it falls through into the bin W; while the cockle is carried into the receptacle S. The three grades of grain and the grass seeds and cockle are thus entirely separated. If at any time it is desired to mix the first and second grades, the spout A^1 is removed, and the first grade will fall into the trough H along with the second. The inventor claims the combination of the piece E and the opening in the side of the shoe, with the series of sieves and the spout H, for the purpose described.—No. 31. January 2nd, 1888. 8*d.*

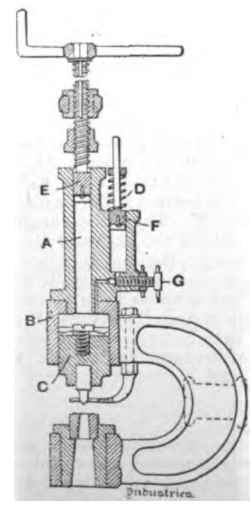
GAS APPARATUS.—*J. Elliott, Ludlow.*—The object of this invention is the construction of apparatus whereby the carbonisation of coal for the production of gas may be carried on continuously without the front door of the retort being opened for the introduction of coal and for the withdrawal of the coke. A hopper is attached to the mouthpiece of the retort; a contrivance of a series of revolving blades is placed on the mouthpiece, and when turned it causes the coal in the hopper to fall into a scoop inserted in the mouthpiece. The scoop is attached to a rod that passes through the lid of the retort, and terminates outside with a handle. To the opposite end of the retort there is also a kind of mouthpiece, from which the ascension pipe rises, and which is provided with a hand hole and lid for cleaning the pipe. The mouthpiece has an opening in its lower part, which corresponds with an opening in a short cylinder that is pivoted to arms attached to the mouthpiece. Above and below the opening in the mouthpiece are saddle flanges made to a true semi-circular curve, so that when the cylinder is brought close against them it may revolve in close contact with the flanges, and so insure a gas tight joint. When the hopper has been charged with coal, a handle in front of the hopper is turned, whereupon coal will fall into the scoop in the mouthpiece. The rod is then thrust in to its full length, and then turned round. The coal will thus be deposited on the bottom of the retort. A second charge is then conveyed to the retort, and so on until there is sufficient coal in. By repeating these operations the coke is pushed to the other end of the retort, and will fall into the cylinder, from whence it falls at intervals into a barrow. Four claims are made for this improved apparatus.—No. 5519. April 15th, 1887. 8*d.*



TUBE CUTTERS.—*A. J. Marquand & S. Williams, Cardiff.*—This invention relates to an improved construction of rotary cutters for severing boiler tubes when in position in the boiler. A tubular boss is made to fit approximately the bore of the tube to be cut, and it has a certain number of holes, aligned in a circle, cut in it. A fixed or movable cutter is provided for each hole. The series of cutters or cutter arms are engaged by a taper mandrel, which can be moved axially through the tubular boss in either direction. For the purpose of effecting this engagement longitudinal slots are cut in the periphery of the mandrel, in order to receive the correspondingly shaped inner ends of the cutters or of their arms. A guide is also provided to regulate the radial travel of the cutters. A movable collar is fixed around the mandrel and tubular boss to bear against the boiler plate, and a nut outside the collar provides for the rotation of the mandrel and cutters by a spanner or other equivalent device. The inventor makes two claims: (1) For the combination of tapered and grooved mandrel and cutters adapted to be engaged by the mandrel; and (2) for the combination of tapered and grooved mandrel, cutters adapted to be engaged by the grooves in the mandrel, tubular boss and guide plate, as described.—No. 5198. April 7th, 1887. 8*d.*

TREATING HIDES.—*J. S. Hooper, London.*—The method here pursued in treating hides is to expose them to the successive attacks of gases from ignited charcoal and sulphur. This process takes place after the hides have come from the lime vat, where the hairs have been removed from them. Twenty to thirty skins are hung in a tight room, in which is placed a vessel containing the substance to be burnt. Twelve hours of exposure to the action of these fumes removes all traces of lime or any taint which may happen to be present in the skin. The hides are then ready for tanning. Two claims are made.—No. 6914. May 14th, 1887. 4*d.*

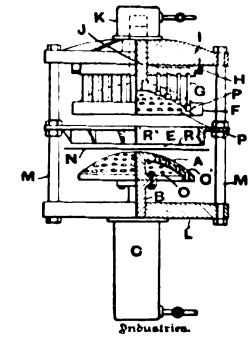
TREATING RHEA BARK.—*G. I. J. Wells & S. L. Howard, London.*—The ribbons of the fibrous material are suspended on rails of wood in rows close together, so as to fill the whole chamber. The chamber is to be made of wood, iron, or lead, and a false perforated roof of porcelain or earthenware is fixed below the real roof, in order to effect a thorough distribution of liquid. The cold liquids to be used are raised to the roof by a pump, and the hot liquids by a vacuum injector, while a fan forces a current of air through the chamber to dry the suspended rhea after its treatment by the sprayed chemicals. Gaseous elements are introduced into the chamber from stills, and a chimney shaft is built in order to take off the surplus gas. In treating the rhea in this apparatus, water is first caused to flow in a continuous rain over the fibre to wash it and free it from dust. Caustic soda or potash is next sprinkled through the false roof. Afterwards the same operation is performed with hydrochloric acid, and another shower of cold water washes away all trace of these agents. The contents are then rained upon by a mixture of soda and oleic acid, during which operation the temperature is gradually raised. A third shower of water finally cleanses the rhea, which is then dried by a current of air. Further bleaching may be effected if desired by applying an ordinary bleaching powder. Five claims are made for the process and apparatus.—No. 2423. February 16th, 1887. 8*d.*



GERMAN PATENT ABSTRACTS.

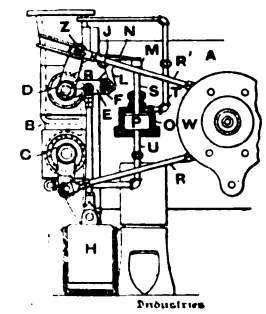
GUIDE SCREW STOCK.—*E. Engels & B. Weselmann, Remscheid.*—This invention represents a novel form of guide screw stocks. One of the dies E is fixed in a suitable manner to the frame G,

while the other die F is attached to an arm A, which is pivoted at D. This arm is actuated by the screw B, while a spring C presses A against B.—No. 42128. April 2nd, 1887.



HYDRAULIC PRESS.—*Karl Prell, Vienna.*—This invention relates to a portable hydraulic punching and riveting machine, actuated by hand. The cylinder consists of two parts A and B, fitted with the pistons E and C respectively. The space between

C and E is filled with liquid. In order to replenish the cylinder, the valve G is opened, and the piston F, actuated by a spring D, forces the necessary amount of liquid into the space between C and E. The valve G is then closed again, and the apparatus is ready for working.—No. 41982. November 3rd, 1886.



UNITED STATES PATENT ABSTRACTS.

BOILER ENDS.—*H. Warden, Philadelphia.*—This invention relates to a new design for the ends of boilers, and to the apparatus for forming them. The end of the boiler is of dished shape, having flat bottomed indentations in it, which are perforated for the reception of the tubes. The accompanying figure shows the machine employed in their manufacture, partly in section and partly in elevation. The frame work M L carries a stationary die E; the movable former A is supported by the ram B, which works in the cylinder C, and the guiding

die F is attached to the ram J. The punches G are fixed rigidly to the plate H, and pass through the annular flat faced dies P in the movable die F. The former A is provided with the perforations O, which are surrounded by the flat die surfaces O^1. The plate to be operated on is placed at N; the die A rises and forms a flange on N; with an increase of pressure the die F gives way, and the punches G stamp the dished plate as required. Nine claims are made for the shape of the boiler end, and nine for the apparatus described.—Nos. 377791 and 377792, dated 14th February, 1888.

VALVE GEAR FOR AIR COMPRESSORS.—*E. Reynolds, Milwaukee, Wisconsin.*—The accompanying diagram shows an elevation of the improved mechanism. The two valves C and D for inlet and delivery respectively are placed at the side of the air cylinder A. The two rods R R^1 connect the wrist plate W with the two valve spindles, and so supply their necessary motion. The weighted arm E is also attached to the spindle of D, and the pin F is pressed by the pivoted catch L, which is provided with

a tail M. The auxiliary cylinder O is fitted with the piston P and the rod S, which extends to a point just below the tail M; the pipes T and U connect the opposite sides of the piston with the air receiver and the air cylinders. The rod R^1 has a slotted end, in which works the pin Z. When R^1 is moved in one direction it closes the valve D, and the catch L keeps the valve shut. When the pressure from the air cylinder reaches a prescribed proportion to that in the receiver, the rod S causes the hook L to release the valve D, which then opens by the weight of the lever E. The spring N serves to press the hook L against the pin F. Ten claims are made for this apparatus for operating the delivery valve.—No. 378336, dated 21st February, 1888.

MANUFACTURE OF WATER GAS.—*R. Boeklen, Brooklyn.*—By the process here described the crude petroleum is fed gradually into the top of a furnace or retort. In its course down the interior of the retort it is subjected to successive degrees of heat; the light vapours are thus eliminated by contact with the superheated steam and the gases which are the result of the decomposition of the steam and oil in contact with the fuel. The light vapours are passed through a heated tile fixing chamber, and the remaining petroleum is subjected to a body of incandescent fuel into which steam is delivered. The gases thus evolved are conducted through the fixing chamber at the same time as the other gases. One claim is made.—No. 378490, dated 28th February, 1888.

The full specifications of the British and United States patents, and the Official Journals of the German Patent Office, from which the above abstracts have been compiled, and the Official Journal of the United States Patent Office, may be seen by subscribers and clients at the Reading Room, Manchester Office of INDUSTRIES, *where also Patent Indexes from* A.D. 1617 *may be consulted. Copies of the British specifications may be obtained on application to* H. READER LACK, ESQ., *Comptroller-General, Patent Office, Southampton Buildings, London, W.C. The published price must be remitted, together with a sum sufficient to cover postage, which may be reckoned at* ½*d. for every* 10*d. or fraction of* 10*d. Remittances exceeding one shilling must be made by Post Office Order.*

COMBINED ENGINES AND BOILERS.

CONSTRUCTED BY MESSRS. RANSOMES, SIMS, & JEFFERIES, LIMITED, AGRICULTURAL ENGINEERS, IPSWICH.

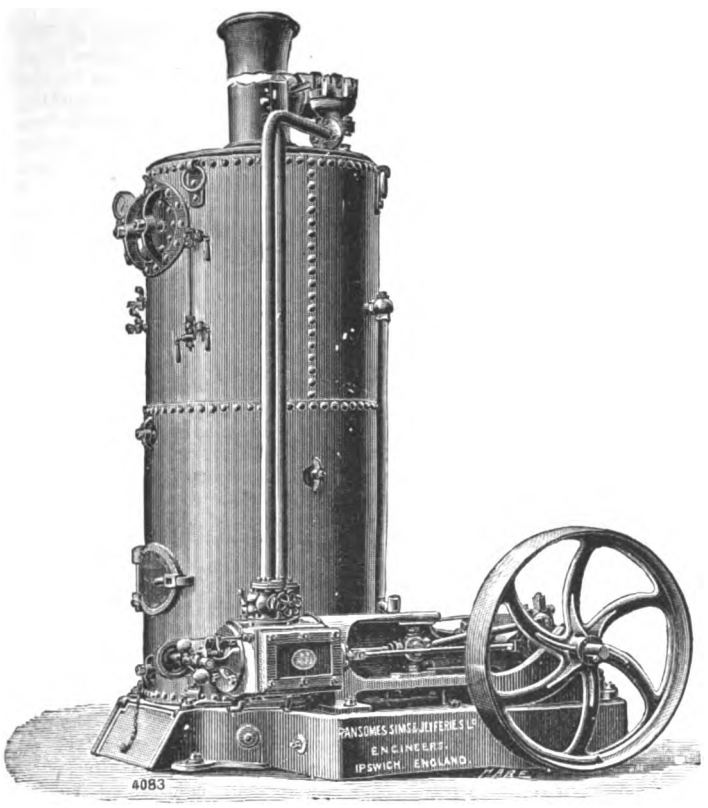

FIG. 1.

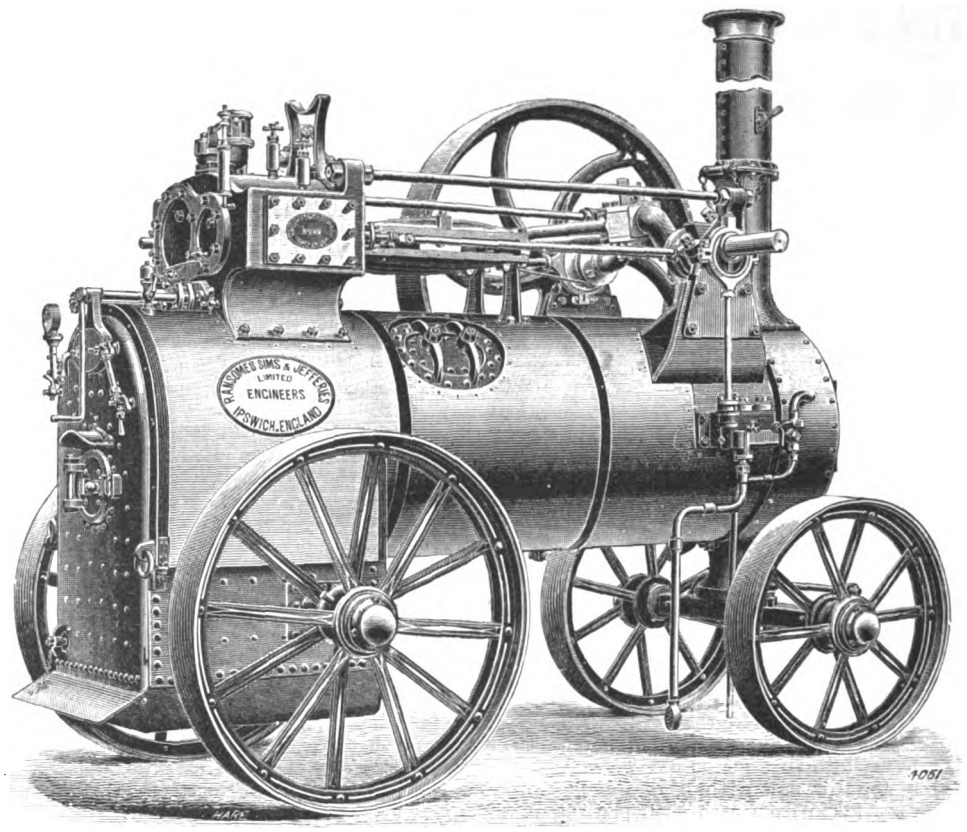

FIG. 2.

COMBINED ENGINES AND BOILERS.

THE accompanying illustrations show different types of engines and boilers, now put on the market by Messrs. Ransomes, Sims, & Jefferies, Limited, agricultural engineers, Ipswich. Fig. 1 shows a horizontal engine with a vertical boiler on the same base plate. The engine is of simple and compact design, and the boiler is one of the cross tube type, and is intended for a working pressure of 80lb. per square inch. The bed plate forms an ash pan and tank for the feed water, which is heated by the exhaust steam. Fig. 2 represents one of the non-condensing compound portable engines made by the same firm. These engines are made from 8 h.p. to 20 h.p. nominal, the cylinders are placed side by side, and made with the outer shell and valve chest in one casting, the inner working barrels are made of special hard iron, the boiler is made of mild steel, and is capable of working at 120lb. per square inch. The crank shaft brackets are of wrought iron and firmly riveted to the boiler, and also stayed to the cylinder by two strong iron tie rods, thereby helping to relieve the boiler of strain. A convenient arrangement is shown in Fig. 3, in which a compound engine is provided with separate boilers. The engine is a 25 h.p. nominal, has a high pressure cylinder 10in. diam., and a low pressure cylinder 16in. diam., each having 18in. stroke; a special expansion valve is fitted to the high pressure cylinder, so that the admission of steam can be adjusted to any point desired. The entire engine is mounted upon a strong wrought iron frame of channel section, which when taken to pieces is in a handy form for packing or shipment. The separate boilers are found more convenient than one large one, on account of the greater facility for transport. They are arranged for a working pressure of 120lb. per square inch, and are constructed of mild steel, with extra large fire boxes for burning an inferior kind of fuel. The connecting steam and other pipes are made of wrought iron, giving lightness and strength. To each boiler is attached a suitable donkey pump, which draws the feed water from a separate tank, and by utilising a portion of the exhaust steam, the water is heated to a considerable temperature before entering the boiler. An injector is also supplied, and in some cases a separate surface heater capable of raising the temperature of the water to boiling point. This is found extremely useful in purifying the water when impregnated with lime or other foreign matter. The workmanship of these engines and boilers is of high class, and the various details have evidently been well thought out, with the object of uniting mechanical efficiency with simplicity of design.

INSTITUTION OF NAVAL ARCHITECTS.

(Continued from page 312.)

The first paper read on Thursday morning the 22nd ult., was by Mr. R. Sennett, R.N., on the

WORKING AND TEST PRESSURE FOR MARINE BOILERS.

The factor of safety was defined as the ratio in which the ultimate strength of a boiler exceeds the working stress, being a somewhat rough and ready method of allowing for stresses, strains, and conditions which can neither be exactly calculated nor otherwise ascertained. It is to a great extent an allowance for want of knowledge, and until comparatively recently marine boilers contained so many unknown quantities that high factors of safety were justifiable. Since the introduction of high steam pressures and steel plates, much greater attention has, however, been paid to materials and the arrangement of details, and the necessity for large factors therefore no longer exists. Thus, in ordinary practice, it has been reduced within a few years from 6 to 8 to from 4 to 5. The present Admiralty rules provide that the stress produced by the water pressure test shall not exceed $\frac{4}{5}$ths of the ultimate strength of the shell of the boiler, which consequently has a factor of $2\frac{1}{2}$ at test pressure. Instead of reducing the working pressure to half the test pressure, it is fixed at 90lb. per square inch below the test pressure, which, Mr. Sennett maintained, affords ample margin for safety. The advantages gained by this arrangement are that the weight and cost of boilers are reduced, and working at higher pressures is not so severely handicapped as under the old regulations. The boilers of H.M. ships "Medea" and "Medusa" are 12ft. in diameter, and are designed for a working pressure of 155lb. per square inch. The water pressure test, in accordance with the new rule, was 245lb. per square inch, and at this pressure the shells

Digitized by Google

have a factor of safety of 2¼. This requires a thickness of shell plates of $\frac{2}{3}\frac{9}{2}$in. By Lloyd's rules they would require to be $1\frac{5}{32}$in. thick, and by the Board of Trade rules 1¼in. The working pressure for these boilers according to Lloyd's rules would be 123lb. per square inch, and by the Board of Trade rules 110lb. The thickness of shell plates required by Lloyd's rules for this working pressure of 155lb. would be by the Admiralty rule sufficient for one of 220lb., and the minimum thickness required by the Board of Trade rules for a steam pressure of 155lb. would suffice by the Admiralty rules for one of 250lb., or more than 60 per cent. greater. The total weight of the shell plates in the boilers of the "Medea" is 52 tons, that is, 14 tons less than would be required by Lloyd's, and 19 tons less than by the Board of Trade rules. The paper concluded by a quotation from Sir F. Bramwell, stating that if the rules for marine boilers were enforced for locomotives, the ordinary working pressure of 140lb. would be reduced to so low a point that the whole railway service of the country would be paralysed.

As was to be expected from the great importance of the question raised in this paper, the discussion on it was of unusual length and importance, the speakers ranging themselves into two opposite parties, one maintaining that the new Admiralty rules are scientific, logical, and safe, whilst the other would not agree to a relaxation of the custom of testing boilers by water to twice their working pressure. The discussion was opened by Mr. Kirk, who regarded this as an exceptionally important paper, the value of which lay in its dealing with an accomplished fact, and not with an abstract proposition. He had previously pointed out that some improvement had been effected by the introduction of high pressure steam, and owing to building by Lloyd's rules rather than by those of the Board of Trade. Subsequently, he had corresponded with the Board of Trade, and urged that for a boiler working at 70lb. pressure there should be a factor of safety of 5; at 100lb., one of 4½; and at 150lb., one of 4. He believed that the factor of safety for higher pressures might be reduced, because the elements that necessitate that factor become of less importance. Bad material is now a thing of the past, as four test pieces are taken from each shell plate at an extra cost of £1 per ton, an expense only grudged because no advantage is allowed to be taken for it. The strains are now well known, and allowed for by the rules both of Lloyd's and the Board of Trade An equally small factor is required for inferior workmanship, especially as the boilers are supervised during their manufacture. It was contended that there is practically no corrosion in a well managed boiler, and if it occurs it is due to the carelessness of the engineers or the stinginess of the owners, and that the whole profession should be handicapped by having to pay for a uselessly strong boiler, and constantly have to carry about so much dead weight, was characterised as a monstrosity. Mr. Kirk protested that the Board of Trade had no right to bother about the duration of the boiler; its certificate lasted but twelve months, and therefore its factor of safety should be lower than that of Lloyd's, who have to consider that the boilers must last many years. In conclusion, he pointed out that the main object of high factors was to guard against such a breakdown as that of the "Livadia;" but as these cracks and defects were in the plates from the beginning, no factor of safety would guard against them.

Mr. Marshall felt the absurdity of keeping a double pressure water test under our better knowledge, and pointed out that Mr. Sennett had taken the Board of Trade rules indirectly into account.

Mr. Cowper maintained that each boiler maker should be allowed to judge for himself and take the responsibility for his boiler. He dissented entirely from the principle that the working pressure should be calculated from the ultimate strength of the boiler. It ought to be based on the elastic limit, because, if that is passed, we have not to deal with the same boiler as we had before. He quoted a case of a mild steel boiler which after several years' work withstood a test of 420lb., and this had restored the confidence that was shaken by the "Livadia." He thought boilers should be tested to double the working pressure, as that was within the elastic limit. He objected to Sir F. Bramwell's comparison of locomotive and marine boilers, as the former can be inspected every day, are half their time in the shops, and thus often last for twenty-four years. When years ago he had argued in favour of surface condensers, it was objected that copper went over to the boiler and corroded it. The fact was that under such pressures the grease turned from neutral to acid grease, and in that way the damage was done.

Professor Kennedy said that all the common sense of this question is certainly not on the side of Mr. Sennett; he had read the paper carefully, and it seemed to him that the proposal was simply this: we require to use high pressures, and thick shells are inconvenient, therefore let us use thin ones. This position seemed analogous to that of people who object to pay their debts, and prefer to write them off. He objected to Mr. Sennett's statement that progress has been owing to modifications of rules, and thought that it ought to be obtained from improvement in designs, and better knowledge of strength of materials. Mr. Sennett's proposition that the boiler should not be tested to twice its working pressure the speaker thought to be a matter of opinion; but he objected to making the working pressure so near the strength according to the hydraulic test, as the two strains are not comparable. The high temperature introduces stresses not present in the water test. Should we, he asked, place a higher strain upon boiler plates than is done upon certain leading parts of engines, such as the crank shaft, &c., when the boiler is subjected to much more uncertain stresses, and when accident would be so much more dangerous? Mr. Sennett said that we can apply exact calculations to boiler shells, but Professor Kennedy denied this, as we have too little knowledge of the resistance of riveted joints. During recent tests he had found materials to be shockingly unreliable; thus in one case of two specimens of supposed equal strength one gave 18 tons and the other 24 tons, and in another case one specimen gave 15 tons and the other 26 tons. Nor do we know how the strains are altered by plates being perforated, and there are local inequalities we cannot estimate accurately at the flanged joints at the ends. The speaker maintained that 28-ton plates should not be subjected to an 8-ton stress, and that boilers are the last things in which the stress should be overdone. In the illustration from locomotives Mr. Sennett was mistaken, as in the Webb engines with 175lb. pressure, or the Worsdell working at 170lb., the stress was only 5¼ tons per square inch with ½in. plates, about which we know much more than we do about 1in. plates; hence locomotive practice does not justify this alteration.

Mr. Stromeyer objected to Mr. Sennett's rules being applied to the merchant service, and pointed out that the choice of this 90lb. pressure was quite as arbitrary as the old standard. He thought a new standard should be fixed, but that the test pressure should not be lower than one and a half times the working pressure. He pointed out that with increased working pressures, and therefore increased temperatures, we approach a dangerous limit in the strength of the steel. He further insisted that a new rule should be more comprehensive, and include high and low pressures, that is, a rule to show how the factor of safety varies for different pressures.

Mr. Daniel Adamson referred to his extensive experience of steel boilers, and said their great advantage was due to the equal strength of steel in all directions. He objected to applying formulæ that act admirably for short boilers, to long or complex ones, and illustrated his point by reference to the bursting of one on the London and North-Western Railway locomotives, in which the disaster was aided by the sudden alterations in temperature, and if a high temperature produced such results with ⅜in. plates, what might be its effect on 1in. plates. In reply to Mr. White he explained that the factor of safety of his own boilers is 5, and he had adopted as much as 7 in some that vary greatly in temperature. He thought both the 90lb. and the rule for double pressure test to be unwise, and he should prefer to see a *pro rata* rule adopted.

Mr. Reynolds, after correcting some loose statements as to the rising of phosphorus in ingots made by the last speaker, pointed out that the great danger of the present paper was from the tendency of the mercantile marine following this lead. He first had suggested constructing boilers of layers of thin plates, and maintained that this principle might well have been used in the "Medea" plates.

Mr. Alex. Taylor, speaking as a shipowner and a member of Lloyd's Committee, thought that few shipowners would care to see the factor of safety reduced, and that they expect their boilers to last at least fifteen years, and would strongly object to having to take up their decks and disarrange the whole vessel every five or ten years. He pointed out that the navy practice and that of the mercantile marine were not closely analogous, as in the latter the engines are worked at full pressure for days and weeks together, whereas in the navy the work is not nearly so constant.

Mr. Parker, the Chief Engineer-Surveyor of Lloyd's, considered the paper dangerous. Mr. Sennett's first proposition seemed to be that the strength of the riveted seam is the test pressure, and 90lb. below that is the working pressure. The speaker referred to his experiments on the elastic limit of steel made during the last year, and quoted Sir F. Bramwell's statement that the elastic limit of a material was usually supposed to be a line which if crossed would destroy the material, but that he (Sir Frederick) did not know what that limit was. The speaker had found that the limit of elasticity of a plate was lowered by working from 14·8 tons to 10 tons, and therefore if Mr. Sennett is trusting to the limit of elasticity he is treading on dangerous ground. We do not know much about the strength of joints, their strength being obtained only by calculation, and the speaker had found in every case he had tested that the strength was below the theoretical value. Further, the steam pressure accumulates when the vessel stops, and this accumulation often reaches 10 per cent. Again, Mr. Sennett made no allowance for corrosion; but to show that such is not an imaginary danger, he exhibited plates which had been reduced to two-thirds of their thickness by this cause. Moreover, the stresses in a boiler vary greatly with the firing; thus at times one part may be at 1100°, and another part at 300°. From all these causes, and remembering that latent defects are always likely to be present, Mr. Parker insisted that a large factor of safety was absolutely necessary, and the adoption of Mr. Sennett's limit would be a serious matter. To show what the result of an accident would be, he referred to the explosion of a steam pipe at Southampton at the working pressure. It had been tested by hydraulic pressure to two and a half times the working pressure, and had a factor of safety of 10. Nevertheless, by one of these latent defects it burst, and killed ten persons. Mr. Parker felt sure that the bursting of a boiler would send any ship to the bottom. He next asked whether the advantage gained is worth the risk, as by adopting the new rule only a small saving in weight was secured. In regard to Mr. Sennett's statement about locomotives, he had certainly been misinformed. Mr. Parker had recently been in correspondence with all the leading locomotive superintendents in the kingdom, and found they unanimously agreed that they would not work below a factor of safety of 5 or 6, whereas Mr. Sennett was adopting one of only 3. A letter was read from Mr. Deane, the manager of the works at Swindon, who was specially emphatic on this point. Mr. Parker concluded by saying that Lloyd's Register would be willing to confer with the owners if any considerable section of them were anxious for a change in the regulations on this subject.

Admiral de Horsey admitted that in the Admiralty everything was sacrificed to speed; but naval boilers would not compare with those in the mercantile marine, which run for days and weeks at the same pressure, whereas in the navy, when such is attempted, the tubes choke, the boilers leak, and everything goes wrong. The surging of the water in the boiler during a gale must try it greatly, and the fate of some of the ships of the navy that had left port and never since been heard of was perhaps to be explained by reference to the boilers.

Mr. Seaton considered himself committed to Mr. Sennett's policy, as he had published the same conclusions years ago. He did not think there was such a difference between the navy and the merchant service as previous speakers had assumed. Though the former did not often require to go at maximum speed for long, they might have to do so. In regard to the corrosion of shell plates, he had examined hundreds of disabled boilers, and less than 5 per cent. were condemned from defects in the shell; and as the plates are 22 to 24 per cent. stronger than the seams, he thought that allowed sufficiently for corrosion. Mr. Parker's argument that we can place greater confidence in ⅜in. plate than in the 1in. plates told more in favour of reducing the thickness than against it. He advocated the hydraulic pressure test to be applied at a temperature of 212°.

Several subsequent speakers objected to the application of this rule to the merchant service, as by it the boilers would probably not last so long nor be so safe. Mr. List and Mr. Jones thought there is little corrosion if the boiler is properly looked after, and Mr. Gray was not alarmed at the limit of elasticity, as he knew of a case in which a boiler had its steam dome blown off, and though the limit of elasticity must have been passed, a new dome was put on, and the boiler had worked well ever since.

Mr. White considered Mr. Sennett's innovation both scientific and safe. Not one of the speakers had consistently assailed his position or defended a test of twice the working pressure, and no one who knew the Admiralty specifications had opposed them. The hydraulic test was not an assurance of safety, but only a test for imperfect workmanship. To get such an assurance, Mr. Sennett proposed to abolish the method of multiplication, and the discussion showed that this has been already done by many of our best engineers in their own practices. Professor Kennedy, with studied moderation, had told them what he regarded as the plain English of their propositions, and laid before them some figures; but though fully admitting Professor Kennedy's authority on that point, he could not attach much importance to them till he knew on what they were based. Mr. White protested that the navy boilers were not the grotesque failures Admiral de Horsey represented. In the days of auxiliary steaming the boilers were subjected to terribly trying conditions; but they have vastly improved with the abandonment of sails, and recently ships were tried steaming continuously night and day for four days in distant parts of the world, and were found to give from 70 to 80 per cent. of their speed on the measured mile.

Mr. Sennett, in replying to the discussion, said he had not intended to attack Lloyd's rules. He protested that it was absurd to maintain a high factor of safety destined to cover unknown quantities when the unknown quantities had one by one been eliminated. Mr. Parker had gone

Digitized by Google

INSTITUTION OF NAVAL ARCHITECTS.

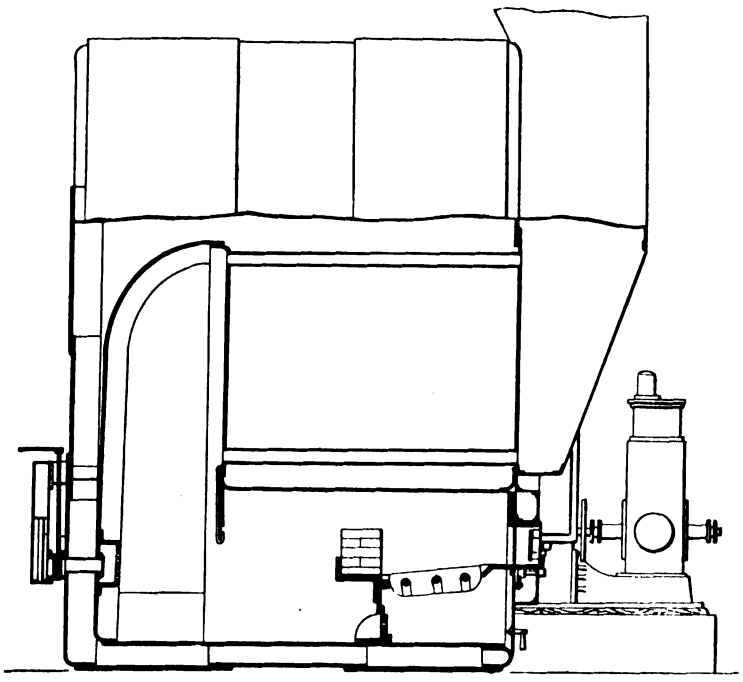

Fig. 1.

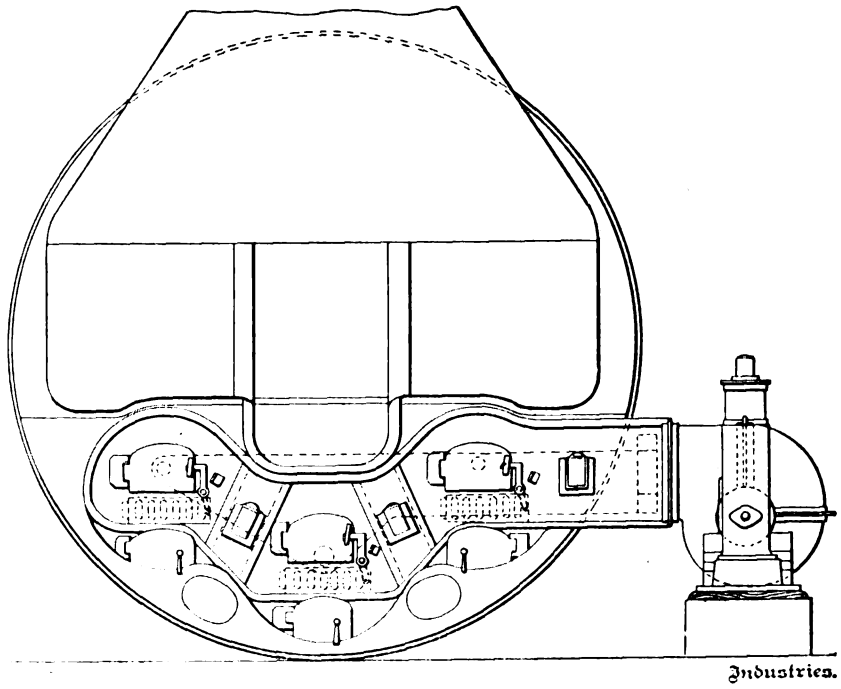

Fig. 2.

back from the position he held in 1887, when he believed in reducing the factor of safety to three—at least he probably concurred with Mr. Milton's paper advocating that step. The French Admiralty have adopted the same policy as the author had done.

The next paper read was by Mr. A. F. Yarrow, on

The Possible Advantage of using Highly Volatile Liquids in Lieu of Water for the Purposes of Propulsion.

The author had recently completed a steam launch 36ft. in length by 6ft. beam, and fitted her with an engine working with a highly volatile hydrocarbon. The weight of the hull is 14cwt., and that of the machinery 6cwt., making a total of only 1 ton. The engine is of the ordinary direct acting inverted type, provided with the usual link motion, feed pumps, &c., and the working fluid is a highly volatile hydrocarbon having a specific gravity of ·725 to ·730. This is evaporated in a generator consisting of a copper coil which is enclosed in a double sheet iron casing, the intermediate space between the casings being filled with asbestos. Below the coil is a ring-shaped Bunsen burner, through which a mixture of hydrocarbon and air is forced and ignited on issuing through the holes. In the bow of the boat is a 40-gallon air tight copper tank containing the hydrocarbon, and care is taken to make the bulkhead aft of it perfectly tight, so as to prevent the danger of the liquid finding its way into the central portions of the boat. This tank is placed in communication with the feed pumps by means of a pipe passing outside the boat close to the keel, and the feed pumps deliver into the bottom of the generator coil, whilst the exhaust from the engine passes by means of two condensing pipes also placed outside the boat and on either side of the keel into the top of the tank in the bow. These pipes, therefore, form a surface condenser. In addition to the engine pumps there are two hand pumps, one having its suction in connection with the tank and its delivery joining the delivery pipe from the engine pump; the other forcing air into the top of the tank, which becomes charged with vapour, and is passed by a separate small pipe to a supplementary Bunsen burner placed below the main burner. To start the launch the air pump is first worked by hand, and as soon as air charged with vapour finds its way to the supplementary burner it is ignited by means of a taper and heats the copper coil. After working the air pump for some minutes a few strokes are given with the hand feed pump, so as to send the hydrocarbon into the copper coil, which has meanwhile been heated up. The pressure immediately rises, and a communication is made by opening a valve between the upper part of the coil and the main burner, allowing a small quantity of the vapour to pass into the burner together with a suitable amount of air which is drawn in with it, and the mixture is ignited from the flame of the supplementary burner. When the main burner is fairly started the hand air pump and the hand feed pump may be stopped, and the engine can now be started, the main feed pumps keeping up the circulation of the hydrocarbon through the coil. From this moment the action is automatic, and neither engine nor generator require any further attention. The working pressure in the launch described can easily be maintained at 70lb. per square inch. After the feed has left the engine it passes through the exhaust pipes, is condensed and forced by the engine back into the tank, where it arrives in its original fluid form. The boat can run at a speed of from seven to eight miles per hour for several hours, with no other attention than that required to lubricate the bearings. The advantages claimed for this system are that the average time from lighting up until the launch is started at full speed does not exceed five minutes; that the entire central portion of the boat is available for passenger accommodation, which is about twice that of a steam launch of equal size; that there is a large saving in weight, owing to the small size of the vapour generator; that the fuel supply requires no attention; and that the whole arrangement is extremely clean. One person can take entire charge both of the steering and management of the machinery, and to stop the boat all that is required is to cut off the supply of vapour. The author has given the name of "Zephyr" to this type of launch. As regards the first cost, it is about equal to that of a steam propelled launch, and the cost for fuel may be calculated from the fact that, with a speed of from seven to eight miles an hour, the consumption of hydrocarbon is about 1¼ gallons per hour.

The discussion which followed was somewhat meagre, considering the great scientific, and possibly also great practical importance of this new type of vapour engine, not only for launches, but also for stationary purposes where small gas engines are now employed. Professor Lambert referred to some experiments in which he took part when a model of a steam engine was worked with steam and with hydrocarbon vapour. The fact that the specific heat of hydrocarbon is very much lower than that of water, and that the temperature corresponding to equal pressures is also lower, necessitates the employment of larger cylinder volumes as compared with steam engines working at the same pressure. The most important contribution during the discussion was made by Mr. White, of the Admiralty, who suggested that propelling machinery of this type might be adapted to lifeboats, where mechanical propulsion of one sort or another is very desirable, so as to leave the men fresh by the time they arrive at the wreck.

Two more papers were set down on the programme for the morning meeting; one by Mons. J. A. Normand, "On the Fineness of Vessels in Relation to Size and Speed," and the other by Mr. A. Blechynden, "On a Method of Approximately Determining the Mean Girth of a Ship;" but as neither author was present, and as the long discussion on Mr. Sennett's paper seemed to have exhausted the energy of the meeting, these two papers were taken as read.

The first paper read at the evening meeting on the 22nd March was by Mr. J. R. Fothergill, on

Forced Draught.

The system of supplying boilers with air above atmospheric pressure has long been known, having been introduced by John Ericcson in 1830 on the steamer "Corsair," trading between Liverpool and Belfast; but it is only during the past few years that it has met with commercial success, and some ship owners are even now reluctant to adopt it. The author prefers the closed ash pit to the closed stoke hold system. The quantity of air at 62°F. required for the combustion of 1lb. of coal is 140·6 cub. ft., or 10·7lb.; but in an ordinary multitubular furnace under natural draught, from 20lb. to 24lb. must be supplied to insure perfect combustion. With a funnel temperature of 600° this excess carries away about 20 per cent. of the heat units generated, and if the supply of air be restricted, only carbonic oxide is formed, giving 4400 units of heat per pound of carbon, instead of 14,500 units when carbonic acid is formed. These defects cannot be remedied under natural draught. A successful forced draught system must not be too expensive, must stand rough usage, suit present stoking arrangements, and admit of the use of natural draught should the machinery break down. The author's system is as follows: Across the boiler front (see Figs. 1 and 2) is a casing made of separate parts, and into this the air is forced by the fan, entering the ash pits through gridiron valves, shown dotted in Fig. 2. These valves are actuated by the movement of the furnace door latch. Another casing extends across the back of the boiler, and is connected with the front casing by a pipe running along the boiler side. The air supply is regulated by an air scoop in the front of the tube. Connected with the back casing are air pipes running through the boiler and opening by jets into the combustion chambers. At the end of the grate is the usual brick bridge, and behind is a gas deflector. The air leaves the fan at a water gauge pressure of 3in. to 3½in., and at the ash pits the pressure is from ·5in. to ·7in. Air is admitted through a perforated plate under the bridge to the combustion chamber. In all cases the air is admitted in small streams. As the gases leave the fire and pass over the bridge they are deflected, and the air from the back casing, rushing at great velocity through the perforated plate in very small streams, acts, as it were, like so many air pokers, stirring up the gases, commingling and uniting with them most effectively. The quantity of air so admitted can be supplemented from the ash pit through the air box under the bridge. The author did not think that the advantages derived from heating the air were worth the trouble and expense. The fan and driving engine that had been found most convenient were Chandler's combination of high speed engine and fan; that on the "Hypatia" had run for twenty-four days without stopping, passing 8000 cub. ft. to 10,000 cub. ft. of air per minute. Turning to the commercial advantages of the system, tables were quoted

Makers of engines: * Palmer's Company, Jarrow. † R. Napier & Sons, Glasgow. ‡ Earle's Company, Hull.

of steamers from 1250 tons to 3600 tons, with boilers working at from 65lb. to 160lb. steam pressure. These steamers are in the Indian, Mediterranean, and South of Spain trades. In the case of the s.s. "Marmora," which was fitted with the author's forced draught arrangement in 1884, a saving of £367 in the coal bill per annum resulted from the possibility of using inferior coal. In the s.s. "Dania" the introduction of forced draught reduced the coal consumption in the main boilers by 20 per cent. without material alteration of speed, whilst in the s.s. "Etna" an increase in speed of ·8 knots per hour (from 7·58 with natural to 8·38 with forced draught) was accompanied by a saving of 4·3 per cent. in the quantity of coal consumed for all purposes. In the case of the "Hypatia," which has just concluded her third Indian voyage, there is a slight increase of speed, and a saving of 13 per cent. in the consumption. The author concluded by calling attention to the fact that the "Marmora" sailed from the Tees on the 3rd October, 1884, whereas the "New York City" did not sail till the 13th of the same month, so the claim made that the latter was the first steamer ever worked at sea with forced draught cannot be sustained.

The next paper was by Mr. T. Soper, R.N., on

Boilers under Forced Draught on the Closed Stoke Hold System.

The author pointed out that this system had first been brought to the notice of members of the Institution in a paper by Mr. Butler in 1883, in which the results on the "Satellite" and "Conqueror" were given. It was then feared that the durability of boilers would be diminished; but now that the trial has lasted several years, it has been found that boilers are as good under forced draught as under the old system. The "Polyphemus" had her eight boilers fitted in 1884. The stoke holds are closed and air is supplied by four fans, and though the ship has since been engaged on very trying service, the boilers are still in a most satisfactory state, and capable of working with the original pressure of 110lb. Double distillers were fitted in 1887, as the deposition of scale during distillation led to the tubes leaking. In regard to torpedo boats, they are fitted with closed stoke holds, and when steaming down channel last May only two boilers gave trouble, and these not in any way owing to forced draught. Up to the present fifty vessels, representing a total i.h.p. of 254,000, had been fitted with this system, and the only cases in which difficulty was experienced were in three vessels of the "Archer" class, in which the boiler tubes leaked owing to local causes unconnected with forced draught. Recently, the "Porpoise," one of this class, had made a continuous run of ninety-six hours, at full power, with most satisfactory results. One advantage of the closed stoke hold in the navy is that the openings to the engine and boiler rooms can be reduced in size. Thus in the cruisers "Amphion" and "Orlando" the area of the air opening in the former is 207 sq. ft. for 5600 i.h.p., while in the latter it is only 103 sq. ft. for 8700 i.h.p. As the "Rattlesnake" is the only vessel in the navy worked continuously with more than one locomotive boiler, the results obtained with her are of interest. She has four boilers having a diameter of 5ft. 10in., and a length of 16ft. 6in., and a total grate area of 126 sq. ft., with a tube surface of 4085 sq. ft. The mean i.h.p. recorded on a three hours trial was 2740 i.h.p., and the speed of the vessel 19·5 knots, the engines working at a pressure of 135lb. and a mean air pressure of 2·39in. in the boiler rooms. The ship has been since engaged on most trying work, and the boilers work admirably. The only trouble was the burning of fire bars; but this has been completely remedied by the introduction of water pans in the ash pits, as usual with torpedo boat boilers. As the trials for maximum power under forced draught last for four hours, no reliable results have been obtained as to the consumption of coal. Mr. Soper then called attention to six of the belted cruisers, which are the largest vessels in the navy, and which up to the present have been tried with triple expansion engines, and six of these have within the past year completed their official trials. These six vessels were engined by three firms—Messrs. Napier, Palmer's Company, and Earle's Company. The engines are horizontal, and excepting details of construction, are practically the same in the different vessels. There are four double-ended boilers to each vessel, and each boiler is fitted with six furnaces, three at each end; in the "Orlando" and "Undaunted," by Palmer's Company, and the "Narcissus" and "Immortalité," by Earle's Company, there is one combustion chamber to each opposite pair of furnaces—that is, three combustion chambers, with waterways running fore and aft the boilers between them. In the "Australia" and "Galatea," by Messrs. Napier, there is one combustion chamber only to the six furnaces. The results obtained by the single combustion chamber boiler are superior to the others, as will be seen from the above table.

The discussion on these two papers was taken together.

Mr. James Howden differed from Mr. Fothergill, as he attached more value to the heating of the air supply. He denied that the cases described in the paper were really those of forced draughts. Thus the "Stella" has 3498 sq. ft. of heating area of boiler to an i.h.p. of 853, and the "Marmora" has 1700 sq. ft. with 396 i.h.p., both of which the speaker characterised as extravagant heating areas for natural draughts. His idea of the real meaning of forced draught was that it enables us to reduce boiler surface and increase horse power. In regard to the question of priority, he said that though the "Marmora" had gone to sea on the 3rd of October, 1884, and the "City of New York" not till the 13th of the same month, yet Mr. Fothergill had not applied this method to the old boilers of the "Marmora" till months after the speaker's paper before the Institution, and the "City of New York" had actually made a trial run in September of the same year. He pointed out that the illustrations accompanying Mr. Fothergill's paper were almost identical with those published by the speaker in 1884. In regard to Mr. Soper's paper, he objected that the trials were not so conclusive as a continuous run across the Atlantic.

Mr. Frank Marshall regarded the data of the working of merchant vessels given by Mr. Fothergill as of great value. He also pointed out the great collateral advantages of forced draught, such as cleanliness, lower temperature in the stoke hold, and that the speed is maintained while the furnaces are being cleared. As to the question of priority, it should be remembered that the method had been used by George Stephenson, and by Messrs. Thorneycroft and Yarrow, years ago. He claimed to have first applied it to large war vessels, viz., three large cruisers built for the Chinese Government in 1879, and he used the open stoke hold system, thus differing from both Messrs. Howden and Fothergill. He would substitute fire brick for the deflector, because if made of iron it could not escape being burnt away; and he would lengthen the fire bars more than Mr. Fothergill had done, so that more air could be taken through the fuel. Boilers used on this system both in the Italian and Russian navies had worked well. He also advocated a large combustion chamber, and illustrated his point by reference to the boilers of two Guion Line vessels that he had built eighteen years ago, and which he had recently been assured were as good now as they had ever been. Their dimensions were 15ft. 6in. diam. by 19ft. long, of 1¼in. plate. There were six furnaces and one large combustion chamber. Mr. A. Holt had adopted the same system. The Flora Rubbattino Company, of Italy, had thirty vessels worked on the Ferando system of forced draught, which only in unimportant details differs from Mr. Fothergill's. The ships work almost continuously, and their speed from Naples to Malta has increased from 11 or 11½ knots to 13 or 14 knots.

Mr. Linington called attention to the fact that fans were used to drive air into the furnace in a ship built thirty to thirty-five years ago. The advantage of closed ash pit over closed stoke hold depends on the number of boilers; and if there is but one the closed stoke hold system is simplicity itself.

Mr. Parker rose to state what had been done on this subject in the mercantile marine. Up to the present sixteen vessels had been fitted, mostly on Mr. Howden's system. In five cases it had been taken out for unexplained reasons, but in the remainder it was doing well. It is important to remember that these five vessels were fitted by contract, and as they were not such a success as the owner had anticipated, the forced draught apparatus was removed. The White Star Line had spent from £5,000 to £6,000 on experiments on the "Celtic," with the result that she now does better with eight boilers than previously with ten, representing an increase of 260 tons of cargo capacity.

Mr. Kirk pointed out that there is a great difference between the practice in the navy and mercantile marine. In the former it is required at an emergency to get the very utmost out of the machinery, and therefore much higher rates of combustion are required. Thus the Admiralty adopt a 2in. pressure, whereas in the merchant service only one of ½in. is used. He regarded the combustion chamber of the "Galatea" as excellent, because it allowed a better mixture of the gases.

Mr. Sennett defined forced draught to include only cases in which the air is forced down by fans. He pointed out that in the navy much greater horse power is required out of the same material than in the mercantile marine; thus, to take the case of the "Etna," the navy would require 1200 horse power, whereas it really only has 485. He remarked that the only objections to the system came from those who had had no practical experience of it.

Mr. Scott said that in addition to the sixteen vessels with forced draught noticed by Mr. Parker, there were six more under the management of Mr. Holt. The system was explained as of especial value, because securing regularity in Indian waters when during the monsoon season the vessel is travelling at the same rate as the wind.

Admiral de Horsey had used an iron deflector, and though it went into the ash pit once a month, it was so useful in saving the tubes that it was worth renewal. He remarked that the funnel damper had a great influence in dealing with forced draught.

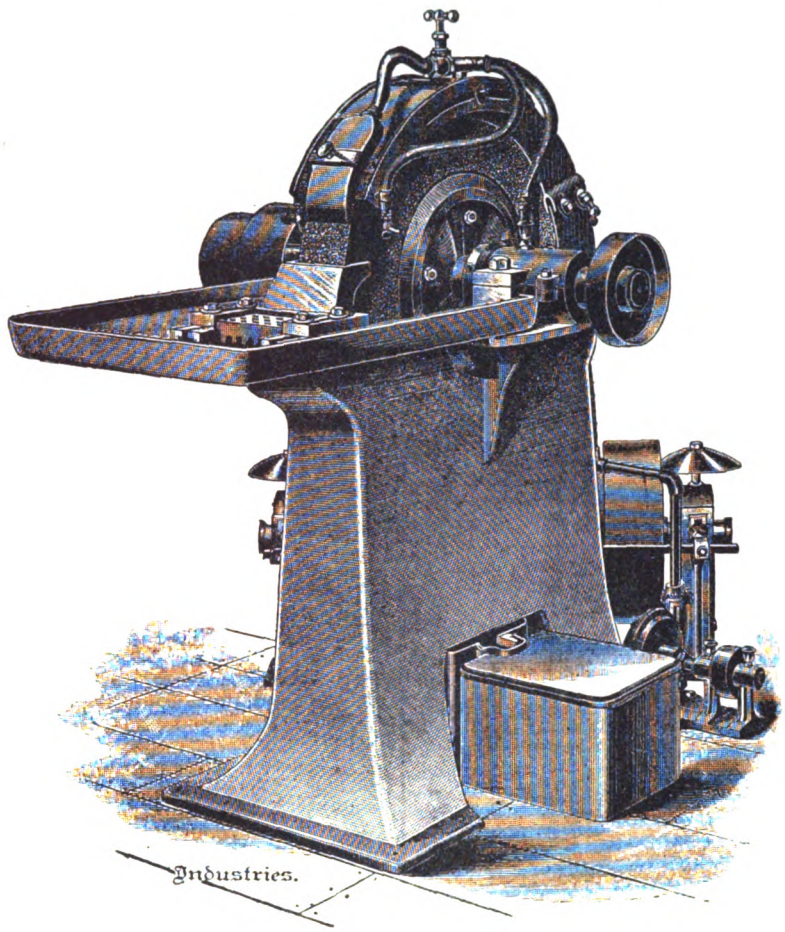
Mr. Bevis explained that the Holyhead boats had been fitted with a closed stoke hold with excellent results.

Mr. Fotheringill, in reply, objected that Mr. Howden had not caught his meaning. He did not think that heating the air was worth the cost, and Mr. Spence pointed out in his paper at Newcastle that the only gain he obtained was 4 per cent. In reference to the heating area of the boiler, he explained that those described were of the ordinary mercantile marine class with the ordinary heating surface, and the object of his paper was to show that boilers not designed for forced draught could be easily adapted, and would pay the cost of alteration in twelve months' running. As the air in these ships is mechanically driven, he thought it ought to be called forced draught. Mr. Marshall's fear that the baffles would not stand was needless, because they had stood. They had tried fire brick, asbestos, &c., for the deflector; but these materials had all failed, owing to accumulation of clinkers. They used iron plates, which burnt away every six weeks, but were readily renewed. In regard to the admission of the air at the bridge, as alluded to by Mr. Marshall, the system had been tried and failed. Mr. Sennett had overlooked the difference between forced draught and a high chimney, viz., that in the former the velocity of the gases can be kept down to a minimum. The quantity of air admitted is in round figures 18lb. of air per pound of coal, but the exact proportions cannot be easily ascertained.

(To be continued.)

SOME RECENT OFFICIAL REPORTS ON BOILER EXPLOSIONS.

Report No. 249 refers to an explosion which occurred shortly after three p.m. on the 29th November, 1887, to the larger cylinder of a "Slasher" sizing machine at the Washford Towel Mills, Buglawton, near Macclesfield. The explosion, fortunately, did not cause any serious injury to any person. The machine had been purchased second hand, by Mr. W. Hoyle, Primrose Vale Mills, and sold by him to Mr. Robert Calvert during last year. A new safety valve had been fixed and one longitudinal stay replaced since it came into Mr. Calvert's possession. This machine was fitted with two cylinders for the purpose of drying cotton yarn after being passed through size. One cylinder was 40in. diam., and the other, which exploded, 60in. diam., both being about 4ft. 11in. in length. The shell of the larger cylinder was made of five tinned sheet iron plates, from ·036in. to ·04in. in thickness at the fracture, and arranged longitudinally, with lap soldered, double riveted seams; rivets about 1¼in. diam. and 1in. pitch. Three hoops of T iron, 1in. by 1in. by ⅛in., placed about equal distances apart, secured by straps of hoop iron, soldered to the cylinder at each longitudinal seam, were fitted to the cylinder to resist collapse. The ends were $\frac{5}{16}$in. thick, flanged outwards 1¾in., and supported by nine longitudinal stays, ⅞in. diam., collared and riveted. Trunnions, 5¼in. in length, and 2⅜in. diam., with flanges 20in. diam., were secured at each end by thirty-eight ½in. bolts, and upon



Digitized by Google

these trunnions the cylinder revolved. The hole through each trunnion was $\frac{3}{4}\frac{1}{2}$in. diam., one being somewhat diminished in area by a tin tube for the purpose of removing the water formed by condensation. The machine was fitted with a pressure gauge graduated to 200lb., one safety valve $\frac{3}{4}\frac{3}{2}$in. diam., loaded by a dead weight to 14lb., and a small extra horseshoe shaped weight of $\frac{1}{4}$lb.; one vacuum valve at each end of each cylinder, $1\frac{3}{4}$in. diam., held in position by spiral springs; one water trap, with a ball escape valve, having a vacuum valve in its cover. The cylinders were supplied with steam from a Cornish boiler working at 50lb. per square inch, about twenty-five yards distant, through wrought iron pipes 1in. diam. There was no reducing valve, steam admission being regulated by a cock. Owing to Mr. Calvert having failed to give notice of the explosion to the Board of Trade authorities, as required by the Boiler Explosions Act, 1882, the inspector did not examine the cylinder until about ten days after the accident, and the machine had then been removed to Accrington, and taken to pieces for repair. It appeared that the cylindrical portion of the larger cylinder ruptured throughout its whole length, the fracture running about $4\frac{1}{2}$in. to 12in. from one of the longitudinal seams, then extending round each end. From the evidence it appeared that the safety valve did not commence to blow off until the pressure gauge indicated about 18lb., or about 4lb. more than the calculated load per square inch upon the valve. From tests made of the tensile strength per square inch of the tinned sheet iron plates, it was shown that of ten strips from the circumferential direction of the cylinder the mean breaking load was 46,141lb., which, taking the pressure at 20lb. per square inch, shows the cylinder to have been working with a factor of safety of 2·75. Taking the lowest test of tensile strength obtained, viz., 40,780lb., the factor would only be 2·45, even assuming the joints or seams to be as strong as the solid sheet. The inspector concludes that the explosion was due to the cylinder having been worked at a higher pressure than it was fit for; and observes, "it is fortunate for the owner that the explosion was unattended by serious consequences, as he appears to have taken no steps to satisfy himself as to the fitness of the cylinder for what he regarded as its working pressure." The Engineer Surveyor-in-Chief, Mr. Traill, while confirming the opinion of the inspector, adds: "This is another illustration which shows how little some men apparently think of the importance of taking reasonable steps to satisfy themselves that a vessel is capable of withstanding the pressure to which they subject it, from time to time." The owner in his evidence expressed a conviction that the safety valve was inoperative, and allowed the cylinder to receive the full boiler pressure (at the time 40lb.); but the inspector's report does not confirm this view, and there is little doubt that this explosion is entirely due to the improper manner in which the maker of the "Slasher" arranged for steam admission and escape. The inlet pipe was 1in. diam., and the safety valve being only $\frac{3}{4}\frac{3}{2}$in. diam., was unable to discharge more than a fraction of the steam supplied from the boiler; therefore as at any time there might accidentally be a stoppage of the passage of wet yarn over the cylinders, the supply of steam would exceed the condensation, and allow the pressure to increase. From the inspector's calculation the boiler pressure would just about equal the bursting pressure of the larger cylinder; and in the event of a stoppage of the machine there does not appear to be much doubt that pressure might rise to the full boiler pressure. The remedy in all such cases is obvious: the area of the inlet pipe should be properly proportioned to the area of the safety valve, so that the discharging capacity and power of the safety valve shall at least equal the steam supplying power of the inlet pipe.

On the 27th November, 1887, about 11 a.m., the boiler of a small steam coaster blew up, and fell into the sea, off Burntisland, in the Firth of Forth, severely scalding, but not fatally, the master and engineman. The vessel, which belonged to Mr. John Lindsay, High St. Anthony's Boat-building Yard, Newcastle-on-Tyne, was much injured, but was afterwards towed into Leith. From such particulars as could be obtained, the boiler not being forthcoming, it having sunk in from 5 to 21 fathoms of water, it appears to have been an ordinary vertical cylindrical with a fire box provided with two cross tubes. The shell was 11ft. high and 5ft. diam., fire box about 4ft. diam., and of the unusual height of 8ft., leaving only 2ft. 9in. for steam and water space. The uptake was 18in. diam., lined with fire brick; there were also four stays $1\frac{1}{8}$in. diam. between the fire box top and crown of the shell. It was made by Mr. Wm. Horsley, White Hill Point, North Shields, in 1876. The boiler had been proposed for insurance to an insurance company, but found in bad condition. The insurance was then deferred by the company on the 12th April, 1887, until the boiler was properly repaired both in the fire box and the shell, and for Mr. Lindsay to enter into an undertaking to feed only with fresh water instead of using salt water, as had previously been the custom. Although reminded, and so recently as the 24th of last October, of the importance of immediate attendance to these suggestions, the owner appears to have continued to work the boiler in its known bad condition, and with salt water, until it finally exploded. The engineman stated that the load on the safety valve was not constant, as he "used to shift the weight along the lever according to what he considered requisite." He admitted using a pressure of 60lb., but as the load with the weights at the end of the levers would be 70lb. per square inch, it is possible the pressure may occasionally have reached that amount. One statement of the engineman seems worthy of record: "I used to guess," he said, "at the saltness, and sometimes I tried a potato in the water. I never saw a potato float." There is little doubt that the explosion was due to the defective condition of the fire box, which was worn out. These particulars are taken from Report No 250.

Report No. 251 does not deal with the explosion either of a steam boiler, generator, or vessel intended for the use of steam under pressure, but with the explosion of a vessel used only for the purpose of heating water to the boiling point, for the purpose of cask washing, at the brewery of Messrs. Greatorex Brothers, Brooks' Bar, Manchester. The explosion occurred on the 29th of December, 1887, about 3 p.m., and resulted in the death of one man, who was a barrel washer. The water heater was a plain cylindrical vessel 4ft. 5in. diam., 19ft. 4in. in length, with flat ends, made throughout of $\frac{3}{8}$in. plates, single riveted, except the upper part of the front end, which was $\frac{7}{16}$in. thick. The ends were secured by light angle iron $2\frac{1}{2}$in. by $2\frac{1}{2}$in. by $\frac{3}{8}$in., the back end being in one piece, and the front end (which gave way) in two. A longitudinal stay, $1\frac{1}{2}$in. square, was fitted in the centre, and secured by pins 1in. diam. to short pieces of angle iron 3in. by 3in. by $\frac{5}{8}$in., riveted on. The heater was provided with a glass water gauge; one alarm, or very small safety valve, only $\frac{1}{4}$in. diam., loaded to 2lb. per square inch, and provided with an escape pipe $\frac{1}{4}$in. diam., 8ft. in length; a filling and an emptying pipe; a cock for drawing off hot water, and a pipe to admit steam for heating the water. The heater was twenty-eight years old, having been made by Messrs. Gadd & Hill, engineers, Salford, in 1860. The stay pin of the front end appears to have given way, and the end being flawed at the root nearly all the way round, then gave way—blowing out, but with no great force, as the heater was only pushed backwards about 3ft. 6in. The boiler from which the steam was supplied usually worked at about 50lb., with the safety valves loaded to 60lb. per square inch. As no means whatever, beyond the very small safety valve—which it was admitted was only intended to show when steam was forming—was provided, pressure could and did rise in the heater, as was shown in the evidence by the fact that the feed water had on several previous occasions been forced back into a tank 36ft. above the heater. Although this explosion does not refer either to a steam boiler, generator, or vessel intended to work under pressure, yet the lesson it conveys is an extremely valuable one, and the facts should not be overlooked by persons who may be using steam for similar or other purposes. It would be well if all who have apparatus of a like nature were to have them examined and take advice as to their safety or otherwise. Accidents could be cheaply avoided. In this case absolute safety might have been secured by fixing to the water heater an open stand pipe of sufficient diameter.

IMPROVED TOOL GRINDING MACHINE.

IMPROVED TOOL GRINDING MACHINE.

We are indebted to our contemporary the *American Manufacturer* for the accompanying illustration showing an improved tool grinding machine, constructed by the Springfield Glue and Emery Wheel Company, Springfield, Mass. The novel feature in this machine is the use of a specially designed "water proof" emery wheel, instead of the stones usually employed. It is claimed for this emery wheel that it employs less space, makes less dirt, and does not wear so quickly into ruts or grooves as the grindstone does, besides doing the work much quicker. The grade of coarseness of the grit and the degree of hardness of the emery wheel may be varied to suit the work under operation. The emery wheel is surrounded by a hood, except at the place where the tool is ground; and this arrangement prevents the water from splashing. The hood is adjustable to compensate for the wear of the emery wheel. The water is introduced by a tube into a brass chamber shown in our illustration, from where it is evenly distributed over the whole face of the grinding wheel, and the sides of it are supplied with water by means of small india-rubber tubes. The waste water from the wheel falls into an iron tank, where the particles of steel and emery settle. From this tank the overflow, which is comparatively free from suspended matter, is conducted to a second tank, from which it is again conveyed to the grinding wheel by means of a centrifugal pump, the supply being regulated by a valve. As the first tank has no pipe connections it may be easily removed and cleaned.

FOREIGN INDUSTRIES.

(From our own Correspondents.)

PARIS, 3rd April, 1888.

The Iron Market.—The iron market here is still kept in a wavering and uncertain state by the timid attitude of the merchants. Nominally quotations are unaltered, but many dealings take place below official prices. The weather still delays building operations, and the resignation of the Government has introduced another element of uncertainty into the situation. These influences are, however, scarcely appreciable in the provinces, where there is a moderately good demand for most classes of iron goods. The representatives of the Nord and the Centre meet again this week to settle the boundaries of their respective districts. When the two syndicates have come to an agreement on this point we may expect an advance in prices, and probably the advance will lead to increased activity. The most remarkable feature of the present time is the steady rise which is taking place in the price of heavy castings. Pipes also are considerably higher. The rumour which credited a French firm as having obtained a large order for pipes for the transport of petroleum from the wells at Baku to Batoum, has been officially denied. The pipes required for that purpose are, it is now said, to be of wrought iron or steel. On the whole the outlook is cheering.

Discovery of Iron Ore in Algeria.—Discoveries of iron ore deposits have been made in Algeria, in the province of Oran, which are reported by the experts sent to investigate the matter to be of great value, rivalling the famous deposits of Mokta-el-Hadid. The ore averages 65 per cent. of iron. The deposits, which are of large extent, are situated within seven miles of the railway station of Bou-Tlelis, at the mouth of the Madagre river, where there is a good harbour and facilities for shipping the ore. This discovery is likely to be of immense importance to the French iron industry.

The Metal Market.—The action of the syndicate, coupled with the necessity which is forcing consumers into the market, keeps up the price of copper; but stocks are steadily increasing, both in France and in England. Consumers buy only sufficient for the needs of the moment, and these are becoming less week by week, in consequence of the restriction of trade by the prevailing high prices. Chili bars are quoted at £80. There is but little doing in tin; consumption is steadily diminishing, and it is becoming clear that the syndicate cannot much longer keep up the price. Banca is quoted £176. Lead is quiet at £15. Spelter is weak, Silesian being quoted at £20. 18s.

Foreign Workmen.—In a report of the commission appointed to examine the question of foreign workmen in France, it is stated that in the Department of the Nord, out of a total population of 1,670,184, there are 305,524 foreigners, chiefly Belgians, a proportion of 182 per 1000. In the Pas-de-Calais and the Oise the proportion is 30 per 1000. The Germans predominate in the north-east. In the Meurthe-et-Moselle, out of 431,693 persons, 32,884 are of foreign origin, or 76 per 1000. At Belfort the foreign element amounts to 104 per 1000; in the Department of the Seine to 70 per 1000.

BERLIN, 2nd April, 1888.

The Coal Market.—Since my last report the market as regards coal for domestic purposes has become somewhat weaker, but there still remains a large number of orders to be filled. In consequence of the recent snow drifts, considerable difficulty has been experienced in the transport of coal; and the scarcity of waggons has again made itself evident. The active business which was done during the first half of March has only benefited the dealers, but not the colliery owners, since at the beginning of that month the cheap summer prices were already ruling, whilst the consumers had to pay the higher winter prices, owing to the difficulties of transport.

Railway Tariff on Cotton Goods.—Cotton and cotton goods imported into Russia from England and America are either sent by sea direct or landed in a German port and then forwarded by rail. Of late the traffic in cotton over the German railways has shown a tendency to decrease, and with a view to prevent the entire loss of this business the German railway administrators have, partly on the initiative of the Bremen Cotton Exchange, reduced their freight charges on cotton and cotton goods sent to the Polish frontier from German ports in consignments of not less than 10 tons. By this means German railway companies hope to retain at least a portion of the traffic in cotton going to Russia.

The Iron Market.—Indications are not wanting that sooner or later struggles and difficulties will arise between the various syndicates and outsiders who have steadily refused to join them. It is owing to the action of the rolled iron syndicate that within a few months the price of bar iron has risen from 110s. to 125s., whilst the prices of other kinds of finished iron have proportionately increased. If the international iron market remains firm, the syndicates will probably retain their leading position. The method at present adopted by them in their struggle against outsiders is to make special concessions to large dealers, provided the latter will agree not to deal with non-syndicated works; but should dealers disregard the wishes of the syndicate, the latter would either treat them as ordinary customers, or even go so far as to refuse to supply them on any terms. Blast furnaces are well employed, and orders for forge pig are plentiful at 50s., with an upward tendency. Some brands of foundry pig have risen even to 59s. The home trade in all branches is fairly brisk, but the export trade is languishing, which is partly due to the depreciation of Russian paper money. The Westphalian rolled iron syndicate have booked up to the 18th of March, orders for over 57,000 tons of finished iron, including some small orders standing over from last year. The orders booked during March are likely to exceed 7000 tons.

The Spirit Industry.—Our exports of spirits to Spain, *vid* Hamburg, have never been so insignificant as at the present time. This decrease in the export trade to Spain is due to the small exports of Spanish wines, to the unfavourable condition of the Spanish Customs tariffs as regards German imports, and to the great competition of the Carlsham spirit manufactory in Sweden. Large cargoes of Swedish spirits are constantly being shipped to Spain, the result being that most of the ports in that country are flooded with the Swedish article, which is sold at a very low price. The competition of Sweden has not only reduced our exports to Spain, but is also the cause of the present low prices obtainable for spirits in the home market.

Underground Cables.—Some time ago a committee was appointed in this town to carry out a comprehensive series of experiments with underground cables as used for electric lighting purposes. The experiments were made partly with sections of cables used in the various central station supply systems, and partly with cables specially laid for the purpose in the works of Messrs. Siemens and Halske. The experiments are now nearly completed, and the results will be communicated at an early date in the form of a paper on underground conductors to the Berlin Society of Electricians.

VIENNA, 2nd April, 1888.

The Iron Market.—A slight improvement has taken place during the past week in merchant bars and building iron, but on the whole the market remains without animation. Hungarian iron masters are beginning to consider the spring season as practically lost; and even the good condition of the crops does not seem to infuse any animation into the engine trades. In the northern parts of the empire iron founders are endeavouring to arrange for a more uniform scale of prices. For rough castings, such as fire bars and stove plates, the base price will probably be 80fl. per ton. It has been already reported that a small arms factory is in course of construction in Buda-Pesth. An additional proposal for the erection of a large engineering works and waggon factory has now been brought forward. There is also a proposal for the establishment of a gigantic beet sugar factory in Hungary; but the details have not yet been elaborated. The Hungarian State Railway works have secured an order for ten locomotives for the Oriental railways, which are to be delivered within the year.

Ballooning Exhibition.—An Exhibition of Balloons and Aëronautical Appliances was opened here yesterday. There are in all twelve inflated balloons of various shapes. Safety valves, steering apparatus, scientific instruments used in ballooning, and a few flying machines are also shown. There is no aëronautical department in our army, though possibly this Exhibition may draw attention to the importance of the subject.

Electric Lighting.—Some alterations are being made in the central station from which the Opera is supplied. When the steam dynamos were first erected, the vibration communicated through the walls to the adjoining buildings was so great that in some rooms it was impossible to write, and the owners of the property commenced legal proceedings, with the result that the Gas Association was ordered to discontinue the nuisance on a penalty of 5,000fl. for each infringement of this order. To overcome the difficulty, the company have laid down an enormous foundation block of concrete, on which the steam dynamos are placed. This block is completely detached from the walls of the building, so that no vibration of any kind will be communicated to the neighbouring houses. In Buda-Pesth there is now a fair number of large electric light installations. Amongst these I may mention the National Theatre with 2040 lamps, the Post and Telegraph Offices with 200 lamps, a number of large mills each with 300 to 400 lamps, the Academy with 29 arcs, the station, workshops, and round house of the State Railway with 70 arc and 700 glow lamps, and the engineering works of the same railway with 50 arc and 200 glow lamps. Most of these installations have been carried out by Messrs. Ganz and Co., of Buda-Pesth, and in that for the railway there are used three large steam dynamos supplying alternating currents. Messrs. Ganz & Co. are very busy with alternators and transformers, and will shortly supply some more machinery to the installation at Rome. This installation is the largest hitherto erected by the firm, and although you have already given a plan of the machinery as it will eventually be installed, the following particulars of the present condition of the station may be of interest: There are now erected four steam dynamos, two of 75 kilo.-watts (150 i.h.p.) each, and two of 320 kilo.-watts (600 i.h.p.) each. The small machines run at 250 revolutions per minute, have twenty poles, and are self exerting. The large machines are separately excited, have forty poles, and run at 125 revolutions per minute. The current is supplied at 1800 to 2000 volts, and the transformers have a reducing factor of 18 to 1 or 36 to 1, according as the lamps used are 100 or 50 volt lamps. The present capacity of the station is 1500 i.h.p.; but when the work now in hand is completed the capacity will be 2700 i.h.p. Steam is supplied by Babcock & Wilcox boilers, which are fired with coke. The current is conducted in three principal circuits supplying theatres, shops, and large establishments in various parts of the town. The total cost of the station when completed will amount to about £60,000.

BRUSSELS, 3rd April, 1888.

The Coal Market.—Delivery is now being rapidly made of the supplies of coal which mine owners have been forced to keep back on account of the stoppage of canal traffic and of the scarcity of rolling stock. The prospect of fresh contracts is producing greater animation in the market. Negotiations are in progress for the formation of a coke syndicate between the Westphalian and Belgian producers, the districts in which it will operate being to the east of France and the Grand Duchy of Luxembourg. The Germans are greatly in favour of this arrangement, as they will derive most benefit from it. The Société de Monceau-Fontaine et Martinet has obtained an order for 1500 to 2000 tons of coal required for the Copenhagen Exhibition, the order having been secured by M. Firmin Riehe, the manager of the colliery, who personally visited Denmark. The Mariemont and Bascoup collieries have already been in treaty for imports of coal into Denmark, but their prices were too high. The Monceau-Fontaine et Martinet Colliery intend to ship the coal to Denmark by sailing vessels which arrive at Ghent with timber from the Baltic. The same company hopes to do business with the Danish State railways in briquettes. The balance sheet of the Hornu et Wasmes Colliery, which has a capital of £144,000, shows a net profit for last year of £8,400. The Grand-Mambourg-Sablonnière Colliery, with a capital of £149,000, shows a profit of £8,464 on last year's working, of which £4,800 has been paid in dividends.

The Metal Market.—There have been some fluctuations in the metal market, but pig iron continues firm, though there are some complaints as to the quality. In spite of the new tariff which has come into force in Italy, orders are being constantly received from that country. The tariff has, however, had the effect of keeping out Belgian merchant bars and rolled iron of small sections, which are now being made by Italian works; but for large sections, and especially for girders, purchases are likely to be made from Belgium for a long time to come. This country has almost a monopoly in the export of girders, even England being unable to compete in this line. A good trade is being done in waggons and material for the same. In plates we are likely to be beaten by the Germans, as Krupp is now delivering 100 tons of plates to the Belgian State Railway Works at Malines. A private firm here has also placed an order for sheets in Germany. Several engineering works are very busy. Iron manufacturers have decided to press the Minister of Finance to allow, for a time at least, a drawback on forge pig obtained from abroad. Considering the high price of crude iron, this demand of the manufacturers of finished iron can hardly be called unreasonable, although it may somewhat prejudice the position of the blast furnaces. These, in their turn, would therefore ask for some concession in freights or in another direction. The Ougrée iron works have contracted to supply several hundred tons of steel plates for England.

The Glass Trade.—Prices are still weak, and the production exceeds the demand. The *fours-à-bassin* are certainly very economical in their working, but they have assisted in bringing about the present overproduction, it being now considered the proper thing for all works to have such furnaces. Among those who have erected or are erecting them are the Jumet and Gosselies works, and the firms of L. Mondron, L. Lambert, and Foucalt-Frison. Complaints are made that the convention is not being strictly adhered to.

Electric Traction at Brussels.—The annual report of the Administrative Council of the Tramway Company states that the working of three cars electrically during 1887 has resulted in a loss of £635. The service was commenced on the 17th of April, 1885, with one car running between the Place Royale and the Rue Belliard. A second car was run on the 8th May, and a third on the 19th September. These cars are at present running in the Rue de la Loi. The electric cars covered last year 34,500 miles. The financial failure, although not officially so stated, is due to the rapid wearing out of the accumulators. The depreciation of these is calculated at 22 centimes per kilometre—or say 3½d. per car mile; and as this estimate does not allow for general charges, nor for the cost of power, it is evident that the total working expenses must be considerable. The destruction of the plates is ascribed to the continual surging of the acid among them, coupled with the vibration to which the cells are exposed. M. Julien proposes to remedy the defect by placing a number of rubber rings round the plates, the rubbers to act as separators, and at the same time to sub-divide the acid into smaller quantities, and so limit the surging action.

DÜSSELDORF, 2nd April, 1888.

The Iron Market.—The calm which showed itself in certain branches of the iron trade a week ago has since spread over the whole. In some degree it is, no doubt, attributable to the season of Easter; but it is impossible to overlook the fact that the trade, oppressed by the

Digitized by Google

weight of high prices, is wanting in much of the life and vigour which distinguished it at the beginning of the year. Judged only from the published market reports, an outsider would be led to believe that the situation has in no way changed; but a very little intercourse with manufacturers is sufficient to convince the most sceptical that confidence has been weakened, and that an uneasy and anxious feeling prevails everywhere. The syndicate system is less enthusiastically talked about; indeed, it is easy to discern a lurking suspicion that this hobby has been ridden too fast and too far, and that the large profits which have been made in the course of the last eight months are in reality nothing better than a mortgage on the trade of the future. The market for pig iron is much less animated. The calm affects all classes, but is most marked in forge pig. The fact that the stocks in hand, small though they be, have been greater at the end of February than at the close of the preceding month, is regarded as significant of a changed order of things. The production of pig in February amounted to 338,841 tons, an average of 11,684 tons a day, against 346,962 tons, and a daily average of 11,192 tons in January last, and 270,726 tons in February of 1887. The markets for finished iron and steel are also dull. There is no life in the business in bars, and owing perhaps to the wintry weather, joists are not in good demand. The prices for bars are now £6. 5s. for the inner zone, and £6. 7s. 6d. for the outer. Hoops are less eagerly sought after, and sheets share in the general dulness. A fair amount of business is being done in common plates. The statistics of production issued by the plate syndicate of Western Germany show an output of 9220 tons in February, against 9224 tons in January. The deliveries in the same periods were 9409 tons and 8469 tons respectively. For the Portuguese railway contracts for 11,000 tons of steel rails, for which the Ebbw Vale Company tendered lowest with £4. 6s. 6d., and the Cockerill Company followed next with £4. 11s. 5d., the Bochum Verein tendered £4. 12s. 4d., Krupp £4. 13s. 7d., and the Gutheffnungshütte £5 a ton.

The Price of German Iron.—Now, when the question of the extinction of the export trade in German iron is being forced upon public attention, it will be interesting to give a few facts tending to show that the present high prices are not likely soon to be reduced. Since the year 1886, the market price of finished iron has risen nearly 40 per cent., while that of crude iron has advanced only about 30 per cent. The rates for finished iron leave only a moderate margin for profits; therefore if a reduction is to be effected, it must first be made in pig iron. But the cost of production has nearly kept pace with the advance in pig iron. Coke is 55 per cent. dearer now than it was in 1886, and ore has risen in price about 30 per cent. It appears certain from these facts that no downward movement is possible for some time to come.

Linen Yarns.—Though the trade in linen woven goods is somewhat languid, the spinning mills are kept in a state of activity. The report received this week from Bielefeld describes the yarn market as fairly animated, and prices as very firm.

Another Coffee "Ring."—Another ring has been formed at Frankfort, for the purpose of "cornering" coffee. The announcement of the establishment of this speculative syndicate has caused general indignation throughout the country, and the attention of the Government has been directed to this new attempt to fleece the working classes for the benefit of a ring of speculators.

LILLE, 3rd April, 1888.

Textile Manufactures.—The week immediately preceding Easter brought, as was expected, a great increase of business to the textile goods trade. The holidays will cause the present week to be a period of inactivity. This holiday effect will be intensified by the fresh evidence of instability afforded by the resignation of the Government. It is vain to hope for better trade so long as ministerial crises are of frequent occurrence. Apart from these influences, circumstances are favourable to a revival of business. For the manufacturers of linen goods the week has been a period of disappointment. The inclemency of the season has delayed the spring trade; retail buyers being unable to estimate the probable duration of the season. If the bad weather continues for another fortnight it is certain that all spring goods will be a drag in the market. This prospect has a very depressing effect in the woollen trade of the Roubaix district. Goods for women's wear are neglected, and prices are very low. Merinos sell at 5 centimes per metre less than in 1886, though wool, the raw material, is 20 per cent. dearer. During the last week business has revived a little at Roubaix, orders coming to hand pretty freely; but it is yet too early to discern whether this is more than a temporary spurt, and the current week must necessarily be a dull one for business. In another week it will be easier to estimate what the true tendencies of trade are.

Flax and Yarn Markets.—There is still a good course of business in home grown flax, Walloon and Douai produce being in brisk demand at firm prices. Russian produce has been less dealt in, and the market is unsteady. The business in yarns is animated. In the course of the past week large dealings have taken place both on home and on foreign account. Prices, however, remain unaltered. Jute goods are very active, and there are indications of continued life in this direction.

The Iron Market.—Business in iron is by no means active, and for the moment only small dealings take place. This comparative calm is, however, to be attributed to the fact that consumers have, in many instances, provided for their wants for some time to come. There is no question of lower rates, as manufacturers evince no disposition to tempt buyers with concessions in prices. The action of the Paris merchants in underselling the market tends to make manufacturers deal directly with consumers, a practice which is now well established in this district. So far from prices giving way, a further rise seems certain. In a few months pig iron has advanced from 34s. to 40s. a ton, and coal for metallurgical purposes, which three months ago could be bought for 6s. 8d. a ton, now sells at 8s. 9d.

AMSTERDAM, 3rd April, 1888.

The Drainage of the Zuyder Zee.—The Zuyder Zee Association proposes to seriously take this work in hand by building a mole between the islands of North Holland, or between Medemblik, in Holland, and Stavoren, in Friesland, and pumping out the sea water by powerful engines. The Association was formed to consider how the gigantic work could be best accomplished, and thus to pave the way for a public company to carry it out. The Association now appeals for subscriptions to a loan of 90,000 guilders, to be repaid when the company is formed. With the money so raised they propose to appoint a staff of engineers in order to execute a series of experiments in a thorough manner. Experts have no doubt that the Zuyder Zee can be drained; but many believe that the State alone is able to cope with the many engineering and financial difficulties which must be overcome before the task is completed. The drainage of Haarlem Lake in 1849-53 was considered a wonderful affair at the time, for the sea covered 45,000 acres, and an enormous quantity of water had to be pumped back into the ocean. This, however, was only a small affair compared with that of draining the Zuyder Zee.

Mail Steamers.—The Government Bill for carrying out a contract with a Dutch syndicate, which is to establish a subsidised mail service in the Dutch East Indies, to which I recently referred, has passed the First Chamber of the States-General, and now lies before the King for his sanction. The past year's working has proved sufficiently profitable to enable the Royal West Indian Steamship Company to announce a dividend of 3½ per cent. to the shareholders. There was a good increase in the general traffic, notably with the British Colonies and Venezuela. The boats of this company keep up a monthly steam service between Amsterdam and Surinam, calling at different ports on the way, and carrying the Royal mails, for which it receives a State subsidy. More capital has been raised lately, with the view to establish a new line of steamers between Dutch Guiana and New York, *viâ* Curaçao and Port-au-Prince, Hayti.

WINTERTHUR, 2nd April, 1888.

Tariff Changes.—The fiscal policy of Switzerland has hitherto been of a free trade nature, but a change is to be made owing to the clamour of some who desire protection for their own industries, though they do not want protection for general trade. The following are among the alterations in the duties which will come into force on the 1st of May: Articles made of wrought and malleable cast iron, steel, tinned sheets and wire—polished or tinned, 150fr. instead of 70fr. per ton; cotton yarns, three or more ply, dyed, in skeins, 350fr. instead of 110fr.; cotton yarns in small skeins, or on spools intended for the retail trade, 350fr. instead of 200fr.; cotton covers, embroidered, 500fr. instead of 300fr.; cotton hosiery 500fr. instead of 250fr.; boots and shoes, superior, 1500fr. instead of 800fr.; boots and shoes, coarse, 500fr. instead of 350fr.; basket work, of rough rushes, 40fr. instead of 20fr.; fine basket work 120fr. instead of 80fr.

Foreign Trade.—The imports during 1887 amounted in round figures to £26,000,000, and the exports to £24,000,000. Among the latter the items of manufactured cotton goods and silk, and machinery, are prominent, in spite of the fact that we have to obtain our raw material abroad, and that heavy protective duties exist in the surrounding countries. The following are the values last year:—

	Imports.	Exports.
Cotton goods	£1,131,693	£6,275,357
Silk goods	478,940	4,865,776
Machinery	313,226	743,693

Other important items of our foreign trade are the following:—

	Imports.	Exports.
Watches and clocks	£104,061	£3,227,128
Cheese	82,584	1,627,109
Condensed milk	24	432,276

In all other articles the balance is against us, especially in food stuffs. Thus the imports of flour amounted to £3,553,336, and the exports to £59,443.

MADRID, 2nd April, 1888.

Iron Ore Mines.—An English company has acquired the mines of Calasparra, in the province of Murcia, and will build a private railway to connect them with the general railway system. The ore from these mines will be among the best shipped from Spain; but owing to the fact that shipment will take place from the Mediterranean, the supplies are more likely to go to America than to Europe, so long as Bilbao maintains its present output.

Shipbuilding.—The contract for building three large cruisers for the Spanish Government, at a cost of about £2,000,000, is exciting much interest in industrial circles. The last day for the receipt of tenders was the 28th ult., and it is understood that nine proposals have been made, five coming from English firms with Spanish connections.

Electric Lighting.—The Municipality of Caceres, the capital of a province celebrated for its phosphate mines, invites tenders for the electric lighting of the town, which contains about 13,000 inhabitants.

Coal Mining.—No sooner had traffic been re-opened on the Asturian railways than a fresh snow storm of unexampled severity has completely blocked the lines. The coal mines in this part of the country are worked by adits opened on the side of the mountains, and the coal is brought down inclined planes to the valley. The fall of snow renders it impossible to use these, and there is great distress in the district in consequence.

NEW YORK, 24th March, 1888.

The Coal Market.—A dispute has arisen between the Lehigh and other companies about the inequality of production during the strike. As the allotment of percentages of tonnage expires on April 1st, and as the Lehigh companies are now delivering coal in New York at less than the regular rates, the trade will be disorganised unless an agreement is soon reached.

The Iron and Steel Market.—During the week there has been a much larger business in pig iron than for some time past. Several large sales of inferior grade irons have been made to pipe founders at extremely low figures, which will relieve the market for some time to come. The furnace owners who were forced to suspend work during the late strike have mostly blown out, and there has been considerable shrinkage in the production of charcoal iron. A decrease of 5½ per cent. in one month and 25½ per cent. since November last in the quantity of iron produced, implies important changes in many branches of manufacture. In the better qualities of iron the conditions of the market are unchanged, the supply being about equal to the demand, which is still light. Prices are $20·50 to $21 per ton for No. 1 foundry, $19 for No. 2, and $17 to $17·50 for grey forge. Special brands bring a little more money, but anything new or doubtful sells at from 50 cents to a dollar less per ton. Business in manufactured iron is very unsatisfactory. There is a fair amount of business done, but at low prices. It is not possible to determine how much business has been sent abroad, as buyers do not care to be prominently known as consumers of foreign metal; but the absence of a demand for certain kinds of iron is due to the fact that foreign iron has been sold here, duty paid, at $2 per ton less than our manufacturers have been able to quote. To reduce the cost is the only way to meet the situation, and this will have to be done sooner or later. Prices are nominally at 1·9 cents to 2 cents per lb. for best refined bars, 2·1 cents to 2·15 cents for plates, and 2·15 cents to 2·20 cents for angles, although most of the business has been done at $\frac{1}{10}$ cent lower than the lowest figure quoted. The steel rail market has been quiet. Within the last ten days orders have been placed for 18,000 tons in small lots at $31·50 to $32 per ton, but large contracts are not likely to be placed while the tariff agitation continues. The King Iron and Bridge Company have purchased nine acres of land in Cleveland, for the purpose of removing their present works and increasing their facilities. Building has already commenced. The new works will have three times the capacity of the old, and the plant will cost about £200,000.

Puddling Furnaces.—The North Chicago Rolling Mill Company, at their Milwaukee works, have been making some experiments in puddling blast furnace metal which have been very successful. There are now six puddling furnaces in use on this process. No changes were made in the puddling furnaces, except to put in a trough to carry the liquid metal into the furnace from the ladle. The liquid metal is brought from the blast furnace into the puddle mill by a small locomotive. The track is so laid that the top of the ladle when on the truck is a short distance below the level of the pig bed in the casting house. The ladle holds 4400lb., which is enough to charge two puddling furnaces. Each furnace is worked through four doors by four men, and is of four times the capacity of the single furnace. The 2200lb. of metal require about an hour for the complete process, making ten balls. The time required for the five heats of a shift is now seven working hours, and two shifts are made a day. The blast furnace itself is working very well, although tapped once an hour for the metal for the puddling furnaces. Once a day the surplus metal is run into pigs, which seem to be of as good a quality as before the direct puddling process was introduced. The saving thus far has been about one-fourth the fuel (Indiana block) used by the old process, at the same works. The metal is obtained very much clearer than heretofore. The muck bars work very well in the rolls, and seem to be of as high a quality as could be desired, and at no stage in the operation does there seem to be any trouble from the new process.

Canals.—A vote of £296,000 is asked by the Canadian Government to increase the depth of the St. Lawrence canals to 14ft., and of £200,000 for the canal at Sault Ste. Marie. A canal has been proposed between Lake Michigan and Lake Superior, the estimated cost being £1,000,000; but thorough surveys have not been made.

IMPROVED EXPANDING PULLEYS.

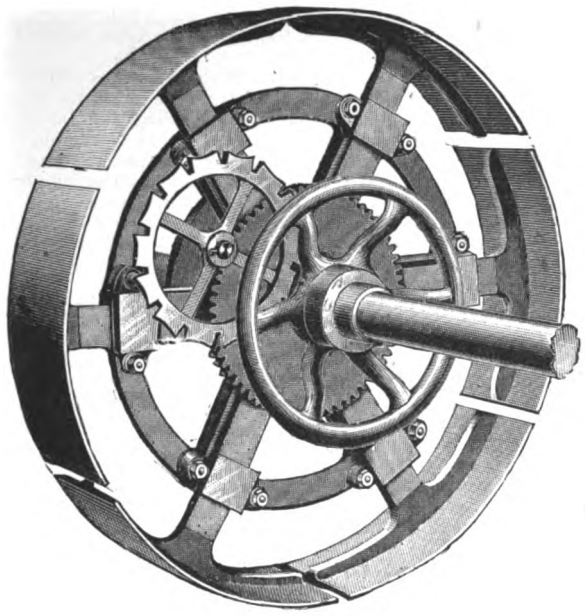

FIG. 1.

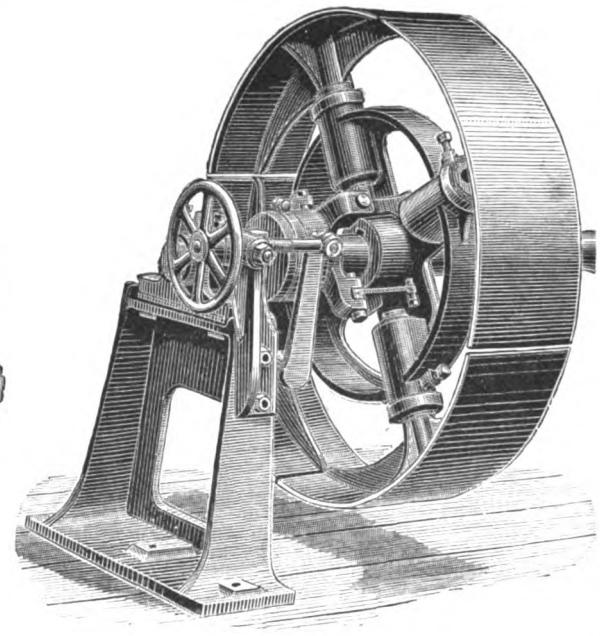

FIG. 2.

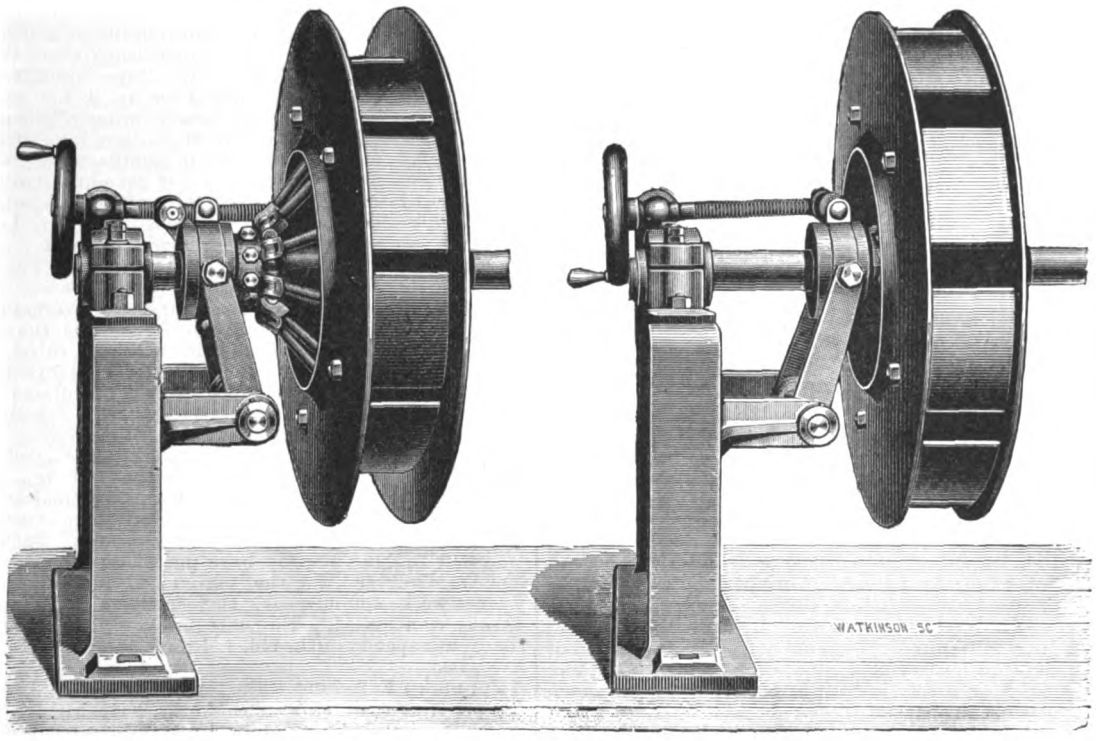

FIG. 3.

IMPROVED EXPANDING PULLEYS.

THE above illustrations show some improved expanding pulleys made by Messrs. Bentley & Jackson, engineers and iron founders, Bury, near Manchester. The pulley shown in Fig. 1 is intended for machines where exactitude of speed is required, or where the relative speeds require adjusting to suit the nature, moisture, or temperature of the material operated upon. The diameter of this pulley can be increased or decreased as desired, the total variation being about 2in.; the change is effected by moving the hand wheel shown in the illustration. The segments of the pulley themselves slide in brackets, and are actuated by the hand wheel just referred to. Fig. 2 represents another example of an improved expanding pulley by the same makers. This pulley is constructed so that its diameter may be increased or diminished whilst the pulley is in motion. The movement requires but little effort, and is made without any danger. This pulley may be applied to machines where small adjustments of speeds are frequently required; the change in size is effected by moving a hand wheel in connection with a screw and levers, as shown in the illustration. The four segments of this pulley when thrown out to the required size can be fixed in their place by set screws, tapped into bosses which form part of the inside fixture. Fig. 3 shows a pulley of the "umbrella pattern." This pulley can also be increased or diminished in diameter while in motion, the total variation obtainable being about 6in. The illustration represents the pulley as seen at its greatest and least diameters; the variation is effected by means of the hand wheel and screw. The nut on the hand wheel screw is attached by means of an iron strap to the sliding bush. The bush has two levers to keep it in its place, attached by carriers to the upright pedestal; on the bush are also coupled several knuckle bolts, fastened at the other end to the segments of the pulley. The hand wheel on being turned forces the bush towards the pulley and expands the segments between the parallel discs, the discs thus forming flanges to the pulley.

SPANISH RAILWAYS.—For the last thirty-three years the Spanish Government has encouraged the building of railways by paying subsidies during the progress of laying down the line. A Bill has, however, now been introduced which will alter this arrangement, and which is intended to develop secondary lines of one-metre gauge. It is proposed to assist these by guaranteeing the payment of 5 per cent. interest on the capital invested. The cost is not to exceed £3,200 per kilometre. It is expected that the passing of this Bill will give a great impetus to the construction of lines of this nature.

THE ADMIRALTY PROGRAMME.

IN a previous issue we considered some of the more general questions connected with the Navy Estimates. In this we propose to give an outline of the more strictly engineering and shipbuilding programme which the Admiralty has proposed for the current year. But first we may glance at the increase which was made to the fleet in 1887-88. At the beginning of that year it was anticipated that during its course twenty-five ships, having an aggregate displacement tonnage of upwards of ninety thousand tons, would be completed and passed into the First Reserve as ready for service in forty-eight hours. Of these ships ten were armoured, two protected, and thirteen unprotected. This programme has been very nearly realised, and would have been actually carried out but for delays in the delivery of contract built ships, the non-completion of guns by the promised dates, and the difficulties that have arisen in completing some of the contractors' steam trials. Among the armoured ships were five belted cruisers, two of which are now practically complete, and one of these, the "Orlando," is to be the new flagship on the Australian station, and the remaining three, for the reasons given above, will have to be completed in the earlier months of the financial year 1888-89. The "Rodney," "Benbow," and "Hero" are complete, except for gun trials and certain modifications of torpedo net defence. The "Warspite" and the "Howe" are also practically complete. All the protected and unprotected vessels will be completed as proposed in 1887-88. These fifteen vessels include two protected eighteen knot cruisers ("Mersey" class), seven torpedo cruisers ("Archer" and "Fearless" class) of seventeen knots, three torpedo gunboats ("Rattlesnake" class) of nineteen knots, one composite sloop, and two gunboats. The completion of the "Archer" had to be deferred to 1887-88 on account of steam trials, so that sixteen vessels will have been practically added in that financial year. In addition to ships completed during the year, a large amount of work has been done in advancing other new ships, as yet incomplete. The armoured ships "Camperdown," "Anson," and "Immortalité" are rapidly approaching completion, and good progress has been made with the protected cruiser "Forth," the last of the "Mersey" class, and the "Aurora," the last of the belted cruisers; while the progress of the "Trafalgar" and "Nile" has been exceptionally rapid, and it is believed that the former will be completed in the year 1889-90. Of the new vessels laid down in 1887-88 in the dockyards, the two twenty knot protected cruisers building at Chatham have been pushed forward nearly to the stage of launching; the similar but sheathed cruiser at Portsmouth has been advanced considerably beyond what was contemplated in the Estimates for 1887-88. The two composite sloops ("Nymphe" and "Daphne") are almost ready for launching, and the six gunboats of the "Pheasant" class have been advanced as was intended. Moreover, during the year four ships not contained in the Estimates were laid down. These vessels were required for relief and special service, and consisted of three gunboats and a paddle steamer for surveying service.

The work being done by contract in 1887-88 has also very nearly kept pace with the programme. Of the five belted cruisers the "Orlando" and "Undaunted" were delivered within the contract time; the remaining vessels were not delivered until the contract times had been exceeded. The "Victoria," formerly "Renown," is expected to be completed six months within the guaranteed time, and the sister ship "Sanspareil," it is anticipated, will also be delivered within the period allowed by the contract. The completion of these two powerful ironclads will bring to an end the special programme of 1885 originated by Lord Northbrook, so that it may be anticipated that the expenditure involved in carrying out that programme will be almost concluded during the year 1888-89. During the year 1887-88 the only new vessels ordered by contract were the sheathed protected cruisers "Magicienne" and "Marathon," which are being built by the Fairfield Company, Glasgow, the engines being supplied by Messrs. Hawthorn, Leslie, & Co. The Admiralty officials acknowledge the assistance and co-operation of the most emiment private firms of marine engineers who have contracted for the machinery, and this has led to the design and construction of engines of ever increasing power and the introduction of successive improvements, and they are of opinion that the decision to adopt triple expansion engines has been amply justified by the results so far attained. In not a few cases the engine power and speeds estimated in the stage of design have been considerably exceeded on trial.

During the year 1887-88, twenty first class torpedo boats have been built, and at the close of 1887-88 we shall possess eighty first class torpedo boats and sixty-three second class boats, of which latter twelve are built of wood and fifty-one of steel. The Board of Admiralty have been supported in their decision to discontinue the building of torpedo boats for sea-going purposes, and to substitute

Digitized by Google

vessels of a much larger displacement, similar to the torpedo gunboat "Rattlesnake," which has been an undoubted success. Accordingly, a design has been approved for a larger and swifter vessel than the "Rattlesnake," and one—the "Sharpshooter"—has been provided for in the Estimates of 1887-88, and has been commenced at Devonport, and arrangements have been made for building six other vessels of the type at Devonport and Chatham in 1888. After completing the seven armoured ships above mentioned, there will remain in hand the following armoured vessels when the next financial year closes: "Victoria," "Sanspariel," "Aurora," "Nile," "Trafalgar;" and of these the first three will be approaching completion, while considerable expenditure will still have to be incurred on the "Nile" and "Trafalgar." The Board have therefore decided not to lay down during 1888-89 any new ironclads. They propose, however, to re-engine the "Superb" and the "Thunderer," and re-arm the latter, and to build the following new vessels: Protected ships—first class cruisers, two; torpedo depôt ship and torpedo boat cruiser, one; third class cruisers, steel bottomed, two; sheathed and coppered, four. Unprotected ships—Sloops ("Buzzard" type), two; gunboats ("Rattler" type improved), six; torpedo gunboats ("Sharpshooter" type), six; sailing brig (training boys), one—total, twenty-four. All these vessels, with the exception of one first class and one third class cruiser, and two composite gunboats, will be built in the dockyards. There are, however, in addition the seven vessels intended for service in Australasian waters, consisting of five protected cruisers (new design), and two torpedo gunboats ("Sharpshooter" type). These it is proposed to construct by contract. The total number to be laid down is thirty-one, comprising an aggregate displacement of sixty thousand tons, and it is estimated that the following is the amount of displacement tonnage which for the three years ending April, 1890, will be passed into the fleet ready for commission: 1887-88, seventy-five thousand; 1888-89, seventy-seven thousand; 1889-90, seventy-five thousand.

The memorandum which has been issued along with the Navy Estimates states that the programme of new construction to be undertaken in the coming financial year has been most thoroughly considered and discussed by the Board, and that in framing it, full consideration has been bestowed upon the requirements of the fleet in relation to reliefs, the various special services required of Her Majesty's ships on foreign stations, and the "waste" of the navy resulting from ships becoming obsolete through age or the progress of invention. A careful examination was also made into the composition of the squadrons abroad, and a standard of strength was fixed, both for reserves at home as well as for stations abroad, up to which the fleet should always be maintained, and the condition and character of the ships already in progress, as well as their state of advancement, have also been kept in view. Moreover, a careful examination has also been made of the shipbuilding policy now being pursued by foreign navies, the progress made on ships yet incomplete belonging to these navies, and the liabilities yet remaining to be discharged. The consideration of how far the Board has in our opinion been successful in carrying out their intentions, and also of the designs which they have made for the various classes of ships, must be left for a future occasion.

THE FORTH BRIDGE.

We illustrate this week, on page 348, the crane specially designed for building the top members of the Forth Bridge, as it stood complete in the building yard before being removed to its working position. The illustrations accompanying Mr. A. S. Biggart's paper in our last week's issue very clearly illustrate the application of this crane to the erection of the bridge. It consists of a 3-ton steam crane, with a boiler 4ft. 6in. diam. by 8ft. high, working at a pressure of 40lb. per square inch. The winch engine has two cylinders of 7in. diam. by 11in. stroke, and the lifting drum is 2ft. diam. The jib is of steel, 35ft. long, and capable of moving through an angle of 230°. The hoisting cable passes over a pulley, carried by a cradle which travels along the horizontal boom of the jib; thus while it can raise its load 200ft., it can also, if necessary, simultaneously move it backward or forward through 35ft. The crane is mounted on cross girders, resting on both top members, and the frame work is all of steel. On a bracket, fixed to the cross girders behind the steam crane, there is a hydraulic crane, with a jib 27ft. long, worked by a 4in. ram, at 1000lb. pressure per square inch. This crane carries the riveting machine, and has a lift of 6ft. with a 3-ton load. Suspended by angle bars from the frame work of the crane are four box lattice girders, carrying a staging 76ft. by 45ft. for the men working immediately under the top member. The whole crane with its staging weighs 58 tons, and when the outer jib has plated a section and the inner jib has riveted one, it is slipped down over the completed portion to commence a new section.

Notices of Meetings.

THIS WEEK.

Geologists' Association.—Friday, 6th April, 8 p.m. Papers to be read on "The Influence of Geology on the Early Settlements and Roads," by Mr. F. J. Bennett, F.G.S.; and on "The Discovery of Elephas primigenius associated with Flint Implements at Southall," by Mr. J. Allen Brown, F.G.S.

NEXT WEEK.

Society of Arts.—Monday, 9th April, 8 p.m. Cantor lecture on "Milk Supply, and Butter and Cheese Making."—Wednesday, 11th April, 8 p.m. Ordinary meeting. Paper to be read on "Recent Legislation concerning the Pollution of Air or Water," by Mr. Alfred E. Fletcher, Chief Inspector of Alkali, &c., Works.—Friday, 13th April, 8 p.m. Indian Section. Paper to be read on "The Experiences of Twenty Years in Conducting Agricultural Inquiries in Southern India," by Mr. W. R. Robertson, M.R.A.C.

Society of Chemical Industry.—Monday, 9th April. Paper to be read on "The Present Position and Prospects of the Coal Gas Industry," by Mr. Lewis T. Wright.

Royal Institute of British Architects.—Monday, 9th April. Ordinary meeting. Ballot for new members. Discussion of any professional questions, &c.

Institution of Civil Engineers.—Tuesday, 10th April, 8 p.m. Paper to be read on "Compressed Oil Gas and its Applications," by Mr. Arthur Ayres, M.Inst.C.E.

Civil and Mechanical Engineers' Society.—Wednesday, 11th April. Paper to be read on "Theatres and other Public Buildings," by Mr. Walter Emden.

North-East Coast Institution of Engineers and Shipbuilders.—Wednesday, 11th April, 7-30 p.m. Adjourned discussion on Mr. J. T. Milton's paper on "Slide Valve Gears." Adjourned discussion on Mr. G. W. Sivewright's paper on "Stockless Anchors and Fittings." Paper to be read on "The Construction of Pontoon Dry Docks," by Mr. A. Taylor.

Royal Institution of Great Britain.—Thursday, 12th April, 3 p.m. Lecture on "The Chemical Arts," by Professor Dewar.

Society of Telegraph Engineers and Electricians.—Thursday, 12th April, 8 p.m. Paper to be read on "Central Station Lighting (Tranformers v. Accumulators)," by Mr. R. E. Crompton, M.Inst.C.E.

Physical Society.—Saturday, 14th April, 3 p.m. Papers to be read on "The Measurement of the e.m.f. of Dynamos," by Professor W. E. Ayrton, F.R.S., and Professor J. Perry, F.R.S.; "The Variation of the Co-efficients of Induction," by Mr. W. E. Sumpner, B.Sc.; "Some Experiments on Soap Bubbles," by Mr. C. V. Boys; and "Electromotive Forces by Contact," by Mr. C. V. Burton, B.Sc.

PRICES CURRENT, 5th April.

Quotations at per ton, unless otherwise specified.

Messrs. Carrick & Brockbank, Manchester, report as follows:—

Copper.—During Easter holidays Chili quotations have been very steady at £80 to £80. 10s. per ton for Gobs, at which a moderate business has been done for sharp cash parcels. Three months is held for £79. 12s. 6d. to £79. 15s. Manufactured is still slow of sale, both for home and export.

Tin.—Spot parcels continue to find buyers at £166 per ton, and a fair business is reported thereat. Forward delivery varies according to date, full three months down to £125 per ton, with buyers rather than sellers.

Lead.—Spanish is quoted £14 to £14. 5s. per ton.

Spelter.—Quotations are unaltered.

COMPOUND TELEPHONE AND TELEGRAPH WIRES.

An old idea, first tried in America some years ago, has been revived by Messrs. Kareis & Bondy, Vienna, who have patented iron or steel wires covered with a spiral serving of copper wire or ribbon of very small thickness. These wires are now being tested at the laboratory of the Electrotechnical Institute in Vienna, and have so far given fairly good results. The object of the invention is to provide aërial wires having less self induction and resistance than ordinary iron or steel wires, without sensibly diminishing the mechanical strength. The wire is intended for use with currents of rapid period, such as occur in telephony or in high speed telegraphy, and as through self induction the flow of current is displaced from the centre to the circumference, the inventors argue that it would be useless to make the centre of a material having a high conductivity.

HOME INDUSTRIES.

MANCHESTER, 5th April, 1888.

The Metal Trade.—In consequence of the holidays very little business has been done, and makers are so well sold that there is not much forcing of business on their part. A steady demand is experienced, and, generally speaking, there is no slackness at the works. The prices of pig iron are practically stationary, and are not expected to go much lower. No great business in wrought iron is expected until after the results of the iron masters' quarterly meetings have become known. These will be held next week, and it is not probable that any material change will be made in the state of trade so far as quotations are concerned. At present iron bars are quoted at £5. 2s. 6d. per ton for delivery in this district, but can be purchased for less. A fair trade is being done in steel bars for shafting purposes. In a recent specification for steel shafting, the steel used was specified to have a tensile strength of 28 tons, with 30 per cent. contraction of area and ·346 per cent. of carbon. This is a test which may cause some difficulty. Other steel goods, such as plates for boiler purposes, are in good demand, and are being very freely sold. The continued high price of copper is having the effect which was looked for. Many large users are trying other metals in place of it, and it is in consequence very difficult to effect sales of any large amount. In all departments in which copper and brass are used this contraction is taking place, but signs are not wanting that people are getting accustomed to the prices, and are disposed to order somewhat more freely.

The Engineering Trades.—During the holidays there has been a little more business doing in repairs, but with this exception there is nothing special to note. In Bolton the engineers are fully employed, as is the case generally in the larger centres. The trade which is being done is principally with the East, as our Continental trade is now much reduced by German, French, and Belgian competition. Boiler makers are still fully employed, although prices have been considerably reduced. Tool makers are not finding much improvement, and competition for orders is very keen. Cotton machinists are still fully employed, and to all appearances will continue to be so for some months to come. Spinning continues to be profitable, and many orders for replacements are being given. Any orders for new mills are coming principally from India, Japan, Brazil, and Mexico, and with all these countries a fair trade is being done. In the miscellaneous and special businesses, such as brass founding, a moderate amount of work is being done.

The Hat Trade.—During the past few months a series of lectures has been delivered to the Hat Manufacturers' Association, by Mr. Watson Smith, F.C.S. These lectures have been of great value, and have attracted considerable interest. The greater knowledge of the art of dyeing, consequent on careful chemical training, has enabled the Germans to secure a large proportion of the business. From this point of view the value of the lectures cannot be over-estimated. It is, however, gratifying to record that this competition is being at present effectually met, and that in the more delicate shades of colour great progress is being made and an increasing trade done.

The Silk Association of Great Britain and Ireland.—A meeting of the provisional committee of this Association was held at Manchester, on Thursday, the 29th ult., Mr. Thomas Wardle, the President, in the chair. A code of rules was adopted, in which the objects of the Association were stated to be as follow: The promotion and maintenance of the silk industry of Great Britain and Ireland in all its branches; to encourage the production of raw silk in India and the Colonies; to collect and disseminate among the members useful information and statistics connected with the manufacture of and commerce in silk; and to promote technical education and parliamentary legislation on subjects affecting the silk industry. The membership is to be open to all silk manufacturers, merchants, dyers, and finishers; and any Chamber of Commerce may become affiliated with the Association, and have the power to appoint a representative to sit on the Council every year.

LONDON, 5th April, 1888.

The Money Market.—The incidence of the Consols settlement, which was naturally heavy on account of dealings due to the Conversion Scheme, caused money to be in fairly good demand at the close of the holidays this week. Rates remain very much as they have been for a time past. The Stock Exchange took some little time to get fairly into the run of business after Easter, and the tone has been rather languid since. The markets re-opened with a distinctly better disposition, but there was no substantial support to it. There have been signs of a renewal of the activity in copper shares, and American railways show an inclination, though not sustained, to make good the expectations long entertained of an improvement in them. Home railways are fairly buoyant.

Companies.—During the past month there were registered 209 companies, with an aggregate capital of £17,804,400. Since our last report, the following new companies have been registered: Thomas Turner & Co., Limited, with a capital of £60,000, to carry on the business of glass bottle manufacturers; the Mysore Reefs Company, Limited, with a capital of £150,000; the Troy Gold Mine, Limited (North Carolina), with a capital of £20,000; Spreacombe Vall Mine, Limited, with a capital of £30,000; Spirometer Company, Limited, with a capital of £10,000; the Egyptian Lakes Reclamation Company, Limited, with a capital of £300,000; Felix Hadley & Co., Limited, with a capital of £70,000, to acquire a nail, tack, staple, and rivet manufacturing business in Birmingham; James Davies & Co., Limited, with a capital of £10,000, to purchase an ironmonger and hot water engineer's business at Croydon; John & Samuel Taylor, Limited, with a capital of £30,000, to acquire a cotton spinning business at Oldham: Jacoby Brothers & Co., Limited, with a capital of £50,000, to acquire a lace manufacturing business; the Goldfields of North Queensland, Limited, with a capital of £100,000; and D. Watney & Son, Limited, with a capital of £200,000, to carry on business as brewers, &c.

Copper.—The stocks of copper in England and France at the close of last month are given by Messrs. Henry R. Merton & Co. at 51,797 tons, or with the quantities advised from Chili and Australia, 58,747 tons. At the close of February, the figures were 44,943 tons and 52,593 tons, so that there has been a considerable increase in the stocks in hand.

Chemicals.—Business in chemicals is dull, and prices generally show a tendency to fall. Bleaching powder, soda ash, and most qualities of caustic soda are lower, and ammonia salts are weak. Carbolic acid is firm, though there is but little inquiry. The prices obtained for sulphate of copper are considerably lower than the nominal quotations.

Wool.—The second series of Colonial wool sales commences to-day, and will last till 15th May. Since the last series the tone of the market has been somewhat depressed; but Continental reports having been more favourable, greater firmness is now shown, and there is more inquiry for tops.

Produce.—Business in the sugar market has been very quiet, and prices are rather weaker. Coffee shows a heavier sale, and better rates have been obtained. Rice is in better demand.

Railways.—The gross receipts of the twenty-three principal railways in the United Kingdom for the week ending 25th March, amounted to £1,104,462 on 15,850¼ miles, as compared with £1,127,196 in the corresponding period of 1887, when the mileage was 15,708¾ miles. An increase is thus shown in the mileage of 141½ miles, or 0·8 per cent., and a decrease in the receipts of 2 per cent.

The Sugar Bounties Conference.—The International Conference on Sugar Bounties is to re-assemble to-day at the Foreign Office, under the presidency of Baron Henry de Worms. The London Trades Council has passed a resolution condemning the bounties as an attack on free trade principles.

The Navy.—The "Benbow," built by the Thames Iron Works Company, and delivered by them in October, 1886, was completed for sea on Saturday. She is 325ft. in length, has a displacement of 10,600 tons, and carries two 110-ton guns. Her engines are of 11,500 h.p., and she can steam 17 knots an hour.

The North Baltic Canal.—The Foreign Office announces that the Imperial North Sea and Baltic Canal Commission have invited tenders for the supply of two steam dredgers and seven steam barges for use in the construction of the North Baltic Canal. The conditions of tender can be obtained upon payment of two marks, in cash or by postal order, to the Imperial Canal Committee, No. 61, Muhlinsstrasse, Hamburg.

Registration of Firms.—The proposal which Sir Albert Rollit, M.P., has placed before Parliament for the compulsory registration of firm names provides that every firm carrying on business under a name not consisting of the full or usual names of all the partners or all the acting partners shall be registered. The register is to be kept by the registrar of joint stock companies, who will send abstracts of the statements to the registrars of county courts in whose district the places of business are. The statements thus registered are to be open to anyone's inspection on payment of a small fee.

Factories and Workshops.—The report of Mr. Redgrave, C.B., the chief inspector of factories and workshops, for the year ended October 31st, 1887, has been issued as a Parliamentary blue book. There is also supplemental information from other inspectors on the state of trade, wages, the sweating system, and the employment of children. Mr. Henderson, inspector of Scotland and the four northern counties of England, gives a table of wages in the shipbuilding trade, from which it appears that they were at their highest in 1882, when the largest tonnage on record was launched. In 1881 a fitter could earn £1. 9s. 3d. a week; in 1882, £1. 11s. 6d.; while the amount has gradually sunk since, until in 1887 it was £1. 4s. 9d., a reduction of 15 per cent. in six years.

Exhibitions.—Nearly 3000 applications have been received for space at the forthcoming Italian Exhibition to be held at Brompton. Venetian glass blowing and the Tuscan straw industry will be represented.—An Anglo-Danish Exhibition is to be opened early next month at South Kensington.

GLASGOW, 5th April, 1888.

General Business.—The coincidence of Easter Monday with the Glasgow Spring Holiday has caused an extreme slackness during the early part of the week. On Tuesday and Wednesday there was comparatively little being done in any of the markets. During the past week pig iron shipments were fairly brisk, the total showing an increase over the corresponding period last year of about 50 per cent. Coal shipments on the other hand fell from 71,775 tons to 66,372 tons.

Shipping Trade.—The quarterly report of the Clyde shipping trade shows that 326 vessels, of an aggregate tonnage of 305,594 tons, arrived in the river from foreign ports during January, February, and March. This is a falling off of upwards of 25,000 tons as compared with last quarter. The quarter ending in December last was, however, an exceptional one, the arrivals being 366 vessels of 330,862 tons. The returns of the first quarter of this year shows an increase over those of last year of 25,000 tons, and over those of 1886 of 31,000. The departures to foreign ports from the Clyde during the quarter were of considerably greater tonnage than the arrivals, though relatively to the periods with which the arrivals are compared above, they show much the same variation from the figures of previous years. The total of foreign departures for the quarter just closed was 390,913 tons, against 424,093 tons for the December quarter, 1887, and 334,643 tons for the March quarter, 1887, and 300,888 tons for the March quarter of 1886. The value of the exports has in the important items been nearly maintained. Cotton goods, though less in total value than they were in the March quarter of 1887, are fully 10 per cent. more than in the December quarter. Linen has increased by 50 per cent; steel has decreased from £106,000 to £78,000. Iron is less in total value, and general machinery shows a falling off of about 15 per cent.

Shipbuilding.—Messrs. Wm. Hamilton & Co., Port Glasgow, have booked a contract for a sailing vessel of 2000 tons. Contracts for new vessels are being placed very slowly, the demand that sprang up towards the close of the year having apparently expended itself.

Extensive Raid upon Alleged Smugglers.—The Customs authorities at Greenock have effected the capture of a large quantity of contraband tobacco, and have apparently put a stop to the most extensive and ingenious system of smuggling that has been discovered for some time. In carrying on this contraband traffic, the tobacco was packed in cases and hermetically sealed, and was shipped to the Clyde by a steamer or steamers. When a vessel containing the contraband cases arrived in the Firth of Clyde, the cases were attached to long lines, to which were also attached cork floats. The freight was then thrown overboard, and boats from the shore, while ostensibly engaged in deep sea fishing, secured the tins during the night. The tobacco was then landed by the boats upon an unfrequented part of the coast, where a cab waited to convey the contraband goods to Greenock. The quantity seized has been about half a ton; but it is understood that the traffic has been going on for a long time, and that elaborate arrangements for disposing of the tobacco existed throughout the country. The number of persons necessarily implicated in so large a scheme has been fatal to its continuance, for it is understood that the discovery has been made by the aid of an informer. A number of arrests have been effected, and the prisoners will in due time be tried at Edinburgh.

(From our own Correspondents.)

LIVERPOOL, 4th April, 1888.

The New Brighton Railway.—The remaining portion of the new line from Wallasey to New Brighton was inspected last Thursday by Major-General Hutchinson, on behalf of the Board of Trade, and passed for traffic. Passengers can now travel from the James'-street Station, in Liverpool, to New Brighton, without changing, and there will consequently be sharp competition between the railway company and the Ferry Commissioners for the immense summer traffic to this favourite resort. The railway has a double line throughout; it leaves the Hoylake Railway at the Docks Station, takes a long curve through Bidston Marsh, reaches Wallasey Station at the foot of Grove Road; it then passes through the sandhills to Warren Down Station—not yet completed—and on through a deep cutting in the red sandstone between Victoria Road and the river, to the terminus at Atherton-street, in New Brighton. On Good Friday over 4500 passengers travelled along the new line, and though a large proportion of these would be travelling for curiosity, there is no doubt that the line will be well patronised in the future. The engineer for the line is Mr. Francis Fox, M.Inst.C.E.

Trial of a New Patent Marine Engine.—A novel marine engine and steam generator has been patented by Mr. Henry Turner, of Liverpool, and one constructed on this principle by Messrs. George Bayliff & Son, Wirral Foundry, Birkenhead, was recently tested in the presence of a large number of engineers and others interested in the question. Steam at a high pressure is used on the atmospheric principle, and it is so arranged that the walls of the cylinders, pistons, &c., are heated and maintained at a temperature equal to that of the steam by means of heated air, which is admitted to and expelled from the atmospheric end of the cylinder by each stroke of the engine. The air for the above purpose is heated by the waste gases from the steam generator, and taken from a receiver in the uptake by the engine, thus forming an automatic forced draught. The engine was single acting, with one crank; the cylinders were 6in. and 17½in. diam. respectively, and 10½in. stroke. The total heating surface of the boiler was 88 sq. ft. With steam at 225lb. and 300 revolutions, 65 h.p. was indicated, with an extremely small consumption of coal.

SHEFFIELD, 4th April, 1888.

Iron and Steel.—Most of the heavy material producing works have been closed for the Easter holidays. Considerable satisfaction has been felt in Sheffield at the result of the armour plate trials at Messrs. Cammell & Co.'s Works. The resistance of their compound plate to the chilled forged steel projectiles was exceedingly satisfactory, and it is not improbable that the other local firms in the competition will come well out of the ordeal. Messrs. John Brown and Co., Messrs. Vickers & Co., and Messrs. W. Jessop & Sons, have sent carefully made plates, either compound or of solid steel, and it is believed that the decision of the experts will result in very remunerative orders to one or other of these Sheffield houses.

Coal.—A satisfactory trade is being done in nearly all sorts of coal, and new collieries are being opened out. One of these is at Dronfield, where Mr. Sheard, colliery owner, has bought the coal under 100 acres, and is making arrangements to work it. The coal owners of South Yorkshire are looking forward with great interest to the coming fight before the Committee of the House of Lords against the Midland Railway Company, who are seeking to work the Hull and Barnsley Railway. The latter line has been taking coal to the port at a reduction of 6d. per ton. The Midland have declined to give a guarantee that they will continue to convey the coal at the reduced rate, and the coal owners are up in arms, especially as 6d. per ton on 1,790,000 tons—the amount sent last year—is well worth fighting about. Since the reduction from 3s. 1d. to 2s. 7d. per ton, the coal traffic to Hull has enormously increased from the South Yorkshire coal field, the tonnage in 1884 being 1,300,000 tons.

LEEDS, 4th April, 1888.

The Heavy Industries.—Trade in heavy material continues satisfactory in Leeds. The demand for iron and steel is still extensive, and the engineers are busy in nearly all departments. The bulk of the work turned out has not been so great during the past few days owing to the holidays; but makers of Bessemer and iron founders have good orders on their books. Heavy machinery for ships, pumping, and colliery purposes is in greater demand, and agricultural machinery, which for some time past has been nearly a drug on the market, is selling more freely. Railway material is in demand, chiefly on foreign account, and one or two profitable lines are on hand for axles and tyres. Engines, both locomotive and stationary, are in slightly better request; and for tram work the supply is extending. The tram engines now in use in Leeds are not handsome; and it is surprising that in these days of scientific and industrial enterprise something more comely has not been designed. Appearance has been more considered in the construction of the cars; and a few days ago, a new car, built by Mr. Milnes of Birkenhead, made a trial trip from Boar Lane to Kirkstall. The car, which is on the bogie principle, is comfortable, prettily decorated, and is fitted on the top with seats having reversible backs. It is an improvement on the old style of vehicle, and will no doubt give great satisfaction on the Headingley and Wortley routes. Fencing and roofing are more eagerly inquired for; and for engineers' tools the call is brisk. Cut nails find a ready market; and the iron and steel industries generally are in a healthy condition.

NORTH STAFFORDSHIRE, 4th April, 1888.

The Iron Trade.—The holidays are in full operation, and most of the mills and forges are still standing. In some instances work will be resumed to-day, but in others the works will lie idle until Monday next. There is a general feeling of despondency amongst members of the trade, and no appreciable improvement is anticipated under any circumstances until the autumn. Contracts for pig iron have recently been entered at prices below the level of 1887, and some 4s. per ton below the rates quoted at the January quarterly meetings.

The Coal Trade.—Considerable difficulty has been experienced in supplying current requirements during the past few days. Owing to the continued severity of the weather fuel has been in great demand, and it is always impossible to get colliers to work during holiday time.

North Staffordshire Miners' Permanent Relief Society.—The annual meeting was held at Stoke on Monday last. On account of certain reductions in the benefits allowed to members, made on the recommendation of the actuary who was called in to investigate the financial position of the society, over 1000 miners seceded from membership last year, and at the close of 1887 the number on the books stood at 4172. The income for the year amounted to £3,961. 10s. 9d., and the expenditure to £3,626. 2s.

SOUTH WALES, 4th April, 1888.

Mannesmann Tube Works.—The process for the manufacture of metal tubes, which was described in last week's issue of *Industries*, is being introduced into Swansea. Messrs. Krupp & Mannesmann have taken the old steel works at Landore recently vacated by the Siemens Company. It is intended to manufacture both steel and copper tubes by the Mannesmann process.

Reduction in Railway Rates.—A substantial reduction in the carriage of coal from the Monmouthshire valleys to Cardiff has been made through a working arrangement recently arrived at between the Great Western and the Taff Vale Railway Companies. In the case of one large colliery firm the concession will result in a saving of 5d. a ton on all coal sent to the East Dock.

Strike at the Panteg Works.—The strike at Messrs. Wright & Butler's Elba Works has extended to the works at Panteg belonging to the same firm. The customers have hitherto been kept together by the supplies from the latter place; but the firm will now have to take into serious consideration the question of the advance of wages demanded by the men.

BARROW-IN-FURNESS, 4th April, 1888.

Iron and Steel.—There is a steady tone in the hematite pig iron trade of this district, and the improvement noted last week is fully maintained. There is an improved demand for both Bessemer and ordinary hematite qualities of pig iron, and makers are becoming more and more firm in their transactions. They are already very well off for orders, and are beginning to experience the advantage of a growing shipping trade. There is a steady market in ordinary forge, but the trade in Bessemer is continually growing as the wants of steel makers are increasing. Last week's quotations for pig iron are adhered to, and it is believed that after the Easter holidays the demand will so improve on local, general, and Continental account as to enable makers to secure more than present rates, viz.: 43s. 6d. for Bessemer in parcels of mixed numbers, or 42s. 6d. for No. 3 forge and foundry iron. Stocks of iron are large in the hands of holders and merchants generally, and it is evident that these will remain so long as prices are as low as they are at present. There is a brisk tone in the steel trade, and the demand for rails is still very active; £4 per ton is the quotation for heavy sections. A continuance of the better trade in steel for shipbuilding purposes is maintained, and plates are quoted at £7 per ton, and angles at £6. 10s. net f.o.b. Billets and bars are in full demand.

A New Gas.—The Local Board of Dalton-in-Furness recently determined to experiment at Askam-in-Furness with a new gas for the purposes of street lighting, house illumination, &c., and with this view put down a Stockport patent apparatus for the production of gas from scrap iron and sulphuric acid. The new gas was produced on Good Friday for the first time, and the streets were brilliantly lighted. The light is bright and steady, and of great illuminating power. So far as can be seen the novel experiment is a great success; but experience alone can determine whether it will prove financially economical. The patentees, however, claim that it is much cheaper and more effective than ordinary coal gas.

MIDDLESBROUGH, 4th April, 1888.

Pig Iron.—The Easter holidays have brought business to a standstill, but the market is very firm, and the price is maintained at 31s. 6d. for early delivery. The exports of pig iron for the month of March amount to 79,465 tons, being the highest monthly record during this or last year. Of these 43,265 tons went coastwise, and 36,200 tons foreign. The increase was chiefly in the foreign exports. The shipments for the first quarter of the year amount to 207,553 tons, as against 172,388 tons for the first quarter of last year.

Wrought Iron and Steel.—There is little or no change in wrought iron and steel. The finished iron makers are asking for orders at lower prices than they have been satisfied with for some time back. The work at the foundries is rather slack, and full advantage of the holidays has accordingly been taken.

Iron and Steel Shipments.—On Saturday night, the return of shipments of pig and manufactured iron and steel for the month of March were issued by the Middlesbrough Customs officials. The total of all kinds was 112,961 tons, being an increase of 10,186 tons over the quantity shipped in the preceding month, 3673 tons of the additional quantity being sent coastwise, and the rest abroad. Of pig iron 79,465 tons were shipped, being 12,565 tons more than in February, the coastwise shipments being 3361 tons more than in the previous month. The remaining 9000 tons went abroad. Holland took 11,861 tons, France 4050 tons, Belgium 3900 tons, Germany 6695 tons, Japan 2770 tons, Sweden 1549 tons, and the United States 1690 tons. No other country took a thousand tons. Of manufactured iron 20,853 tons were shipped, being 437 tons more than in February, and this was wholly in the coastwise shipments, there being a decrease in the quantity sent abroad. Of the 13,868 tons sent foreign India took 8727 tons, Japan 1796 tons, Argentine Republic 1120 tons, and Spain 999 tons. Of steel 12,643 tons were shipped, being 2926 tons less than in February. The foreign shipments of this article showed a falling off of 2176 tons, our only customers abroad during the month being India and the Argentine Republic, the former taking 9764 tons, and the latter 740 tons.

SUNDERLAND, 4th April, 1888.

Shipbuilding.—Just before the holidays a few additional orders were placed with local shipbuilders. During the quarter ending March 31st there have been 16 vessels of 29,771 tons launched by eight shipbuilders on the Wear, including fifteen steamers of 28,317 tons, and a sailing vessel of 1,454 tons.

Shipping.—During the last week the shipments of coal were above the average; 92,368 tons were shipped for home and foreign ports, being 35,009 tons in excess of the previous week. There was also a fair quantity of coke, patent fuel, fire bricks, cement, lime, bottles, &c., shipped. The import trade was also brisk, including 5050 bales of esparto grass, 69,094 pit props, besides considerable quantities of deals, pitch pine, &c., together with twenty-six cargoes of wheat, oats, &c., from home ports. Freights on the whole are better, and there is little unchartered tonnage. It is reasonably anticipated that as soon as the Baltic is open there will be a considerable rise.

Chemical Works.—The chemical works at Seaham Harbour are now being rapidly put in order. They have been acquired by a limited company, of which the leading partners are principals in the firm owning Newburn Steel Works.

NEWCASTLE, 4th April, 1888.

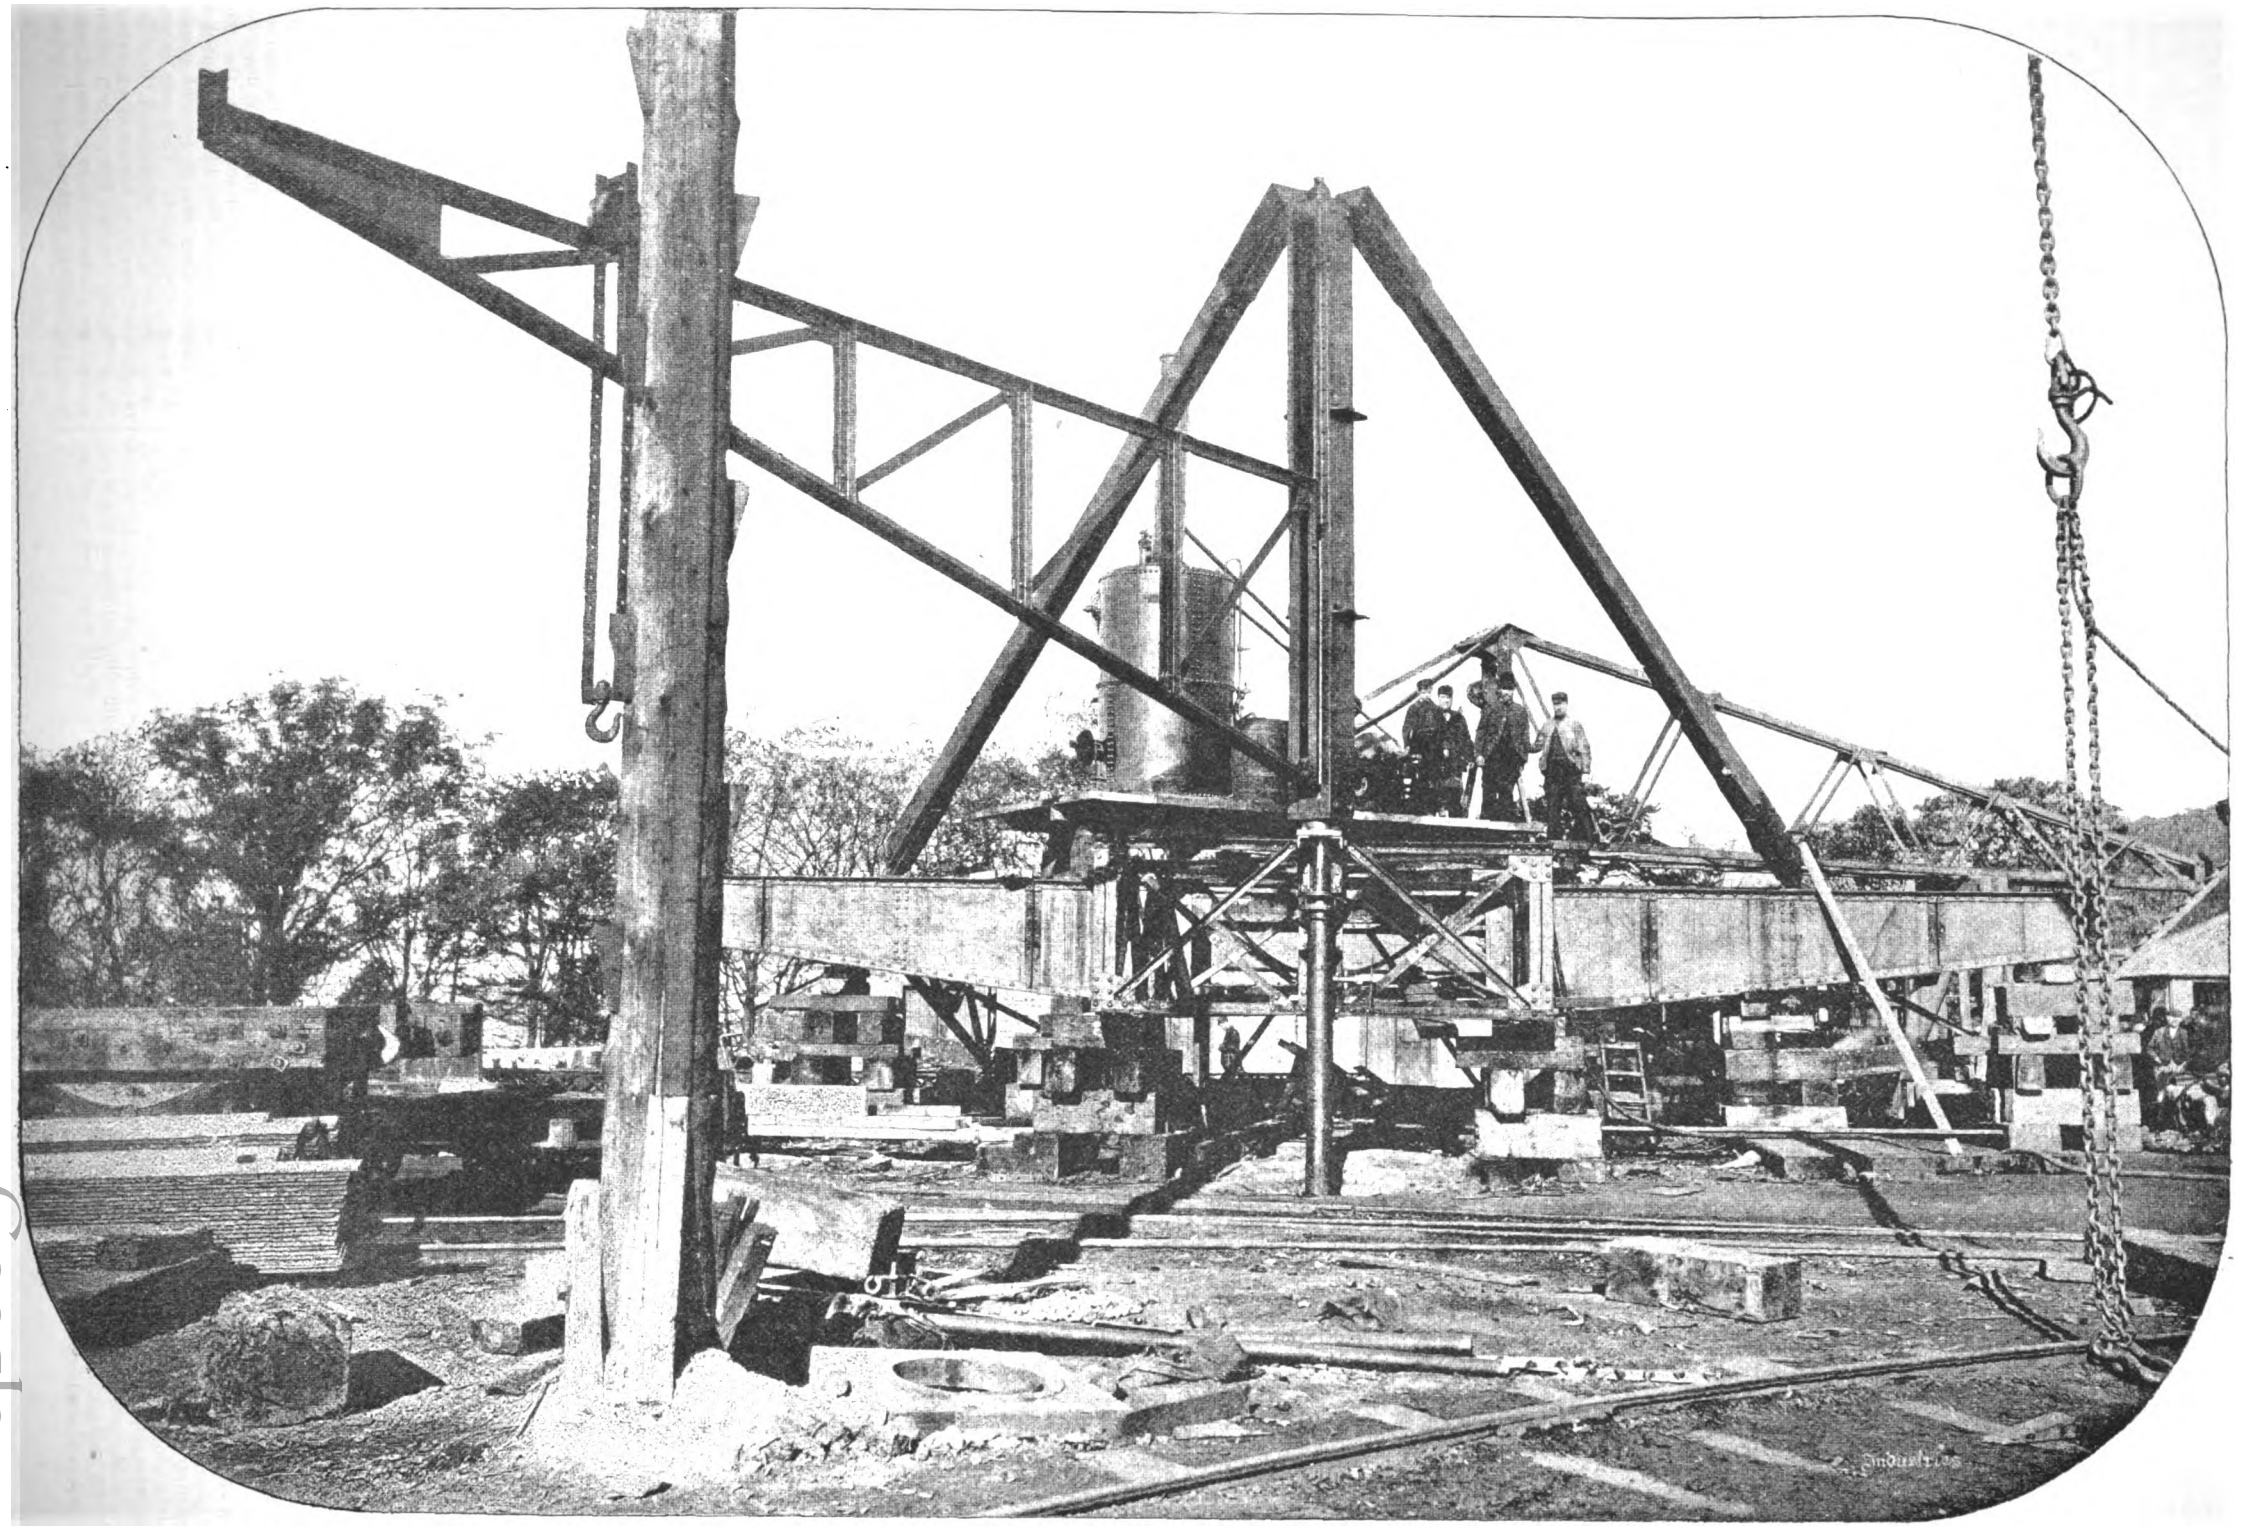
Shipbuilding. — The acquisition of new orders by Tyne shipbuilders is now a comparatively rare occurrence, and there can be no doubt of the fact that since the opening of the year the demand for vessels has been greatly reduced. As the number of orders placed during December, however, was very large, there is assured activity for most of the building yards during the present year, and, in some cases, the briskness is likely to be continued for a much longer period. During March Messrs. Palmer launched a couple of vessels, and have since put down keels in the berths vacated. The firm have now ten vessels, representing in the aggregate a carrying capacity of about 40,000 tons, in course of construction, and the frame turners are still busy with the frames for other vessels to be laid down. Among other orders now in hand Messrs. Richardson have a vessel of first class type to build for the China trade. Messrs. Armstrong, Mitchell, & Co. are filling up their berths, most of which were vacant at the close of last year, with keels for vessels of a large class, and they are now taking on hands in several departments. It has been announced that the armour plated ship "Victoria" will be removed from the Tyne to Chatham in the course of a few days. The vessel was launched from Messrs. Armstrong, Mitchell, and Co.'s Elswick yard about a year ago. There is nothing of a special nature to note in reference to the other yards on the river; but all the repairing establishments are, it may be stated, well provided with work.

Engineering.—The activity at Messrs. Palmer's Engine Works, Jarrow, is quite on a par with the state of business in their shipbuilding department. There are more than twenty sets of engines, several of them of exceptional power, now in progress, and the designs for others are being prepared. The other marine engine works in the district continue extremely busy, and such establishments as are engaged in the production of steam winches, steering gear, &c., are also very fully employed. In locomotive shops dulness is still the feature, and the slackness at the Elswick Ordnance Works is becoming more pronounced. A large number of hands were discharged last week, and it is understood that a good many others will be paid off within the next few days.

BELFAST, 4th April, 1888.

General Trade.—Shipbuilding and engineering firms still continue to be well employed, both on new work and repairs. Foundries and machine shops are better employed than they have been for some time, and in one or two cases have large overhaul jobs and repairs in hand. Manufacturers of felt for roofing and sheathing ships are very busy, chiefly with an export trade. The state of the woollen trade still continues favourable, and the factories lately started have received a fair supply of orders.

Linen Trade.—Owing to the Easter holidays the amount of trade has somewhat diminished, but prices still continue firm. The various spinnings of yarns have been rather quiet, but the prices remain good. Cloths and brown goods have had an improved demand, with an occasional advance in price. The rapidly increasing industries of shirt, pinafore, collar and cuff, and handkerchief making are in a very prosperous condition, and employ a large and increasing number of hands. Some new factories have been started for the manufacture of hem-stitched cotton handkerchiefs, and are doing a large trade. Much dissatisfaction is felt at the high rates charged by the railway companies, whereby manufacturers in inland towns are placed at a very great disadvantage, both coals and manufactured goods having to be conveyed by road or canal, thus causing serious delays.



Exhibitions.—Much interest is being taken in the Glasgow Exhibition, and many of the leading firms have obtained space for their exhibits. Messrs. G. & J. Burns have arranged for a special service of steamers at low rates from Belfast to Glasgow during the Exhibition. The Irish Exhibition to be opened in London on the 4th June is not attracting so much attention as it deserves.

Launch of a Caisson.—On the 29th ult. Messrs. Workman, Clark, & Co., Limited, launched the second of two caissons they are at present constructing for Her Majesty's Government. They are intended for use in connection with the extension of the Admiralty works at Queenstown, one being for use at a graving dock, the other for a floating basin. The caisson which was launched about four weeks ago is in a forward condition, and will leave the builders' works in a few weeks.

Advertisements intended for insertion in the current week's issue must reach the Manchester Offices not later than first mail delivery on Thursday morning. Scale of charges for displayed advertisements on cover and inside pages will be forwarded on application. Orders for single advertisements must be accompanied by payment in order to insure insertion, the charge for which is 2s. 6d. for the first four lines or under, and 6d. for each additional line; one inch and over at 7s. per inch; the line averages eight words. While all practical regularity in the insertion of serial advertisements will be observed, it can only be absolutely guaranteed in the case of those ordered to appear weekly.

All accounts are payable to the Publisher, JAMES F. BUTTERWORTH, *70, Market-Street, Manchester. Cheques should be crossed Manchester and Liverpool District Bank, King-street Branch, Manchester. Post Office Orders to be made payable at Manchester.*

FRIDAY, 6TH APRIL, 1888.

FORCED DRAUGHT.

AMONG the useful results of the recent meeting of Naval Architects, not the least valuable is the clearing away of the doubts and uncertainty which has hitherto enveloped the question of forced draught. So long as it remained a subject of controversy, the system could not recommend itself for general adoption. Engineers, said Mr. Fothergill, hesitate, for want of reliable data gained from actual experience, to accept the doctrines propounded in the numerous papers that have been written on the subject, and shipowners will not move without substantial evidence of a commercial gain. The want here suggested, the authors of the two papers read on the evening of the 23rd ult. have sought to supply. In collecting evidence for this purpose, the mercantile marine afforded a field for inquiry in one case, and in the other the examples were taken from among the different conditions prevailing in the Royal Navy. Thus we have a complete and an authoritative statement of observed facts, sufficient, it may be believed, to produce conviction in the minds of all practical men. Mr. Fothergill's paper treats of the subject of forced draught from the commercial point of view, and shows that in every case which has fallen under his notice, the adoption of the system has resulted in a very considerable gain. Incidentally he testifies also to the absence of destructive effects upon the boiler. Mr. Soper makes this matter the principal topic of his paper, and arrives at the same conclusion respecting the influence of forced draught upon the life of the boiler. This agreement is important; for the draught, which is represented by some ¾in. on the water gauge in merchant vessels, rises to 2in. on board a ship of war. Not less significant of the fuller knowledge we now possess, is the perfect accord which was manifested amongst the large audience of members and visitors present. There was but one opinion, and that was wholly in favour of the system under consideration. Bearing in mind the character of this audience, composed of marine engineers, shipbuilders and shipowners, we are led to believe that forced draught is no longer regarded as a project which must be experimentally investigated, but as an accomplished fact, ready for adoption under all circumstances.

The high importance of having set at rest this warmly controverted question, or, at least, of having led a large representative body like that assembled in the hall of the Society of Arts to a unanimous decision concerning it, will impress itself upon every practical mind. The advantages of supplying air under pressure to marine boilers are many and great. It leads not only to a notable saving of fuel, but to a large reduction of boiler heating surface, whereby space is gained for cargo, and dead weight is lessened. A striking example of this is to be found in the Atlantic passenger steamer "Celtic," of the White Star Line, whose boilers, after the application of forced draught, were reduced from ten to eight in number. This means, besides economy in other directions, a considerable addition to her carrying power. Another incidental advantage of no small importance, inasmuch as it affects the comfort and health of the stokers, is the reduction of temperature in the stoke holds, and the ventilation afforded. It was mentioned in the course of the discussion, that competition among stokers for appointments to ships provided with forced draught is exceedingly keen. All this is sufficiently obvious, and it was generally admitted. But there was thought to be at least one serious counterbalancing evil. The high temperatures consequent on forced draught were commonly believed—on what evidence it does not plainly appear—to be very destructive to the boiler plates. Had this apprehension proved well grounded, the system would have stood condemned for general application, though even in that case it might be of good service under conditions in which, as in the Navy, it is often of paramount importance to obtain the greatest possible power from the engines. But the results of experiments, and the constantly accumulating evidence afforded by actual experience, are opposed to the destructive theory. Much of this evidence was adduced and brought to a point at the meeting of the Institute of Naval Architects, and the result of the discussion must remove all doubts on the subject. The impression which must have been taken away from that meeting was that a great impulse has been given to the system by having brought the problem of forced draught within the range of definite and certain knowledge.

So far as the mercantile marine is concerned, the evidence in favour of the durability of the boilers under forced draught has all the conclusiveness of a demonstration, for not only has Mr. Fothergill given us, in minute details, the results of actual practice in numerous instances extending over considerable periods of time, but his figures throw us back upon old experience. The pressures with which he deals, and which seem to be those commonly used in the merchant service, do not exceed ¾in. water gauge. Now, a moderately tall chimney will give a water gauge pressure of fully ⅝in. Within these limits thousands of land boilers have been for many years worked under forced draught; and as no bad effects have been produced in these cases, it is hard to understand how any can occur to marine boilers whose fires are blown by a fan which produces no greater pressure than is represented by the draught of a large factory chimney. Shipowners may therefore avail themselves of a ¾in. blast in the certainty of suffering no injury from rapidly burned plates. Judging from the tone of the meeting, we are not likely to hear more of this objection. But the practice followed in the Royal Navy carries us much further; and if it be true that no injury is done by a 2in. blast—and Mr. Soper and others boldly affirm that none is done—there is nothing to fear from the adoption of forced draught to even a larger extent than that used by Mr. Fothergill. Evidently the next great step in marine engineering is the general adoption of a forced draught system, and it may be that in a few years we shall have no more of ¾in. water gauges, but rather of 1½in. to 2in. for merchant vessels. With such a blast, another boiler might have been removed from the "Celtic." This development, while adding considerably to the carrying powers of our cargo vessels, will benefit largely the marine engineering trades. The conditions of success are now pretty well known. As usually happens with new systems, the first attempt to apply forced draught frequently ended in failure. But these failures, as one of the speakers who took part in the discussion on Mr. Fothergill's paper showed, were for the most part attributable to a want of earnestness on the part of those who made a

Digitized by Google

trial of the system. Whenever it has been taken up with a determination to make the best of it, success has been achieved. Two notable instances are afforded by the "Ohio" and "Celtic," in which the first attempts proved utter failures. But the experiment was persisted in, and the final results were in the highest degree satisfactory. Thanks to a few shipowners of this kind, the engineer now finds himself in a position where he has to deal only with known facts and conditions. The cause of the hesitation alluded to by Mr. Fothergill having now been removed, we may reasonably expect that our leading marine engineering firms will face the question boldly, and that shipowners, convinced of the commercial gain to be acquired, will hasten on the improvement which we have described as the next great step in marine engineering.

THE COTTON TRADE.

Within the past few months public confidence in the shares of cotton spinning and weaving companies has, with the general realisation of successive profits, become more restored, and shares have consequently received more legitimate attention than for many years past. This has had the result of raising prices all round to a slight extent; and where buyers had the market practically at their command some nine or ten months ago, holders in paying concerns are now, almost without exception, above par with their demands. Only a few weeks ago shares in cotton companies had reached the highest point for many years; but since then, owing to the uncertainty and fluctuations characteristic of the yarn and cotton markets, a slight relapse has set in, and quotations are from 1s. to 2s. 6d. lower. In the share markets much difference of opinion exists, as might naturally be expected, in regard to the probable position of holders in the immediate future. If cotton rises in price, if yarn becomes more easily obtainable, or if the consumption does not increase, then there must necessarily be a decline in quotations; but, on the other hand, if the change in these respects be to the advantage of the spinner, a marked advance is sure to be the result. In the working of mills and factories under existing conditions of trade—that is, with modern machinery and good management, there is sufficient room to realise a profitable margin. Mills engaged in medium fine productions are specially favoured at present in this respect, next to which is the medium trade, while the fine trade comes in last to share this advantage.

Out of the cotton trade, industrial companies are generally looked upon as a source of investment, and when one profitable result has been declared the shares rise to a value which reduces the dividend or yield to the next buyer to about five or six per cent. Speculators only tamper with them to an extremely limited extent, as the business being of a comparatively non-speculative character, their tactics can do little to affect their position in the open market. In cotton spinning and weaving companies' shares, however, there is rapidly becoming a change from this rule, which is being brought about by the uncertainty and variation in the working results from quarter to quarter. Many companies have of late declared large profits at one stock taking, and losses at the next, while old concerns have paid dividends, and new and modern ones report adverse balances. Cotton also is subject to rapid variations in price, so that taking all these matters into consideration, cotton shares are looked upon as having a more speculative character than some investments.

In considering the position of cotton concerns and their numerous balance sheets, we may find that they can be divided into three different classes: (1) Those having old or over valued machinery at work; (2) those that endeavour to pay a fair and uniform dividend, and place the balance of profits to a reserve fund; and (3) those that disburse among the shareholders every farthing of profit as soon as it is realised. The shares of the companies which come under the first head are, almost without exception, of little use at any price to either speculators or investors. For example, what advantage is there to be gained in purchasing shares with say £4 out of £5 paid up, at a discount of perhaps 50s. or 60s., when there is a large adverse balance existing, and no prospect of it being cleared off? It is in those companies described under the second head that intending investors should place their capital, as they have there some guarantee of a return, and a prospect of a small dividend, even should trade become so bad that a profit could not be made. It will, however, be found that in examining the balance sheets of such companies from their first issue, that they have never failed to render the working operations profitable through every quarter, so that while profits may be expected, it is safe to assume that they will (unless by accident) be at all times able to maintain their position. With regard to the third class, they should be avoided by mere investors, as the results at each quarter vary considerably, and cause the shares to have a fluctuating value.

The position of producers, we are led to believe from present appearances, will at least continue as good as it now is for several months yet to come, and therefore we look upon the present as a favourable time for investment as regards the shares of the better companies. From information which we have reason to consider reliable, the companies named in the following list are at present doing good business, and are likely to show profitable results at the time of next stock taking. We understand that ring spinning business is doing exceptionally well, and that this will continue for some time, as it is in the hands of only a few concerns, who are becoming desirous of keeping their trading results from public view. They are therefore considering the advisability of discontinuing the publication of balance sheets, and if this system is generally adopted it may exert a favourable influence on their future results.

THE REGISTRATION OF ARCHITECTS, ENGINEERS, AND SURVEYORS.

We understand that the Bill which has been introduced into Parliament for the Registration of Architects, Engineers, and Surveyors is put down for its second reading on the 12th inst. It has received the support of a considerable number of provincial architectural societies, but is being opposed by the Royal Institute of British Architects and the Institution of Civil Engineers, and the Council of this latter body has prepared a statement of their objections to it, a few of which we will briefly mention. The most obvious objection is, that although the title of the Bill—which is Architects' Registration Bill—seems to imply that it only affects the profession of architects, it really includes all the various departments of engineering, which have little in common with architecture, as is proved by the fact that each of these professions has its own distinct chartered institution. As we mentioned, however, in our previous article on this subject, the engineers and surveyors which the promoters had in view, seemed to include, not the men who carried out engineering works in the proper sense of the term, but only those who were usually associated with architects and builders in laying out roads, drains, &c. It seems to be very much the custom for men who have got a smattering of building and surveying knowledge, suddenly to develop into architects, civil engineers, and surveyors, and their only diplomas are the huge brass plates in front of their doors. No doubt this is an evil to be guarded against; but the proposed Bill is too pretentious, and, as we have said, includes every department of engineering. Now, architecture is a well defined department, and there should be no difficulty in laying down the conditions of admission to the profession. Surveying is almost equally well defined, and the qualifications for admission to a surveyors' institute could easily be made to include the elements of construction necessary in connection with building operations. There would, moreover, be no great difficulty in the same men qualifying in both these departments, and they might put themselves forth as architects and surveyors, especially in country districts; but the term civil engineer is too big to be tacked on in addition.

The Council of the Institution of Civil Engineers denies the statement in the preamble of the Bill, that it is expedient that persons requiring professional aid in architecture, civil engineering, or surveying, should be able to distinguish qualified from unqualified practitioners, and therefore it is necessary that all properly qualified persons should be registered, but on the contrary it is of opinion that the Bill, should it pass, will not only be of no public benefit, but would be absolutely disadvantageous not only to engineers as a body, but to the public at large. The Council mentions that the Institution of Civil Engineers has on its roll representatives of all branches of engineering except military engineering. The members and associate members number at the present moment over four thousand. There is no restriction as to numbers, and all persons of fitting age, who can produce adequate proof of their competency in the profession, are admitted, either at once to the class of "member" or to that of "associate member," according to their qualifications; and in the case of the latter, when they have attained to a well recognised standing in the profession, they are, after full consideration by the Council, transferred to the class of member. In addition to the members and associates, the Institution has attached to it a class of students who are or have been pupils of corporate members of the Institution. The Council states that the Institution has from the first exercised extreme care in ascertaining that persons admitted as members or associate members of the Institution are worthy of their respective positions, and the result has been that membership of the Institution is recognised as evidence of the competency of the practitioner. The Council is of opinion that the system has been tested by the experience of sixty years, and with results eminently satisfactory, both to the profession and to the public. It is during this period of sixty years that all the great works have been executed and the improvements in mechanical science attained by which the present age will ever be distinguished, and in which the profession of civil engineering has been raised to its present high position, and the Council ventures to think that the House of Commons will hesitate before interfering with a system so well established, and found to be effective and of approved sufficiency.

BRITISH AND FOREIGN SHIPBUILDING.

It has become apparently a recognised necessity of the times that if England is to secure the work of foreign countries, she must go to those countries and establish in them factories in which the work can be carried on. The latest development of this system is witnessed in the new shipbuilding company that has been formed, under the chairmanship of the Marquis of Hartington, and with Lord Brassey and Mr. Nordenfelt on the Board of Control, in Barrow, with an auxiliary establishment in Spain. The latter departure has been induced by the fact that the Spanish Government are, as we have already informed our readers, about to undertake the re-construction of their navy; and as the movement is not confined to the Barrow Company, but is equally followed by the well known Palmer Shipbuilding and Iron Company, at Jarrow-on-the-Tyne, it is interesting, from an economic and business point of view, to consider how far it is likely to be carried, and what are likely to be its ultimate effects on British industry.

No one can blame the ministers of foreign States for desiring to establish within their own borders such industrial works as shall render them independent of external assistance, which may possibly fail them in their hour of greatest need. This requirement is now apparently a *sine quâ non* with all Continental States; and it is especially to be approved in reference to dockyards and arsenals, which give to a foreign power the entire command over their own vessels and munitions of war, since it may easily enough happen that hostilities may occur between the country that is dependent and the nation on which it depends. The question of founding such establishments within the limits of each European State is, therefore, one of national expediency, and is not necessarily, and may probably in nowise be one of profit and loss. It is in this view that the matter is usually regarded by Continental Governments. Whatever the ultimate cost may be, considerations of national safety and expediency prescribe the course that has been followed in Italy, and is now being followed in Spain. There are people who look upon such a movement as calculated to jeopardise the stability and prosperity of our great national industry of shipbuilding. They apprehend that by degrees these countries will not only supply the whole of their own wants, but will be competing with England in neutral markets, and deprive us of our shipbuilding trade. This would be a serious matter if the inference were true; but they must know very little of the primary requirements of the shipbuilding industry who fear for the future of England on this score. Our shipbuilding supremacy is the first condition of our shipbuilding prosperity. That alone will always keep us well to the front; but, apart from this, we have to a fuller extent than any other nation the other essentials of success in this industry, which are—(1) A widespread and profound knowledge of the art; (2) the command of cheap materials of construction; (3) the most highly skilled and experienced body of artisans in the world; (4) entire freedom from tariff duties, bounties, or any other artificial system, whereby freedom of trade is hampered and restrained. It is, no doubt, quite possible that these essential conditions may equally become the

Digitized by Google

possession of other countries. It does not, however, appear to be very likely at present. Spain could probably produce pig iron (and if pig iron, why not manufactured iron and steel?) as cheaply as our own country, if the same capacity, skill, and experience were brought to bear on the industry. One and a half million tons of pig iron are now annually produced in this country from Spanish ores. It might seem that this iron should be produced more cheaply in Spain itself, seeing that Spain has the ores on the spot; but yet only comparatively very small quantities of pig iron are produced in Spain. The reason is that in Spain the machinery does not exist for the production of iron and steel on a large scale. By machinery, we do not mean merely certain engines, tools, and appliances, but also a scientific knowledge of the process of manufacture and proper organisation. The Spanish workman is ill adapted for this class of work. The climate is against him, and he has not been accustomed, as the English workman has been, to mechanical labour at high pressure, and he has not the aptitude of the English workman for taking up and mastering the conditions of such employment. Nor is he disposed to work for much lower wages, although his services are usually worth very much less. An official report, recently issued by the United States Government on labour in Europe, states that at the Cadiz works of the Havana Line of Transatlantic mail steamers, where some one hundred men are employed, the hours of labour average 9½ per day, and the average rate of wages paid to general mechanics is $10, or 40s. per week; while blacksmiths' helpers only get 16s., and coppersmiths' helpers 18s. 9d. per week. In regard to other wages, they do not appear to be much under those ruling on the Clyde.

Foreign shipbuilding is, moreover, handicapped by duties and by bounties. Many examples of the onerous and irksome taxes that are levied, either directly or indirectly, upon the American shipping and shipbuilding interests, might be quoted. A very striking illustration of this is given in a report of the Special Commissioner of Revenue. Mr. S. C. Blanchard, of Yarmouth, Maine, stated that in a ship which he had built at a cost of 136,000 dols. (£28,000), 81,000 dols. (£17,000) was paid for materials, 30,000 dols. (£6,000) for labour, and 25,000 dols. (£5,000) to the State for taxes in various forms. It appears, then, that in this case 18 per cent. of the total cost of the ship went for meeting charges in restraint of industry. The case is similar in regard to other foreign countries. They have all tariffs which artificially enhance the cost of the materials required for shipbuilding, and so long as this continues their successful competition with free trade England is out of the question. It will be appropriate in this connection to consider how far the shipbuilding of England, for her own merchant marine, exceeds that of other countries, and how far, therefore, our great shipbuilding industry is fed by our own requirements. For this purpose we have compiled the above table, which shows the tonnage added to the registers of those countries that compete to any extent in the carrying trade of the world.

The great secret of England's supremacy in shipbuilding is contained in the fact that her own vast commerce necessitates the employment of a much larger merchant navy than that of any other country. The tonnage of vessels that have entered and cleared from the ports of the United Kingdom increased from 42,500,000 tons in 1872 to 64,250,000 tons in 1885. In the former year, the British tonnage—or rather the tonnage that entered and cleared from British ports—was 38 per cent. of the whole tonnage of the eleven chief countries of the world. In the latter year, it was 33 per cent. of such tonnage. If, therefore, Great Britain did not build a ton of shipping for any other country, she would still require to provide for 30 to 35 per cent. of practically the whole shipping trade of the world in meeting her own exceptional wants. We may therefore take it for granted that England is not to be dispossessed of her shipbuilding industry, even if a few of her great ship yards establish branches abroad. No doubt it would be more satisfactory if the works that are being, or are about to be, erected in other countries by English firms, could be kept here; but there appears to be no choice in this matter. It is not a question with the Governments of those countries whether the work can be better or more economically done at home. The ships must be so produced, cost what it may, and therefore in providing such works the great shipbuilders who have undertaken their construction are taking the only possible means of securing the contracts for themselves. The profits on those contracts will come to England; and although English labour will not be wholly employed, it may be taken for granted that every such establishment erected in a foreign country will employ a certain number of English artisans, at a considerable improvement on English rates of pay.

TENDERS for 5460 shares in Cassell & Co., Limited, were opened on the 26th ult. 13,568 shares in all were applied for, the average price of accepted tenders being £14.

Letters to the Editor.

THE MAGNETIC CIRCUIT OF DYNAMO MACHINES.

TO THE EDITOR OF "INDUSTRIES."

SIR,—Professors Ayrton and Perry have pointed out at the Physical Society that it is practically impossible to calculate the characteristic of a continuous current dynamo from the drawings. I am glad to be able to point out to them that the means of calculating the characteristic can be obtained from the papers on the subject by Mr. Kapp, and from the reports of the discussions on them. I enclose several curves showing the

calculated and actual volts and excitation. I may say that I have lately designed a complete series of dynamos of a new type, and have never had a preliminary test, and though numbers have been made with considerable modifications in the design, the volts at the calculated speed have always been within 2 per cent. of the mean. In many cases the dynamos have not been tested at the factory, but have been fitted on to the bed plate by the engine maker, the allowance made for the effect of the proximity of the engine and fly wheel being found correct. This has been done, not in a lecture room or study, but as part of the duties of a factory manager; and I need hardly point out that the saving of time and expense in being able to build machines without preliminary tests or alterations is immense. The methods I use are simply those given by Mr. Kapp, with the exception of the loss from leakage, in which case I use Professor Forbes' lemmas.

Yours, &c.,
Halifax, 26th March, 1888. HENRY W. RAVENSHAW.

EDISON TUBES IN MILAN.

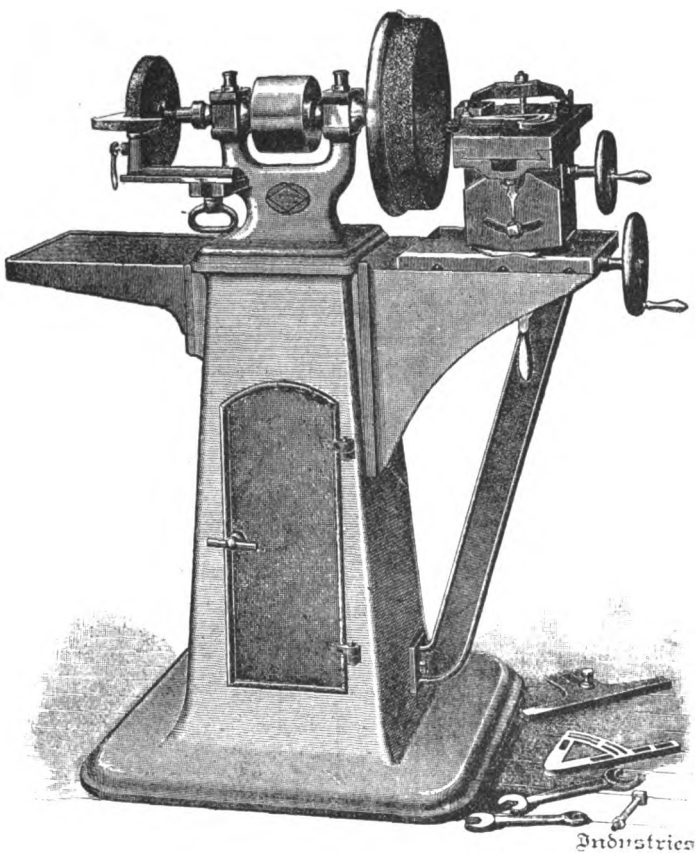
TO THE EDITOR OF "INDUSTRIES."

SIR,—Referring to the letter of your Milan correspondent in your issue of the 9th inst., no trouble whatever has been experienced with the Edison tubes in Milan, nor have there been any difficulties with leakage of the current. Since the first Edison tubes were laid in 1882 up to date, only fifteen or sixteen tubes out of the 2000 or more actually in use have been taken up, and but few of these had their insulation affected.

Yours, &c.,
Edison Station, Milan, J. W. LIEB.
31st March, 1888.

Legal Proceedings.

MORGAN & COMPANY v. WINDOVER & COMPANY.



The Court of Appeal gave judgment on Friday, the 23rd ult., in favour of the plaintiffs, thus confirming the judgment of Mr. Justice Kekewich. In 1876 a patent (No. 4216 of 1876) was granted to George Henry Morgan for "improvements in carriages." The action was for infringement of this patent. At the date of this patent there were two ways in which the carriage was supported—(1) By elliptic or bow springs; (2) by C springs. The object in either case is to effect easy motion, and to obviate sudden shocks. There are, however, distinctions between the two methods which require notice. First, as to the action. In the elliptic or closed spring, the action of the spring is vertical, whereas in the C spring there is a horizontal as well as a vertical action. Now, as to the mechanical differences between the construction of the two kinds of carriage. In the carriage which has elliptic springs, it is possible to obtain a full lock. Where C springs are used a half lock only is possible, because of the perch—the perch forming the connection between the back and front wheels. When elliptic springs are used, the carriage itself connects the back and front wheels.

The plaintiffs' case was that, before 1876, no carriage had been constructed with C springs fore and aft without a perch, and that the front spring gave a sensible longitudinal motion. The patentee claimed that he obtained by his invention the advantages of the C spring, dispensed with the perch, and thereby obtained a full lock. The defendants denied the validity of the patent, alleging prior specifications and prior users. The defendants nearly succeeded in one of the prior users set up by them in 1848; but the majority of the Court of Appeal (chiefly on account of the distance of time) would not rely on the memories of the witnesses, and looked on it as an abandoned experiment.

The real interest to inventors in this case centred in the point as to the amount of invention necessary to support letters patent. The objections to the patent took the following form: (*a*) That the plaintiffs' spring was a mechanical equivalent of an elliptic spring; (*b*) that the plaintiffs' spring produced no different effect from an elliptic spring in regard to the support or behaviour of the carriage; (*c*) that there was no novelty in the invention, or no subject matter for a patent, inasmuch as it consisted in using a known article for an analogous purpose to that for which the article was designed. In July last Mr. Justice Kekewich held that the invention had not been anticipated, and also that "the method of application required the exercise of the inventive faculties," and granted to the plaintiffs the injunction and other relief prayed for. The defendants appealed. With the exception of the one prior user referred to, the Court of Appeal were unanimous in their judgment. The judgment was delivered by Lord Justice Cotton, to the effect that the invention was admittedly useful, and that the one point to consider was whether the patent was valid. There was no proof of prior user before 1876 (except the abandoned experiment in 1848), therefore the invention was novel. What, then, asked Lord Justice Cotton, was the true meaning of Mr. Moulton's objection that there was no horizontal motion in the carriages patented by Morgan? If this was an attack on utility, utility has been distinctly proved. If, on the other hand, it was an attack on subject matter, the production of a carriage whereby the perch was got rid of and shocks were obviated, formed the proper subject matter of letters patent. There was horizontal motion, it may be slight, nevertheless

Digitized by Google

UNIVERSAL GRINDING MACHINE.

sufficient to lessen shocks. With regard to the objection of insufficiency of invention, that the springs were old, and admittedly had been used on the back wheels, the Court held that the selection of a proper spring, and the adaptation of it in a proper way, did constitute sufficient invention, especially bearing in mind that carriage builders had for many years been trying to obviate the difficulties. The validity of the patent was therefore upheld, and the appeal dismissed.—Sir Richard Webster, Attorney-General, Mr. Aston, Q.C., and Mr. Chadwyck Healey represented the plaintiffs; Mr. Moulton, Q.C., and Mr. John Cutler were for the defendants.

BOILER EXPLOSIONS IN AMERICA.

The *Locomotive*, published by the Hartford Steam Boiler Inspection and Insurance Company, Hartford, Connecticut, states that no less than 198 boiler explosions occurred in the United States during the year 1887, by which 264 persons lost their lives, and 388 were seriously injured; making a grand total of 652 persons killed or badly hurt. They are classified as follows:—

Saw mills and other wood working establishments	73
Locomotives	14
Steamships, tugs, and other steam vessels	14
Portable boilers, crane boilers, and agricultural engines	20
Mines, oil wells, and collieries	13
Paper mills, bleacheries, digesters, &c.	5
Rolling mills and iron works	15
Distilleries, breweries, dye works, sugar houses, and rendering works	9
Flour mills and grain elevators	7
Textile manufactories	1
Miscellaneous	27
Total	198

Nearly 37 per cent. of the whole number of explosions were, as usual, furnished by saw mill boilers. Portable boilers, crane boilers, and agricultural boilers came next, but their number forms little more than one-fourth of those occurring in saw mills. Rolling mills follow with fifteen explosions, while locomotives and steam vessels tie for the fourth place, the other classes supplying about the usual number of explosions. The number of explosions in the United States during the year 1886 was 185, killing 254 persons, and injuring 314; there is therefore a slight increase in the year 1887, both in the number of explosions and also of the killed and injured. The Americans are certainly far and away before us for frequency and fatality of boiler explosions. Our list for the year 1886-1887, of 24 boiler explosions, causing 37 deaths and 44 injuries, has a lean and beggarly look beside the fat and plethoric one given above. It is a list which can scarcely be viewed with feelings of complacency by American engineers, and it certainly should receive their careful and serious attention.

UNIVERSAL FACE AND ANGLE GRINDING MACHINE.

The above illustration, for which we are indebted to our comtemporary the *American Machinist*, represents a new universal face and angle grinding machine, recently introduced by the Diamond Machine Company, Providence, R.I. This machine is intended for the grinding of a large variety of work where only a small amount of metal has to be removed and a flat and true surface is required. It is claimed that this machine does the work of light planing and milling machines much quicker than the latter, besides giving a better surface to the work under operation. The work is secured either direct or by means of special devices to a slide rest, which is adjustable to any required angle in the vertical plane, and carries a pointer and graduated scale, to enable the operator to set or re-set the slide rest to a given angle for grinding bevel surfaces true and exactly alike. The slide rest is supported by a pivot on a graduated plate, so that it can be made to form any angle in the horizontal plane with the axis of the shaft on which the grinding wheels are fixed. One of the grinding wheels shown in our illustration is of an annular or cup shape, and has a diameter of 12 inches.

SHIPBUILDING NOTES.

A few days ago there was launched from the yard of the Sunderland Shipbuilding Company, Limited, South Docks, Sunderland, the steel screw steamer "Chanzy," built to the order of a firm at Caen, France. The dimensions of the steamer are: Length between perpendiculars, 190ft.; breadth, 30ft.; and depth of hold, 14ft. The vessel is classed 100 A1 at Lloyd's, under special survey, and has a long raised quarter deck, extending to the fore end of the boiler space; short hurricane house, in which there is accommodation for the captain and officers, and topgallant forecastle, with crew accommodation. Patent windlass, two steam winches, wheel and pinion steering gear amidships, and screw steering gear aft, are included in the deck outfit. The vessel has been specially designed to carry a large cargo upon a small net register tonnage, and will be employed in the coal trade between Wales and Caen, and has three large cargo hatches fitted with patent cleats. The main, quarter, and forecastle decks are of iron, and the hurricane house deck of wood. The engines—on the triple expansion system—are being fitted by the North-Eastern Marine Engineering Company, Limited, Sunderland, and have cylinders 16in., 26in., and 43in. in diameter, 30in. length of stroke. The boiler is of steel, and of 150lb. per square inch working pressure.

Two small steel screw steamers for passenger service in the Mediterranean were launched by Messrs. William Simons & Co., of Renfrew, on the 24th ult. The vessels are fitted with engines of 85 h.p., the boilers being constructed for a working pressure of 120lb.—On the same date, Messrs. Russell & Co., Port Glasgow, launched the "Victoria" steel screw steamer—298ft. long, 38ft. 5in broad; 1600 tons net register; carrying capacity, 3600 tons. The vessel has been built to the order of Mr. F. Woods, London, and the construction has been superintended by Mr. David Pollock, naval architect, Glasgow. The engines, which are to be of the triple expansion type, will be supplied by Messrs. James Howden & Co., Glasgow.

On Tuesday afternoon, the 27th ult., there was successfully launched from the yard of Messrs. William Doxford and Sons, Pallion, the new screw steamer "Julio," built for the Compania Bilbaina de Navegacion, Bilbao. The "Julio" is built of steel, her dimensions being: Length, 275ft.; width, 36ft.; depth of hold, 23½ft. The vessel is intended for the wine trade. Her engines have triple expansion cylinders, 20in., 33in., and 54in. diam., and 36in. stroke. The vessel will carry 2800 tons cargo on 19ft. draught, and is in every way fitted with the most modern arrangements for economical trading.

A twin screw steamer, the "Neptune," built from the model and plans and under the superintendence of Mr. William Glove, of Liverpool, for the Mersey Docks and Harbour Board, was launched on the 26th ult. from the yard of Messrs. R. & J. Evans & Co., Brunswick Dock. The vessel was then taken to the Sandon Graving Dock to receive the engines and machinery, made by Messrs. D. Rollo & Sons. The vessel is to act as a dock tug, and will also be fitted with a Merryweather fire engine, capable of throwing a jet of water 190ft. high at the rate of 750 gallons per minute.

On Monday, the 2nd inst., there was launched from the yard of the Fairfield Shipbuilding and Engineering Company, Glasgow, the "Lady Torfrida" screw steam yacht for Sir William Pearce, Bart., M.P. The new "Lady Torfrida" is larger than the former vessel of the same name. The tonnage yacht measurement is 735 tons. The length of the vessel is 216½ft., breadth 27ft., and the moulded depth 19ft. The engines, which are of the triple expansion type, are to indicate 1400 h.p. The yacht will be lighted throughout by electricity, and the appointments will be of the most luxurious description.

On the 28th ult. there was launched from the yard of Messrs. S. P. Austin & Son, Sunderland, the screw steamer "Orkla," built to the order of a Leith firm. The vessel has been constructed of Siemens-Martin steel, and is of the following dimensions: Length between perpendiculars, 282ft.; breadth, 38ft.; depth, 19ft. 3in. There is a full poop, long hurricane house to fore hatch, topgallant forecastle, iron masts, and cellular bottom for water ballast. The engines are of the triple expansion type, and are of 200 n.h.p.; they have been built by Mr. George Clark, of the Southwick Engine Works.

On the 28th ult. there was launched from the yard of Messrs. Jos. L. Thompson & Sons, North Sands Shipbuilding Yard, Sunderland, the steel steamer "Resolution," which has been built to the order of Messrs. Rowland and Marwood, of Whitby. The vessel is of the well-decked type; length between perpendiculars, 284ft.; breadth, 37ft. 10in.; depth, 20ft. 10in.; and has a dead weight capacity of 3050 tons on a light draught. The engines are given as 181 h.p., and are of the triple expansion type. They were built by Messrs. Thomas Richardson & Sons, of West Hartlepool.

On Tuesday morning, the 3rd inst., Messrs. Raylton, Dixon, & Co. launched from the Cleveland Dockyard, Middlesbrough, a fine steel screw steamer, named the "Guy Colin," which has been built to the order of G. E. Bowring, Esq., of London. Her dimensions are: Length, 300ft.; breadth, 38ft. 2in.; depth, 20ft. 6in.; having a dead weight capacity of about 3350 tons. The engines will be fitted by Messrs. Richardson & Sons, of Hartlepool.

Messrs. W. Richardson & Co., Newcastle, launched, on March 29th, a fine steamer, named the "Alfonso XII.," which is intended for the mail and passenger service between Spain and the Antilles. The vessel, which has stood on the stocks in a nearly completed state for four years, was purchased by the present owners a few months ago, and has since been greatly altered to suit their requirements. The vessel is 426ft. long, 47½ft. wide, and 36ft. deep, and has a carrying capacity of over 5000 tons. She will be elaborately fitted out, and is likely to take rank with the very finest ships afloat.

Messrs. Alexander Stephen & Sons launched last week from their yard at Linthouse, Glasgow, a steel screw steamer of 2500 tons carrying capacity. This vessel has been built to the order of Messrs. Maclay & MacIntyre, Glasgow. The engines are to be triple expansion, the cylinders being respectively 18in., 29in., and 46in. diam.

Reviews.

Dictionnaire d'Électricité et de Magnétisme. By Ernest Jacquez. Paris: Libraire C. Klincksieck.

This is the second edition of a work which originally appeared in 1883. We learn from the preface that over four hundred words have been added in order to bring the book up to the present date. The book is a dictionary of French terms used in connection with applied electricity and magnetism, and the German and English terms are also added. At the end of the volume is a German-French and an English-French dictionary of electrical

Digitized by Google

terms, by which addition the book is rendered useful not only to French, but also to German and English readers. The explanations given are generally clear and correct, but in many cases not sufficiently detailed; whilst in the historical portion of the work there is a certain tendency to give rather more than a due share of credit to the French scientists, whereas the work done by other nations is often omitted. Thus, for instance, we read in the chapter on thermopiles that the laws of thermo-electricity were discovered by Becquerel, whereas in reality the most important contributions to this science were made by Thomson and Tait. In the chapter on dynamo machines the credit of having established their theory is similarly given to Marcel Deprez, and not to the German and English physicists who have done the greater portion of this work. Practical electricians will be disappointed if they expect to find short descriptions of modern dynamos in this book. Under the title "dynamo-electrique," mention is made of the Siemens, Wheatstone, Gramme, and Wilde machines; but the names of Bürgin, Brush, Crompton, Weston, Edison, Hopkinson, &c., are conspicuous by their absence. The paragraph on electric transmission of energy is a long way behind the times, being mainly a general discourse on the experiments made by Marcel Deprez, and the old exploded theories that the ratio of speed between generator and motor is a measure of the efficiency, and that the efficiency is independent of the distance of transmission, are again set forth at great length. The paragraphs which deal with purely scientific matters, and especially those devoted to the absolute system of measurement, are, however, very well written; but it is evident that the author of this dictionary is more at home in the physical laboratory than in the workshop of a practical electrician.

The Theory and Practice of Electric Deposition. By Dr. G. Gore, F.R.S. New Edition. London: Charles & Co.

In this well known little book the student is guided by a strictly inductive exposition from the first principles of the subject to a familiar knowledge of all the practical details of the electrolytic art. It is at all times somewhat hard to decide on the best arrangement of an elementary text book; how far the strict sequence of the phenomena and their deductions are to be followed, and how much, and at what points, light from a more advanced stage is to be admitted. In the present work much care and thought have evidently been expended upon this point, the outcome of which is that the author divides his subject into three heads, viz.: (1) The facts observed in electrolysis; (2) The principles underlying these results; (3) Practical recipes and rules for use in the workshop. The first of these is divided into seven sub-headings on the different modes of deposition, viz.: by (1) One metal and one liquid; (2) Two metals and one liquid; (3) One metal and two liquids; (4) Two metals and two liquids; (5) By using any of the above, except the first, as a source of e.m.f. and connecting to a separate depositing liquid; (6) Same as above, but with some other source of e.m.f., and (7) Combinations of the foregoing. Seven conditions of deposition are also named under the second heading of "Principles." The above arrangement of the subject is quoted by the author as having been marked by much success in the lecture room, and this is apparently the chief reason advanced for its adoption in the present work. That it should be best to follow a strictly inductive progress in a class where experimental demonstration can be resorted to, and where the interest of pupils can be sustained by personal influence, we have no doubt whatever, but we are by no means so sure that the same course should be followed in a text book. By such a system the student is presented with a mass of phenomena occurring under certain conditions, and also with an equally voluminous list in which the results are negative. These he wades through and laboriously strives to fix upon his memory; but in all probability only succeeds in reducing them to a state of chaos in his mind. Here we certainly think it would have been better to introduce the electro-chemical law at the outset, together with the calorific principles involved in the decomposition of an electrolyte. From thence it would have been an easy step to the true conception of e.m.f., thus paving the way to a quantitative treatment in the electrical branch of the subject. Having once grasped the idea of the close alliance between, or we might almost say, the identity of e.m.f. and chemical tension, the student would experience a new interest in his study, and would also be equipped with a powerful mental tool wherewith to handle the somewhat complex questions arising in practical work. We do not wish by these remarks to detract in any way from the undeniable merits of the book, considered merely as a popular treatise on electrolysis. As a text book for students it might be improved; as a popular treatise it is highly commendable, both in clearness of style and thoroughness of detail, whilst the practical information contained will prove of great value to those engaged in electrolytic processes.

The Practical Engineer's Hand Book. By Walter Hutton. London: Crosby Lockwood & Co., 1887.

This volume is designed as a companion to the author's book, "The Works Manager's Hand Book," which we have already noticed, and the two works form a most valuable compendium of mechanical engineering knowledge, as they both contain a good synopsis of the chief departments of applied science, in simple language, and in a concise and condensed form, as well as the results of recent researches and experience in the various branches of engineering, a considerable quantity of which has not been published before, but collected for the author's use in the course of his own work. The whole has been exceedingly well arranged, and is certain to find a place in many drawing offices. The following synopsis of the contents of the volume now under consideration will give some idea of their range: Air, gas, and water; air motors, gas engines, and water motors; fuel, combustion, products of combustion; heating power and evaporative power of fuel, evaporation of water to steam; heat and heat energy; methods of burning liquid fuel and refuse fuels; evaporative effect of natural draught and forced draught in the furnaces of steam boilers; propulsion of modern steamships, with description of, and rules for, various propellers; evaporative performance of various kinds of modern steam boilers; boiler explosions, their causes, and the usual manner in which boilers explode; rules and practical data for the construction of modern locomotive, stationary, and marine engines and boilers; rules and practical data for triple expansion and quadruple expansion engines; strength and specific gravity of a variety of materials, collated from careful experimental data. Such a wide range of subjects might be supposed to necessitate very shallow treatment; but this is by no means the case, as each department is treated with a completeness which will be found to fully meet the wants of the majority of practical men. The part on boilers of different kinds is of considerable value, embodying, as it does, all recent experience, combined with a good outline of the principles involved, while that on the design of engines is about the best practical guide which we have yet seen. The only critical observation which we may offer is that in some cases the rules given are too numerous, and no sufficient opinion given as to which is to be preferred, and so the young engineer is apt to be confused. We have outgrown the ordinary pocket book crammed full of formulæ of all kinds, with no statement as to how they have been derived. On the other hand, the text books are beginning to develop in the direction of putting their results into practical shape, so that they may be used by engineers. Mr. Hutton's books are intermediate between the pocket books and the text books, and represents the tendency of their development in opposite directions—the one in the direction of more science, and the other in that of more practice. The ultimate form will thus be one which we have often indicated, and will contain sufficient science to show the general principles which underlie all cases, for which rational formulæ will be deducted, and from these, by the substitution of the contents representing current practice, empirical expressions will be obtained, which can be immediately applied.

Sewage Treatment: Purification and Utilisation. G. W. Slater. London: Whittaker & Co.

The sewage question is to science in this country what the Irish question is to politics, in the sense and result of begetting a good deal of barren controversy, and promoting active dissensions amongst a body of men holding perhaps identical views on a great number of cognate subjects. Whilst, however, chemists have been engaged in fighting the great "battle of the standards," the practical habit and sanitary instinct of the nation have accomplished very much in the establishment of effective house drainage, and have given us a very efficient system for the immediate disposal of the interesting and complex waste products, denominated sewage. But every sense of complacency we have in contemplating this partial solution of a great difficulty is dispelled when we confront ourselves with the major problem which survives, viz., How to dispose of the enormous volume of polluted water continually issuing, under this system, from our centres of population. This is the problem dealt with by Mr. Slater in the volume before us. At the outset, we may congratulate the author on the production of a very readable work, not a small merit in these days of dry technical literature. The author's method is the "natural" one. Having enlightened the readers as to the complex nature of sewage, *i.e.*, the multitudinous sources of the products which it may comprise, and as to the how, when, and where of its injuries to animal life, he gives an account of the cesspool system and its transition under the "evolving pressure" of increasing population to our now general system of water carriage. Having thus converted our tribe of tiny demons into the one stupendous giant, we are taken through the armoury of clumsy weapons with which science has equipped us for the combat; but the tour of inspection, we venture to predict, will be found eminently unsatisfactory. The London schemes and their authors, Sir J. Bazalgette and his chemist auxiliaries, are very inconsiderately dealt with. Treating of irrigation with raw sewage, the author points out the acknowledged defects of the system—choking of the soil, the non-removal of disease germs, and the liability to putrescence of vegetables grown under irrigation; admitting, however, that the evils may be minimised by periods of rest. In the chapter on filtration, Professor Frankland and Mr. Bailey Denton, and the schemes they have proposed, are somewhat sarcastically dealt with. In treating of Professor Robinson's proposed scheme (1884), the author falls into a vein of criticism which is quite out of place in a work of this character. In the opening of the chapter on precipitation, the author effectively disposes of the contention that this treatment, while it may clarify the sewage, does not purify the solution. Then follows a succinct account of the various methods which have been proposed and tried. The author's condemnation of lime we cannot indorse on the reasons given, viz., that it gives an alkaline effluent, and therefore favours decomposition. We ask, why not? If decomposable matter is present, why not attack it? And, again, the author's experience, we are sure, has not led him to conclude that atmospheric oxidation, our most powerful natural auxiliary, is most effective in presence of an acid, or, at least, absence of alkaline reaction. A due consideration of this factor would probably mitigate his condemnation. On the contrary, observation and experience shows that the best system of sewage treatment is a lime precipitation, but followed, whenever practicable, by irrigation with the effluent. Is this what the author means by the term "inverse irrigation" (page 107), which, he says, "is included in every properly managed precipitation process, and which gets rid of almost all the objections which can be raised against irrigation direct?" In the same chapter we also find denounced as a "capital mistake" the practice of building sheds over the precipitating tanks. From this we also dissent. The author gives as his reasons, amongst others, that "free contact with air and access of light assist us little in purifying the sewage;" and further, "if the tanks .... give off a bad smell it is a proof that the process is not being satisfactorily worked." To this we object (1) that a still atmosphere above the tanks is a most important auxiliary to precipitation; (2) the amount of possible purification by air and light *in* the tanks is a minimum; and (3) if a bad smell is given off, and is an element in the diagnosis of the working, it is as well to confine it for observation. In this reasoning we are supported by the experience of Mr. C. Jones, C.E., of Ealing, who has come to very definite conclusions upon this particular point.

In the chapter on "deodorising" which follows, various methods of further treatment of sewage effluents are discussed, including the permanganate process adopted by the Metropolitan Board. The author dismisses them as either ineffective or too costly, or both, as in the last mentioned case. "Destruction," the heading of the following chapter, is very cursorily noticed. The disposal of "dust bin" refuse is a very important complement to our sewage schemes, and the difficulty is very efficiently dealt with in the "destructor" system as worked at Ealing, Bournemouth, Southampton, and some twenty other towns in England. It is true that at Ealing the precipitation sludge is also put through the fire and so lost to agriculture excepting indirectly, and in so far as the organic elements are returned in the form of ultimate products of combustion. This is a shock to the earlier idealists no doubt, but to practical men it is purely a question of economy, and the result at Ealing is satisfactory. In the chapter on promiscuous methods—the adjective is not without a touch of sarcasm—we find such processes as distillation, freezing, and the earlier proposals for "electric" treatment. Two of these, in the light of recent advances, may come to have a new significance. Mr. Gargan, the inventor of the new system of evaporation now well known, we are informed, undertook to distil certain polluted water for the City of Chicago, at a cost of 6d. per 1000 gallons. Such a proposition gives a new aspect to the question before us.

The "electric" treatment of sewage has a mysterious ring about it. This vagueness will be removed when the details of two schemes, now fully known to the officials of the Patent Office, are published, viz., those of Mr. Webster and of Mr. Hermite. On the latter we have had some conversation with the inventor, and his method appears to be specifically electrolytic, the purifying agent being electrolytic oxygen. Presuming that water power will be available, the cost of the system will be that of the motor dynamos and electrodes. It would be premature to discuss the proposal; we can only say that the experimental evidence fully demonstrates the efficiency of the agent. The chapter on the "Detection of Sewage Pollution" is well written and full of useful directions for observation. The "common sense" criteria of purity proposed at the conclusion are still arbitrary, yet a

Digitized by Google

welcome relief from the strained standards of the Royal Commission of ancient history. They are (*a*) absence of colour and turbidity; (*b*) absence of alkaline reaction—this we should be inclined to qualify for the reasons already given; (c) no turbidity produced by sulphate of alumina, one grain to one pint; and finally (*d*) absence of a persisting froth on shaking. The concluding chapters on the treatment of sludge and on sewage manure need no special comment. The penultimate chapter on sewage patents is an imposing record in more senses perhaps than one. Out of the 454 processes, how many survive? In the last chapter the author reproduces the discussion on Dr. Tidy's paper of May 15th, 1886, before the Society of Arts. We have endeavoured to give a fair outline of the work, and in concluding our notice we give our *general* impression of the book, which is that it is suited to laymen, who will find it very interesting reading, rather than to specialists.

Gun Making in the United States. By Captain Rogers Birnie. Ordnance Department, United States Army.

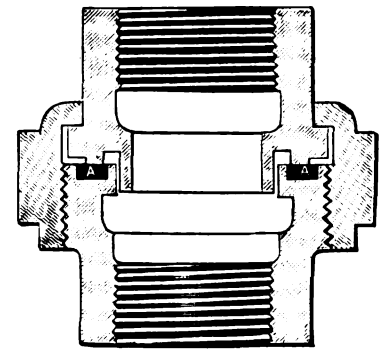
The above pamphlet is the reproduction of a lecture delivered at the close of last year before the Military Service Institution, and contains a capital summary of the gun question in the United States, gradually tracing events from the period of the cast iron guns of 1860 to the forged steel ordnance of to-day. Many things contributed to the slow progress made by the United States in the development of their artillery, nor was it till quite recently that decisive steps were taken to raise its efficiency. Eight years ago no steel gun had yet been constructed in that country, and the most powerful weapons in the States were converted cast iron guns with steel tubes; guns confessedly of third rate power, and even at the present moment the only ones available for coast defence. But in 1880 the Navy Bureau, being convinced of the necessity of new type guns, turned their attention to steel, and in 1883 a vote of Congress so strengethened the hands of the Ordnance Department, that it entered seriously into the construction of ordnance made from forged steel, and every encouragement was given to the home production of that metal.

Since 1883, this department has procured from American manufacturers some 200 tons of oil tempered and annealed gun steel forgings, which have been supplied principally by the Midvale Steel Company and the Cambria Iron and Steel Works. Of this material, a portion has been used for the manufacture of guns under 13 tons, and with the rest very important experiments have been carried out, with the object of elucidating the principles of gun construction. Amongst these the following may be noted: (1) Shrinkage and specimen tests of steel hoops, to determine qualities of metal best suited for purposes of gun construction, based on methods of treatment in manufacture; (2) construction of a compound cylinder, representing a full section through the reinforce (around chamber) of the 8in. breech loading steel gun; (3) frictional resistance to longitudinal separation of finished steel cylinders, shrunk one over the other, as in gun construction; (4) shrinkage and specimen tests of forged steel trunnion hoop, to determine qualities of metal throughout the forging; (5) examination of the strains produced by oil treatment, and the effect of, after annealing, in removing injurious strains from the forgings. Captain Birnie enters with some detail into a consideration of these and other preliminary experiments, and also sets forth the theoretical formula made use of in America. In an appendix, the subject of initial tensions is treated from a mathematical point of view.

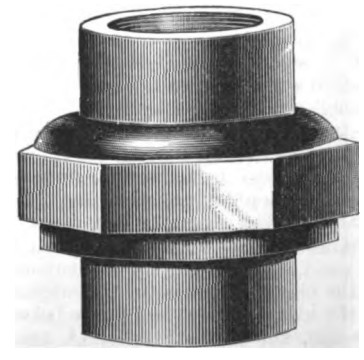
In June, 1886, the Ordnance Department completed their largest gun, the 8in. breech loader of 13½ tons, for which the heavier forgings were supplied by the Whitworth Company. Its projectile weighs 300lb., and its powder charge is 113lb., giving a muzzle velocity of 1852ft., and a muzzle energy of 7133ft.-tons. The pressure is 16 tons. The construction of this gun somewhat resembles that of our 8in. breech loader, Mark III. or IV., but differs entirely from the latest design approved here for this calibre. It consists of a tube with a jacket shrunk over it, which extends to the trunnions. Over the jacket are two layers of hoops, those of each layer breaking joint; there is a trunnion ring, in rear of which the second layer terminates, and in front of the latter the tube is hooped to the muzzle with a second strengthening layer of hoops, extending for 29½in. in front of the jacket. The interrupted screw breech mechanism is adopted for this and all other new type guns. Commencing somewhat earlier, the Navy Yard has accomplished more than the Ordnance Department, and since 1883 have turned out twenty-one 6in. guns, eight 8in. guns, and two 10in. guns. In their main features the Navy and Army steel guns are alike, the most important difference in construction being that in the Navy guns the trunnion hoops are made of oiled, tempered, and annealed castings, and are screwed on cold; while in the others these hoops are forged, and put on by shrinkage.

In addition to the forged steel ordnance, it is proposed to try cast steel, and Captain Birnie argues out very fairly that, even if this system answers for medium calibres, the day is distant when they may hope to manufacture in America heavy ordnance in this way. However that may be, the Navy Department were granted the money last year to purchase three cast steel 6in. guns—one to be of Bessemer steel, one of open hearth (Martin-Siemens), and one of crucible steel. No bid was made to supply the last; but the Pittsburg Steel Casting Company have contracted for the first, and the Standard Steel Casting Company the second.

The main features of the two specifications are as follow:—Casting rough bored and turned Bessemer steel: Cost, $3,300; elastic limit, 40,000lb.; tensile limit, 80,000lb.; ultimate elongation, 7 per cent.; reduction of area, 7 per cent.; weight of finished gun, 11,000lb.; length of finished gun, 193·53in. Casting rough bored and turned open hearth steel: Cost, $5,300; elastic limit, 30,000lb.; tensile limit, 70,000lb.; ultimate elongation, 10 per cent.; reduction of area, 5 per cent.; weight of finished gun, 15,000lb.; length of finished gun, 193·53in. Casting rough bored and turned forging for 7in. steel howitzer (from Cambria Company): Elastic limit, 47,250lb.; tensile limit, 92,750lb.; ultimate elongation, 21·1 per cent.; reduction of area, 29 per cent. The forging is added for purpose of comparison with the castings, which would appear to be inferior in physical qualities.



Many interesting features of the pamphlet we have not even touched upon, and we can confidently recommend its perusal to our steel makers as a précis of gun making in the United States.



A Text Book of Paper Making. By C. F. Cross and E. J. Bevan. London and New York: E. & F. N. Spon. 1888.

We are glad to see that Messrs. Cross and Bevan have found time to write such a valuable contribution to our knowledge of paper making as the volume now before us. The scientific details of this industry require some one with more than mere technical knowledge to write a satisfactory account of the nature of cellulose, and the different operations required before the crude materials are converted into paper. The chemical and botanical attainments of the authors, and their previous scientific work, have enabled them to produce a text book which may be taken as a model of what an industrial text book should be. In their preface they state that their belief in the importance of a thorough scientific training for paper makers has dictated the style and purpose of the book, and we hope that all engaged in this industry will feel the truth of this statement. On reading the several chapters we are convinced that the majority of those now engaged in paper making will fail to follow the first chapter, which is devoted to a consideration of the chemical properties of typical members of the cellulose group, with reference to their natural history. It is well for the manufacturer to find thus early in the work his own want of knowledge of the fundamental changes, and the nature of the material employed in the work on which he is engaged, if only to show him the value of the work which scientific men from time to time have done towards perfecting and simplifying many of our industries. Chapter V., on the processes for isolating cellulose from plant substances, gives a very complete *résumé* of the various methods for the resolution of pecto- and ligno-celluloses by aqueous alkalies, alkaline sulphides, water, neutral sulphites, acids, and bisulphites. Pictet's method for disintegrating wood by means of sulphurous acid, and Francke's and Graham's processes in which the hydrolysis effected by the sulphurous acid is supplemented by combining the products with bisulphites, are discussed in this chapter. The different special treatment of various fibres, and the boiling processes employed with rags, esparto, and straw form the subject matter of the next chapter, and it is illustrated by figures of the plant employed. The important subject of bleaching is dealt with separately in a short chapter, and in it we have given a brief account of the new process for electrolytic bleaching, which has been recently developed by M. Hermite. This method has already been alluded to in this journal, and the authors having devoted some time to an investigation of its merits, seem very confident that the process will be found both a convenient and economic one. Bleaching effected by the use of the electrolysed magnesium chloride solution used is much more rapid than by the older processes, and the loss of weight which the substances undergo is less, for equal degrees of whiteness obtained. It is an inexplicable, but well confirmed, fact that such an electrolysed solution has a greater bleaching efficiency as measured by arsenious acid, that solutions of bleaching powder in the proportion of five to three; and from the trials which have already been made of this method, it appears that the bleaching of paper pulp can be effected at nearly one half the cost of bleaching powder. The beating of the bleached pulp is next described, and details of new forms of beaters, lately introduced into this country by Messrs. G. & W. Bertram, and of the beater devised by Cooke & Hibbert, are given. The next three chapters are devoted to a description of the methods employed for the mechanical processes of loading, sizing, colouring, calendering, cutting, and finishing, and to a discussion of paper machines and details of the manufacture of hand made paper. The "Fourdrinier" paper machine, with its modern improvements, is carefully described and illustrated, and the newer forms of self cleaning steamers and pulp savers also receive attention. Chapter XII. is an important one, and deals with the recovering of caustic soda and the methods employed for causticising the carbonate of soda; and in an addenda at the end of the volume a description of the Yaryan process for evaporation, as carried out in some of the largest paper mills in the United States, and Messrs. Bremner, Mond, & Co.'s ferric oxide causticising process, is given. The subject of paper testing, and the chemical and microscopical analyses of the materials employed, are discussed in the concluding pages. The chemical identification of the fibres in any paper by means of aniline sulphate has been worked out by the authors themselves, and by its use very small quantities of straw or esparto pulp in a paper can be detected with certainty. The preparation of the Willesden goods by means of the cuprammonium solution, patented by Dr. C. R. Alder Wright, and notes on the choice of a suitable site for the erection of a paper mill in relation to the water supply, and the methods for the purification of water by the Porter-Clark process, and with the Stanhope purifier, conclude the volume. Statistics of the paper industry to the close of 1884, and a catalogue of the more important contributions to the literature of the subject, are also given in the hand book. The chapter on the treatment of wood, we understand from the preface, formed the subject of the prize essay of the Scottish Paper Makers' Association, given in connection with the Edinburgh Forestry Exhibition in 1884. We cannot conclude without strongly recommending this work to all those interested in the subject, and congratulate the authors on the production of such a useful text book.

THE "LANCASTER" PIPE UNION.

The accompanying illustrations show a neat form of socket or union, invented by Messrs. Pancoast & Maule, Philadelphia, United States, for connecting pipes, which is intended to take the place of the flange and socket connection now in use. The sectional view shows the arrangement of the different parts, A A being a ring of non-corrosive metal. The whole of it is made of malleable iron except the ring A A. The advantages claimed are, that the metal packing lasts a long time—as it will not blow out or become oxidised—and that it is simpler than

the connections now in use, and obviates the use of rubber or leather packing. The chief feature of this union is its low price as compared with other connections. We understand that the metal packing will, for all practical purposes, resist the influences of steam, water, gas, acids, oil, ammonia, coal and natural gas, &c.; and the arrangement is therefore likely, considering its low price, to prove useful in many industrial branches. Messrs. Lancaster & Tonge, Lancaster Works, Pendleton, Manchester, are the sole agents for this useful device.

BROUGH'S AUTOMATIC VALVES.

In the accompanying illustrations, Fig. 1 represents a combined automatic drain and escape valve for steam engine cylinders; while Figs. 2, 3, and 4 show a combined automatic and ordinary water gauge fitting for steam boilers. Both these apparatus have been designed by Mr. Robert Brough, Sunderland. The combined automatic drain and escape valve (Fig. 1) is intended to reduce the danger arising out of the accumulation of water in cylinders, which causes occasionally the breaking of cylinders, cylinder covers, or the bending of piston rods. The valve may be fitted to the cylinders of marine, stationary, or locomotive engines. A A, in Fig 1, are two valve boxes enclosing the valve B and a piston C connected to it. The ends D D of the valve boxes may be attached to the cylinders in the ordinary manner. Both valve boxes are connected by means of a pipe E, into any part of which a hollow plug cock F is fitted. One side of F is in communication with the boiler by means of the tube G, while the other side is open. The area of the piston being greater than that of the valve, the pressure of the steam keeps the latter shut until the pressure caused by the compression of the steam or condensed water in the cylinder becomes excessive, when the valve B is opened and the waste discharged through the pipe H. If it be required to blow through the cock F is turned into such a position as to cut off the pipe G from the pipe E, and to establish a communication between E and the atmosphere, when the valve B will open and remain so until F is turned back to its former position. J are handles fitted with square ends engaging the piston C, and provided with valve seatings L, and passing through stuffing boxes, so that leakage is practically prevented. By means of J the valve B may be turned if it should become leaky.

Figs. 2, 3, and 4 represent a combined automatic and ordinary water gauge valve. This valve is intended for automatically closing the communication between the boiler and gauge glass in case of the latter breaking, thereby preventing the danger to the boiler attendant due to scalding, or damage to the boiler through collapsed furnaces. The water passes from the boiler through N N and the valve O into the gauge glass. Fig. 4, which is a section along the line A B (Fig. 3), shows valve O in section. The valve O, the piston P, and the cam box K are cast in

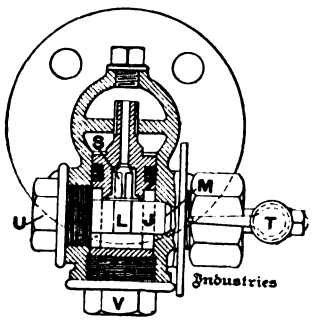

Fig. 4

one piece, the valve O having a perforation, while the piston P is provided with a valve S, shown in Fig. 4. The water passing through N gets through the perforation in O to the back of the piston P, thereby keeping it in equilibrium. As soon as the glass breaks the pressure on the top of P is relieved and the valve O closes, thereby preventing the water from escaping out of the boiler. The cam L and spindle J (see Figs. 2 and 4) are actuated by the handle T, which is provided with a pointer moving over an index plate W. According to the position of T the apparatus may be used either as an automatic one or an ordinary one. If the handle T be turned into the position marked "open" the cam L engages with the plate shown at the end of the cam box L, thereby keeping piston P and valve O open, even if the glass broke. The apparatus is then converted into an ordinary gauge glass. In the position marked "automatic" the cam L is disengaged from P and O, and does not influence either. If the handle be turned into the position marked "shut" the cam L closes the valve O, and also the auxiliary valve S. The plug nut V may then be removed for cleaning purposes. The only part which is liable to leakage is the cam spindle J, which is therefore provided with the valve seating M and a stuffing box (shown in Fig. 2), so that the leakage is rendered inconsiderable.

Engineering.—The royal factory of steam and other engines in Amsterdam is the largest private company in Holland. A short while ago a new loan of 300,000 guilders was raised by them, and the money will enable the directors to go in for big contracts with foreign Governments. The company commenced shipbuilding in 1882, and negotiations for new war vessels of a special type are now pending with Spain, Japan, and other countries.

STEEL SLEEPERS.*

In commencing, the author stated that his paper was not intended to be a complete *résumé* of the many questions involved in the use of iron permanent way; he desired simply to record a few brief notes on some points that have been brought before his notice during some experience gained in the manufacture and use of metal sleepers.

The introduction of iron for timber bearers to carry the rails was a by no means recent event. The late Mr. Greaves was, the writer believed, the first to design the cast iron pot sleeper that has since been employed in various forms, and in which the chair and sleeper were cast in one piece and maintained in gauge by transverse rods. The use of this and other similar forms brought out a fact that might have been anticipated at the outset, viz., that some nicety is essential in fitting and connecting up the line, and that, unless care is observed in making the castings, and adjusting the holes, a great deal of trouble is experienced in laying, especially in a foreign country, where mechanical appliances are not always at hand to remedy the manufacturer's defects. This is the point where timber shows up to such great advantage, and apart from other considerations in its favour, the writer believed it may generally be laid down as an axiom that, if suitable timber can be obtained at a reasonable price, it is not wise to employ either cast or wrought iron or steel in preference to it.

This conclusion would, of course, largely depend on the cost of steel, for the natural advantages of this material, and the perfection to which its manufacture has been brought, entitle it to a preference over wrought or cast iron, and its recent extraordinarily low price must not be regarded as a permanent standard for estimation. The author had not had an opportunity of making comparisons of cost over a series of years; but from abstracts of papers, written by German engineers in 1885, it appeared that one of these gentlemen estimated the life of a wooden sleeper, costing in the first instance 4s., at twelve years, and maintenance being excluded, the charge per annum is reckoned at 5·2d.; similarly, an iron sleeper (presumably wrought and not cast, though it is not stated which material is referred to) costing 8s., with a life of thirty years, works out to 4·9d. This proportion was said to be based on twenty years of practical experience; but the writer did not believe that sufficient time had yet elapsed, or that results from a sufficiently extended number of cases had been obtained, to definitely settle this disputed but very important question. So far as the writer was aware, Mr. F. W. Webb, of the London and North-Western Railway, was the first to design and make use of steel sleepers on anything like an extensive scale in this country. At that time about 32,174 sleepers were at work, which number, Mr. Webb informed the author in a recent letter, had now increased to 82,204, and with this extended experience, covering a period of about six and a half years, Mr. Webb still adhered to his original design, and saw no reason to alter it in any way. This sleeper was, of course, designed for the extremely heavy traffic of the London and North-Western Railway; it weighs 136lb., and is 9ft. long; two chairs and steel linings, to prevent the rail from injuring the sleeper, add 48lb. to this, making a total of 184lb. Brown paper soaked in tar is introduced between the chair and the packing, and the packing and the sleeper, to prevent moisture and sliding, the rail being kept in position by a wooden key in the ordinary way. The chairs are riveted to the sleeper. This method is very different from that adopted on light railways, and though Mr. Webb's system is evidently well designed and effective, it is certainly very expensive, and involves a good deal of labour at the manufacturer's yard. The section of the sleepers is 11in. at the base, narrowing to about 7in. at the rail bearing, and averaging about $\frac{5}{16}$in. thick. The rail is an 84lb. bull headed section, the lining on which it rests receiving the necessary cant of 1 in 20 at the time of stamping. Mr. Webb, in this design—which may be said to represent the latest development for heavy lines—has profited by the mistakes of the Continental engineers, who were the first to use metal sleepers for main lines. The failures which resulted twenty years ago when experimenting with wrought iron were due to using too light a section, and in consequence the 66lb. sleeper of that date was now enlarged to the 136lb. of the North-Western Railway. It appeared that, so far as Europe was concerned, the use of metal sleepers had progressed much more rapidly than in this country, and especially did this appear to be the case in Germany, where, in 1881, 8·1 per cent. of the total mileage was thus laid, and in 1885 this proportion had increased to 17 per cent. Similarly, South America, owing to the absence of timber, had largely adopted metal bearings, whilst in the United States and Canada they had been but slightly, if at all, employed; indeed, the writer was not acquainted with any instance in point in either of these last mentioned countries. In India, for the narrow gauge Government lines, steel appeared to be almost universally and by preference employed, and many thousands of these very excellently designed sleepers had of late years been sent out, and had formed a great source of business to the iron works in various parts of England, but chiefly in South Wales. There were, the author stated, two methods in vogue for the

*Abstract of a paper read before the Civil and Mechanical Engineers' Society, 18th January, 1888, by Mr. H. T. Munday, Assoc.M.Inst.C.E.

Digitized by Google

manufacture of steel sleepers; the one consisted of rolling a plate to the required section and form, and cutting it at once under the saw to the specified length; and the other of first rolling in flat plates and sawing, and then re-heating and impressing the necessary form upon a die under hydraulic pressure. The first process was undoubtedly the most expeditious and cheaper of the two, as the amount of handling (a serious item in pricing) is diminished as much as possible; for, after cutting and straightening, the only further operation involved was to punch the bolt holes and file the rough edges, the after process of dipping in solution, if necessary, being common to both. On the other hand, the pressed sleeper was undoubtedly a much more workmanlike production, and possessed an important feature in its favour, inasmuch as the ends could be closed up so as to form a complete trough or box on the under side; moreover, the centre of the sleeper could be deepened under the rail bearing and the ends spread out in a fish tail shape, neither of which advantages could be secured with the rolled trough, for though, of course, the ends could be closed, it could only be done by a separate and troublesome arrangement of riveting on a piece—a process which, though sometimes adopted before pressing became general, would certainly not be followed now. It being admitted, therefore, that, all things considered, a pressed sleeper was the most perfect job, it was obvious this form would be adopted by the Indian Government authorities, acting under the advice of Mr. Rendel. This sleeper was, when formed, 5ft. 6in. long by 4¾in. deep at the centre, and 7¾in. wide, gradually altering at the ends to about 4in. deep just beyond the rail, and splaying out to 13in. wide at the extremity. Originally the plate from which the sleeper is pressed is 5ft. 9in. long by 14in. wide by about $\frac{7}{16}$in. thick, with an increase of metal on the centre line 4in. wide, making a thickness of ⅝in. at this part. After the plate is re-heated in the furnace it is brought to the die and subjected to hydraulic pressure, which not only shaped the sleeper as described, but punched out two clips about 3in. by 2in. each, raised at an angle of nearly 30° above the surface of the sleeper, and between which the rail rested. The fastening was of the simplest. A steel key, tapering in all directions, was driven against the clip and rail flange, and was supposed in this position to hold the rail perfectly tight. When both keys were driven outside the flange, the gauge was obtained; but this could be very conveniently varied by driving one key inside and one outside, or both inside, and it could thus be narrowed or widened as circumstances required. After punching up the clips there was still a narrow strip of metal left on which the rail rested, though not evenly. On completion, the weight of the sleeper was exactly 69lb., and the two keys were 1¼lb. together, making the sleeper and two fastenings 70¼lb. in all.

The field for invention was still a wide one. Putting on one side the question of weight, which should not be restricted if a good solid road was wanted, but which must, of course, vary considerably according to gauge and nature of traffic, the author believed that a good sleeper should combine the following points: (1) Depth and sectional area sufficient to prevent fracture or permanent set under the load likely to come upon it when in unfavourable conditions as regards ballasting and packing. Danger from fracture was at first much feared when metal sleepers were introduced, but it had been found that breakages did not exceed 1½ per cent. on the Continental lines. (2) The metal should be increased at the rail bearing and bolt holes, if any. (3) The ends should by preference be closed, as it was found that with open ends there was a tendency for the ballast to work outwards and leave a hollow space under the sleeper, and this was more especially the case if the sleeper was bowed, so as to give the inward cant of 1 in 20 to the rail, whereas with a closed end the tendency was in the opposite direction, and the labour of keeping the road in order was minimised. (4) The bolts and nuts employed should be as few as possible; riveting, if it could be done at the works, was preferable for the fastenings; but in foreign work, if the rivets had to be put in on the ground, they were better dispensed with, as the work may be badly done by local workmen. Cutting out a portion of the sleeper to form a clip was not theoretically, at any rate, advisable, not only because the sleeper was thereby weakened, but also because, if the clip was accidentally broken off, the sleeper becomes useless, or else labour and trouble was involved in riveting on a substitute, and this was not easily managed in a foreign country; but if this method of fastening was nevertheless preferred, very special care must be taken in manufacture to provide a sufficiently mild steel, and of course very careful inspection was a necessary consequence. (5) Some provision should be made for altering the gauge within slight limits, and so far as the writer was aware, this at the present time could only be accomplished by the wedge system. (6) All sleepers should be dipped in a solution, if possible, when hot (some engineers advocate roughening the surface with sand to increase the friction, but this is scarcely necessary, as it increases the labour at the works). The advantage of dipping when hot was that a rapid drying took place—a small matter, but one of importance in shipping, as carriers very naturally objected to having a vast mass of material on board in a dirty state, and the smell of the solution affected the rest of the cargo; the labourers, too, at the docks gave trouble, as they occasionally refused to handle the slimy materials sometimes brought down in the trucks. Pressed sleepers could always be dipped hot, as they could be taken from the die direct to the dipping tank, though care had to be taken that the inflammable solution was not set on fire. Rolled sleepers, however, unless re-heated, must be dipped cold, and in that case the inspector should see that the dipping solution was kept at boiling point by a coil of steam pipes, and a sufficient quantity for a cargo laid aside some weeks before shipping was commenced. Stacks should never be allowed to be piled too high, not only to give a free circulation of air for drying, but also to prevent injury to the bottom layers. A dipping solution recommended to the author was as follows, and it would do for rails as well as sleepers: 2 gallons of boiled tar, ½ gallon mineral turps, and 1 gallon vegetable oil. The tar is boiled first, and the other ingredients are then well mixed in. The turps constituted the driers in this preparation, and the larger the proportion of this the more rapidly the drying was effected; but as it was also highly inflammable, great care should be taken if the metal be dipped hot.

CHEMICAL SOCIETY.

Dr. A. K. Miller, in examining Guthrie's compound produced when nitric peroxide acts upon commercial amylene, has proved that the body which is formed is derived solely from the hydrocarbon—trimethyl ethylene—and not from any of the other compounds which are present in the crude amylene. Pentane appears to be also present in the commercial body, but it and normal amylene and normal hexylene do not form crystalline products with nitric peroxide. The author has studied this reaction with a view of ascertaining whether the formation of this compound will afford a means of separating the different hydrocarbons which exist in the products of the manufacture of oil gas, shale spirit, and other complicated hydrocarbon mixtures (see *Industries*, Vol. III., page 433), and experiments are progressing in that direction.

A new method for ascertaining the much vexed question as to whether certain alloys are true chemical compounds or not has been described by A. P. Laurie. By using alloys of known percentage composition, as one of the plates in a small battery, he has measured the difference of potential produced by a quadrant electrometer. In the case of the zinc copper alloys, if the alloy contains less zinc than that which corresponds to the formula $CuZn_2$, a very slight difference of potential is observed; but if the alloy contains a small excess of zinc above that corresponding to this formula, the e.m.f. of the cell is suddenly considerably increased. He considers that this sudden rise is due to the presence of free zinc in the plate, as from previous experiments he has shown that a plate of copper to which a small piece of zinc is attached behaves as a zinc plate, even when the zinc is only one-thousandth the weight of the copper employed. More accurate experiments with the copper tin alloys by a similar method have confirmed the results arrived at by Rieche from an examination of the density of these alloys, and by Lodge and Austen, who have examined their electrical resistance and the effects produced by them in a Hughes induction balance. Laurie's experiments show that the alloy Cu_3Sn, when used in a battery in the place of the zinc plate, gives only a small e.m.f.; but when a greater percentage of tin is present, the e.m.f. rapidly increases, and then remains at more or less of a constant value until the composition of the plate used contains no copper. This method of examination does not therefore give any information as to the existence of the alloy Cu_1Sn which has been previously described. He has confirmed these results by showing that when an alloy containing more tin than is expressed by the formula Cu_3Sn is placed in a copper cup, and surrounded by dilute acid in contact with cuprous chloride, the tin is slowly dissolved out of the mass until it reaches the composition of the alloy Cu_3Sn, which then ceases to be acted upon. His experiments seem to conclusively prove that tin and copper, when alloyed in the proportion corresponding with this formula, form a true chemical compound.

THE ORIGIN OF COLOUR.

A paper on the origin of colour, and the chemical constitution of colouring matters generally, was read by Professor Henry E. Armstrong, F.R.S., at a recent meeting of the Chemical Society in London. The origin of colour in bodies was shown to be closely connected with the affinities of the elements composing such coloured bodies, and therefore to depend on the valency of the elementary substances present, if the term valency be used in its broadest sense. Several chemists have endeavoured to unfold the relationship which must necessarily exist between the chemical constitution of compounds and their colours. Graebe, after his investigation on the constitution of quinone, communicated a paper, in conjunction with Liebermann, to the first number of the "Berichte" of the German Chemical Society on this subject, in which they pointed out that, excluding coloured metallic salts, the colour of organic bodies was destroyed by reducing agents, and that the quinones, all of which are more or less coloured, give on reduction colourless hydroxy derivatives. The constitution of quinone may be represented by the formula $C_6H_4\begin{matrix}O\\O\end{matrix}>$ and that of the hydroxy derivative by the symbol $C_6H_4\begin{matrix}OH\\OH\end{matrix}$ so that the union of the oxygen atoms with one another, represented symbolically by $\begin{matrix}O\\O\end{matrix}>$ appears to be the cause which produces the effect of colour in this class of compounds. A withdrawal of two atoms of hydrogen from the hydrazo compounds similarly produced the azo colouring matters. Rosaniline, rosolic acid, and indigo also yield colourless derivatives on reduction. The arrangement of the oxygen and nitrogen atoms in organic colouring matters has therefore an important influence on the tinctorial properties of the body. At the time when these earlier theories were advanced, the constitution and orientation of several of the more important colouring matters were imperfectly understood, and more recently the view advanced by Fittig that quinone may be considered a double ketone, or a body in which the oxygen atoms are not united to one another, but doubly united to different carbon atoms, has gained ground, and hence the intimate contact of the oxygen atoms in these coloured bodies is not an essential condition for the production of colour. Anthraquinone, the corresponding dioxy-derivative of the hydrocarbon anthracene, has, undoubtedly, the constitution of a di-ketone, and as it is a coloured body, it affords additional evidence for a belief in the view just advanced. In 1876, Otto N. Witt contributed to our knowledge of this subject an important paper on the "Bau und Bildung färbender Kohlenstoff verbindungen," in which he summarised the views he then held in the following laws: (1) The tinctorial properties of an aromatic organic compound is due to the presence of a colour giving and a salt forming group in the compound. A colour giving group is called a "chromophore," and he cites the radical NO_2 as an example, while amidogen NH_2 and hydroxyl OH are examples of the salt forming groups. A body containing a chromophore is called a "chromogen," thus in nitraniline $C_6H_4(NO_2)(NH_2)$ and nitrophenol $C_6H_4(NO_2)(OH)$, the chromophore is the NO_2 group, and the chromogen of these bodies is nitrobenzene $C_6H_5(NO_2)$. (2) Bodies which contain a chromophore are more coloured when they are in the form of salts than in the free state. (3) The more stable the salt, the more coloured is the compound—when the same chromophoric base is employed. Aniline, to take a further example, is a colourless base, and contains no chromophore; when nitrated by the introduction of the chromophore NO_2 the coloured nitraniline is produced, and its salts vary in colour with their stability. In colouring matters of this class, it has further been noticed that the two groups present—the NH_2 and NO_2 in the example taken, are in the same position as are the oxygen atoms in quinone, and known to chemists as a "para" or 1 : 4 compound. The two other nitranilines have not the same tinctorial properties as has the para compound. Although chromogenic bodies are converted into dyestuffs by the introduction of such groups as NH_2 or OH, if these groups are altered by substitution of their hydrogen atoms, the colour may be considerably modified. Thus a chromogen containing the group NHAc or OMe in the place of NH_2 or OH is colourless, as the basic nature of the compounds is reduced. If on the other hand the body contains the group NHMe in the place of NH_2, the colour remains, and the compound is still basic. Phenolphthalein does not dye, while fluorescein gives a fugitive yellow colour. If fluorescein, which is a weak acid, be nitrated or brominated, it is thereby converted into a strong acid, and can then form strong and valuable colours, of which the eosins may be taken as a type. Similar reasoning may be applied to the nitrophenylamine and azo colouring matters. The origin of colour may not, however, be due to the same or similar causes which make the body a dyestuff. The dominant idea which seems to underlie these speculations is that the union or valency of the elements present conditions the colour of the compound produced. The paraffins with single affinities are inert and colourless, not only in the visible part of the spectra, but also in the ultra violet and ultra red portions, as shown by the spectroscopical investigations of Abney, Festing, and Hartley. When two atoms of hydrogen are withdrawn from a paraffin and an olefine is obtained we have more active compounds produced and a beginning of colour is manifested spectroscopically, and with a further withdrawal of hydrogen, as in the acetylenes, a still greater absorption of light takes place in the compounds produced. The colour of compounds may therefore be due to a condition of strain within the molecules, as Baeyer some years ago endeavoured to explain the properties of the acetylene compounds by the assumption that the affinity of the elements has direction, so that in compounds in which carbon atoms are "doubly" or "trebly" bonded together there was a displacement of the direction of some of the valency of the carbon atoms, which renders the compound liable to decomposition and capable of readily forming addition products. A carbon atom may, according to Baeyer, have its valency distributed in space in the same way as are the angles of a regular tetrahedron inclosed in a sphere. Ostwald has advanced a similar view, and Armstrong has pointed out in the "Philosophical Magazine" that the saturated hydrocarbons have the valency of their carbon atoms unstrained and therefore free to act in certain directions, while in the unsaturated compounds a strained condition exists, rendering the bodies active and of comparatively easy separation. Water, although viewed by the majority of chemists as a saturated compound, is able to unite as water of crystallisation and in solution by virtue of what is termed residual affinity, and it is coloured as shown by the researches

Digitized by Google

of Russell, Abney, and others. Nitric peroxide NO_2 similarly is coloured and unsaturated, while its polymer N_2O_4 is saturated and colourless. The unsaturated body is at a comparatively high potential and runs down, forming the saturated colourless body of low potential. Similarly, oxygen is colourless, while the unstable ozone is coloured. The higher oxides, as a rule, have greater colour than the low oxides of the same metal; as an example, the three oxides of lead may be cited. With the titanium oxides, the stable dioxide TiO_2 is white, while the unstable TiO and TiO_3 are blue and yellow respectively. In the manganates and permanganates the high tinctorial power of these bodies seems to be due in some way to the large amount of oxygen that they contain. In the darkening of sulphur on heating, we have an example of the formation of simpler molecules of high potential. Sulphur, again, unites with sulphuric anhydride to form a blue liquid, while selenium similarly combines with the same body to form a green compound, and tellurium a red one. Many of the coloured iodides of the heavy metals unite with the alkaline iodides to form colourless salts with the evolution of heat, and the coloured metals, gold and copper, similarly alloy with tin, forming colourless chemical compounds. Among the carbon compounds there is no example of a coloured hydrocarbon, and most of the derivatives containing monad radicles are likewise colourless. The strained condition which is, according to the view advanced by Professor Armstrong, necessary for the production of a coloured compound, is fulfilled in the organic dyestuffs, if they be considered all derived from a quinonic type, and the more important groups of colouring matters, viz., the azo compounds, rosaniline and rosolic acid, phthaleïns, methylene blue derivatives, and indigo may be so regarded.

ALLOYS AND THEIR PROPERTIES.

The third and last of the series of Cantor lectures on the above subject, by Professor Roberts-Austen, at the Society ofArts, was delivered on the 26th ult., on the colours of metals and alloys, with illustrations principally derived from Oriental art metal work. Twenty-four years ago the accomplished antiquary, Mr. William Burgess, in a course of Cantor lectures, dealt incidentally with the subject of art metal work. Those lectures were considered so important that the present director of art at South Kensington, Mr. T. Armstrong, made them the text for an address delivered before the Society of Arts in February of last year, in which he reviewed the progress that had been made in applied art in the time which had elapsed since the writings of Burgess.

Professor Roberts-Austen, in considering the principal facts connected with the colours of metals and alloys, gave a brief description of the kind of influence which the colours of metals appear to have exerted on the history of chemical science. The lecturer observed that the colours of the seven metals known to the early metallurgists were believed to be influenced by the seven principal planets, a belief which was not completely abandoned until a comparatively late period. He described the alteration in appearance of tin by the presence of a small quantity of mercury, and also the absence of the yellow colour of gold under the influence of lead or mercury. Gold itself was capable of existing in nearly all the colours of the spectrum—purple to green, yellow, bright red, and dark brown nearly to black.

Besides those colours which belong naturally to metals and to their alloys, certain other tints may be produced on their surfaces by artificial means, and this is especially the case in regard to alloys of copper. The Japanese art metal workers have for centuries used alloys of copper containing small quantities of gold, antimony, cobalt, and other elements, in the manufacture of those beautiful specimens of handicraft for which they are so renowned. The surface tints produced on these alloys are obtained by the action of certain "pickling" solutions, the various compositions of which were given by the author, who, by their aid, had prepared a trophy of richly coloured leaves. A series of paintings showed the different colours produced by the same pickle on copper containing 3 per cent. of specified impurities; and when the impurity was reduced to three-tenths per cent. the effects were, in a modified degree, almost the same. Reference was made to fifty-four plaques from Japan in South Kensington Museum, as showing what can be done in obtaining coloured metallic surfaces by the judicious use of pickling solutions.

Attention was then directed to the singular banded alloy known as Moku-me, or wood-grain, the manufacture of which is now almost abandoned by the Japanese, but which the author is anxious should be introduced into this country. Specimens of this somewhat scarce work were exhibited. Reference was also made to the possibility of depositing coloured alloys by the aid of electrolysis, and it was incidentally stated that one firm deposited annually 6 tons of silver in films of such thinness that if spread out they would cover an area of about 140 acres. The lecture consisted mainly of a plea for colouring metals by the elaborate methods of the Japanese, and for the use in casting, by the method of circ-pendue, complicated alloys which either possess or are capable of receiving rich tints. The formation of the beautifully coloured films obtained on the surface of lead by heating it in air was shown experimentally, and in reference to this the lecturer pointed out the important part it had played in the history of metallurgy, even to the discovery of oxygen. Professor Roberts-Austen, after one or two references to the poets, concluded his lecture with the remark that "it was the coloured show of dross which was the basis of all modern chemistry."

THE CHEMICAL EXAMINATION OF RESINS.

The various resins used in the preparation of varnishes are usually recognised rather by their physical properties of colour, hardness, weight, and melting point than by their chemical reactions. Many chemists have, however, within the last few years been investigating this subject, partly from a theoretical point of view, and partly in the hopes that some simple analytical method may be devised for determining the true value of a sample of any resinous body. The resins include a large class of gums and vegetable products of different chemical composition, and little is at present known with regard to their constitution. The microscopical structure of a resin also often affords a ready means of approximately determining its nature, and has been dealt with, together with so much as was then known of the chemical behaviour of these bodies, in a work by Herr Wiesner, entitled "Die Technisch Verwendeten Harze und Gummiarten." In this book we find enumerated the solubilities of the various resins in different solvents, and their behaviour towards the common alkalies, concentrated sulphuric acid, and the odours described which are obtained on warming and burning most of them. Herr Schmidt and Erbau have endeavoured to develop what we may term the analytical examination of resins, and the methods employed by them, and their more important results, seem to be of importance to those engaged in this branch of technology.

Herr Köttstorfer and V. Hübl drew attention to the fact that the resins are saponified by boiling with a solution of potash dissolved in alcohol, and that a given resin required always approximately the same amount of a standard solution of such alcoholic potash to effect its decomposition. The quantity of potash consumed in this way will be therefore a rough measure of the purity of a given sample of a resin, if one be acquainted with the amount required when a genuine specimen is used. The resins, when dissolved in alcohol, give solutions which are slightly acid, and this acidity can be readily estimated by titration with a standard solution of alcoholic potash. The real amount of potash required to effect the saponification of the resin will therefore be the difference between this number and Köttstorfer's, which obviously gives the amount of potash required to first neutralise and then saponify the resin. A third important reaction has also been put into a quantitative form by Herrn v. Schmidt and Erbau. Resins combine with iodine. Therefore, by adding a standard solution of iodine to a known weight of resin, and determining the amount consumed by titrating the residual quantity of iodine with a standard solution of hyposulphite of soda, we get a third number, which gives us information concerning the quality of the resin under examination. This standard iodine solution is prepared by dissolving 25grm. of pure iodine in 500 cub. cm. of alcohol, free from fusel oil, and adding it to a clear solution of 30grm. of mercuric chloride in the same quantity of alcohol. The other solutions employed are standard solutions of half normal hydrochloric acid and caustic soda, and a solution of hyposulphite of soda, containing about 24grm. in the litre. A semi-normal potash solution in alcohol is also required, and is made by dissolving 25grm. of caustic potash in the least quantity of water, and then diluting with alcohol until the volume is one litre. Phenol-phthalein in alcoholic solution is used as indicator in determining the amount of soda consumed. About 1grm. of the finely powdered resin is sufficient for each experiment. The numbers obtained when titrating the resins with alcoholic soda show a marked difference with different kinds of resin. Colophonium is the most strongly acid, and then follow sandarac, gum benzoin, and storax, while shellac, mastix, and dammar cause only a very slight acid reaction. The copals behave differently fused, white copal from Angola having a greater acidity than the red variety, while that from Zanzibar is neutral. Shellac requires the largest amount of alcoholic potash to effect its saponification, while elemi, Zanzibar copal, asphalt, and fused amber only consume a small quantity of the caustic. Venetian turpentine uses the largest percentage of iodine, and this substance and colophonium are the only two resinous bodies so far examined which consume more than one hundred parts of the iodine solution. Dragon's blood, mastic, storax, and gum benzoin require nearly equal amounts of this reagent, while shellac, fused amber, the copals, and asphalt are represented by low numbers. The resins, when purified from their solutions in alcohol or oil of turpentine, by precipitating them by means of steam, give different numbers, which afford a means of checking those obtained from the natural product. When two or three resins have been mixed together for commercial purposes, a convenient method for qualitatively determining what resins are present is based upon their different behaviour with certain solvents. Alcohol does not dissolve amber or the copals, except red and white fused Angola, which is partly soluble; while mastic, shellac, sandarac, elemi, Venetian turpentine, colophonium, and gum benzoin are readily soluble, while asphalt, dammar, dragon's blood, and storax are only slightly soluble in this solvent. After having effected a partial separation by means of alcohol, the behaviour of other solvents, such as benzole, carbon bisulphide, ether, ligroin, acetone, and amylalcohol is observed, and in this way all the common resins are easily identified. Shellac is the only resin which is not soluble in chloroform. By means of the quantitative method which we have briefly described, it is possible to ascertain the amount of mastic in a mixture of sandarac and mastic, or of shellac, when mixed with colophonium, or the amount of colophonium, dammar, and mastic, in a mixture of the three. Similar results to those of Schmidt and Erbau have been obtained by Dr. Kremel, proving that these methods are reliable, and therefore of commercial value.

Notes.

NATURAL GAS AT NEWCASTLE.

Last June a "blower" of natural gas was struck in the underground workings of the Hebburn Colliery, near Newcastle-on-Tyne, and remained for fully six months a source of annoyance and danger to all in the pit. At the commencement of the present year—as the flow seemed likely to be permanent—it was decided to utilise it by running a 6in. pipe from the "blower" to the surface, and burning the gas in one or more boilers. On the 26th of February the gas was successfully lighted in a large Lancashire boiler, which has continued to work steadily ever since. It is believed that the flow is sufficient to supply four boilers, and three others are accordingly to be connected with the gas main. The gas is introduced to the boiler flue by an annular burner, the flame being afterwards broken up and spread by a brick bridge placed about 7ft. from the front end. The evaporative power of the gas is great, and the arrangement, when complete, is expected to result in a saving for fuel and labour of about £3,000 per annum.

THE ELECTRIC LIGHTING OF THEATRES.

The Riga Theatre has been fitted with an electric light installation of considerable size. The motive power is steam, supplied by three locomotive boilers, each of 760 sq. ft. heating surface, and working at 105lb. pressure. In the engine room are erected three single cylinder high pressure steam engines, with Rider's cut-off gear, each engine developing 65 effective horse power, and driving a glow lamp dynamo of 37 kilo.-watts. The three large dynamos are collectively capable of lighting 1500 20 c.p. glow lamps; but as only 1000 lamps are required for night use the third dynamo is in reserve. For the day service, when only 142 lamps are required, there is provided a separate small dynamo, driven by a 12 h.p. steam engine. The exhaust steam from all the engines is passed through a tank, where a large portion of it is condensed, so as to raise the temperature of the feed water. The boilers are fed either by a steam pump or by three injectors. There are in the theatre three distinct circuits—one for the day service feeding 142 lamps, and the two others for the night service feeding collectively about 1000 lamps, and a switch board is erected by means of which either of the large dynamos can be connected to either of the two night circuits. The lamps are distributed between these two circuits so as to overlap each other, in order that either circuit may form a panic circuit in case of the extinction of the other. The total number of lamps installed considerably exceeds the capacity of the dynamos, but the distributing switches are so arranged that it is impossible to light all the lamps simultaneously. On the stage there are fixed 1162 lamps, of which 550 can be lighted simultaneously, whilst 612 lamps serving for red and blue lights can be switched in when the others are extinguished. The large corona in the auditorium contains 124 lamps, and 56 lamps are distributed round the tiers. In addition to these there are 272 10 c.p. lamps fixed in the engine house and offices, and two 1000 c.p. arcs in front of the theatre.

23rd March, 1888.

4441. Sage, F. C. — Hansom cabs (*Sage*).
4443. Bamford, S. B. — Wheels and shafts for horse rakes.
4445. Jardine, J. — Bearing for taking up wear and preserving a perfect cylindrical surface.
4450. Barber, F. — Water gauges of steam boilers (*Barclay*).
4451. Darling & Sellers — Machine tools.
4452. Smith, T. F. — Cranes.
4453. Shakeshaft, J. — Railway signalling.
4462. Brown, A. T. G. — Sleepers for railways.
4464. Fear, E. J. C. — Ship's anchor (*Munn*).
4467. Bentall, E. H. — Lawn mowers.
4468. Felt & Felt — Lubricators.
4473. Fox & Lighthall — Tramways.
4474. Dukes, B. — Structures for supporting electric conduits (*Hart*).
4475. Marelle, M. R. — Automatic registering apparatus.
4480. Linnenbrügge, A. W. F. G. — Propelling and steering ships.
4481. Klau, K. — Machine for harvesting potatoes.
4482–3. Leake, C. F., & others — Manufacture of floor cloths.
4486. Woodward, L. — Knitted fabrics.
4488. Rugeroni, A. E. — Dredging apparatus.
4490. Evans & Harrison — Transferring metal from one set of rolls to another.

24th March, 1888.

4497. Hackett & Hackett — Crane.
4499. Cadenhead, G. — Screw propellers.
4500. Jones, E. W. — Injectors.
4503. McConnel & Higginson — Grinding the flats of revolving flat carding engines.
4504. Thornton, J. T. — Machines for shearing cloth.
4505. Ashworth & Ashworth — Flattening or shaping wire for cords.
4514. Whitaker, G. — Propulsion of boats.
4515. Warsop, H. J. — Gas engine.
4516. Robinson, F. — Manufacture of pile fabrics.
4517. Rushworth, S. P. — Steam and hot water heating apparatus.
4520. Longsdon, H. C. — Mangling machines.
4525. Parker, F. — Saw machines.
4526–8. Mann, J. J., & others — Apparatus for dressing stone.
4531. Bourne, J. — Motive power engines.
4539. Correa, F. — Rotary pumps.
4540. Donisthorpe & Towns-end. — Twisting and winding frames.
4543. Gell, W. J. — Apparatus for raising and lowering boats.
4546. Gill, A. — Apparatus for lifting and transporting stone.
4548. Singleton, T. — Brake wheels, stop rod, and strap fork joint for looms.
4551. Haddan, R. — Saw setting and sharpening machines (*Titscher*).
4552. Apraxin, Count A. — Transporting loads by the aid of balloons.
4558. Nation, W. B. — Preparation of fibre from rhea grass.
4560. O'Donnell, J. P. — Railway signalling apparatus.

26th March, 1888.

4565. Smith, W. — Cutting and dividing double piled fabrics.
4570. Howarth & Horrocks — Boiler furnaces.
4572. Hattersley & Hill — Let-off mechanism for looms.
4576. Sowden, A. — Pattern pegs of looms.
4580. Hancock, E. — Hand lever presses for hay.
4582. Lings, W. — Pressing hay by hand power.
4586. Crook, P. — Mules.
4589. Nicholls, A. — Breech loading and machine fire arms.
4590. Dent, R. A. — Prevention of incrustation in steam boilers.
4599. Day & Ward — Ratchet drill brace.
4601. Vering, H. — Dredgers.
4602. Tilden, H. — Heating tube for furnaces.
4603. Boldt & Vogel — Cork sizing machine.
4605. Horsburgh, R. — Burglar and fire proof safes.
4606. Fehlen, A. — Apparatus for generating motive power.
4607. Wallis, J. E. — Thrashing machines.
4615. Sjövall, B. — Valve gear.
4618. Avery, W. B. — Weighing apparatus.
4621. Boult, A. J. — Type writers (*Downey*).
4624. Crossley, F. W. — Governing gear for gas engines.
4633. Tommis & Whitwham — Water gauges of steam boilers.
4637. Tellier, C. — Utilising waste heat for producing motive power.

27th March, 1888.

4646. Harrington, F. T. — Two wheeled road carriages.
4651. Horrocks, D. — Hot water circulating boilers.
4654. Whitehead, J. — Self acting mules.
4657. Yeadon & Middleton — Disintegrators.
4662. Shackleton, R. — Heating feed water.
4664. Petrie & Fielden — Drying textile material in the skein.
4670. Richards, G. B. — Ships' stems and buffers.
4675. Hartley, H. — Dressing and winding-on frames.
4677. Reichling, R. — Vapour condenser and water purifier.
4680. Clark & Reid — Flue tubes for steam boilers.
4681. Eames, H. H. — Pulverising ore.
4689. Rathbone, A. — Machines for heating, cooling, or condensing fluids.
4690. Walsh, G. — Mules.
4698. Bergh, W. — Centrifugal fluid separating machines.
4704. Bruce, W. P. — Manufacture of paper.
4707. Lake, H. H. — Generating steam (*Adams*).
4708-9-10. Lake, H. H. — Generating steam (*Peck*).
4719. Gerry, S. — Registering vacuums in condensers of engines.

28th March, 1888.

4729. Arnold, E. J. — Type writing machines.
4732. Wilkinson, E. — Feeding wool and other fibre to carding machines.
4733. MacLaine, A. — Heating feed water.
4736. Hargreaves & Inglis — Bearings for shafts.
4738. Wilson, J. P. — Ships' boats.
4740. Ridealgh & Fairman — Gas and vapour engines.
4746. Shann, G. — Pendant shafts.
4753. Walsh, J. — Presses for packing hay.
4755. Kenyon, H. B. — Supplying towns with sea water.
4761. Adnet, P. — Manufacture of pitchforks.
4762. Guhl, H. — Sewing machines.
4763. Drde, H. — Railway car couplings.
4768. Hawke, J. — Manufacture of blotting paper.

29th March, 1888.

4775. Row, O. M. — Evaporation and condensation of sea water.
4778. Walker, W. H. — Straightening and tempering circular saw plates.
4779. Inman, C. B. — Bottle washing machines.
4785. Roger, G. — Apparatus for cutting piled fabrics.
4786. Petrie & Petrie — Cleansing wool.
4789. Benton, C. H. — Governing gear for steam engines.
4793. Newell, J., & The Leicester Co-operative Hosiery Manufacturing Society — Taking up and delivering the machine stitch in flat rib fabrics.
4795. Waldecker & Sandt — Sewing machines.
4796. Smith, D. — Straightening and cutting off wire.
4798. Dack & Barlow — Raising vessels from one canal to another.
4799. Livingstone, R. — Core making machines.
4803. Fox, E. — Distributing explosive matters in motive power engines.
4805. Stevens & Major — Lifting and winding machinery.
4812. Murrie, J. — Motive power engines.
4813. O'Neill & O'Neill — Pneumatic tram car locomotives.
4815. Ibeson, S. — Heating and drying chambers.
4817. Jordan, T. N. — Machine for dressing lace.
4821. Gastrell, J. P. H. — Rotary engines.
4822. Newton, P. A. — Improvements in printing type (*McClure & Vivian*).
4826. Bade, C. — Acoustic signalling apparatus.
4828. Wood, A. M. — Life boats.
4829. Wilmott & Wilmott — Wire netting machines.
4836. Hayward, J. W. — Apparatus for signalling.

ELECTRICITY.

23rd March, 1888.

4489. Lauckert & Haensel — Electrical glow lamps.

24th March, 1888.

4523. Kelman, J. — Telegraphic and telephonic apparatus.
4524. Barber-Starkey, W. J. S. — Portable galvanic batteries.
4559. Wolffers, F. de — Electric arc lamps.
4561. Brown, C. A. — Battery jar.

26th March, 1888.

4568. Williams, S. — Conductors for electrical purposes.
4579. Dillon, J. J. — Electrical alarum.
4593. Rawson, F. L. — Electrical batteries.
4596. Von Besserer, G. — Preventing oscillation of saloons on board ship.
4604. Pyke & Barnett — Continuous opening and closing of electric circuits.
4626. Hoepfner, C. — Electrolytic production of metals.
4627. Wells & Goad — Incandescent electric lights.

27th March, 1888.

4659. Schmidt, F. T. — Electrical alarm.
4673. Justice, P. M. — Generation of electric currents (*Heisler*).

28th March, 1888.

18036. Pope, W. R. — Coin operated induction coil. (Received March 28th, 1888. Ante-dated August 31st, 1887, under International Convention).
4730. Venables, G. — Electromagnetic time piece.
4759. Lake, H. H. — Telephonic apparatus (*International Dudley Signal Co.*).
4764. Fry, A. L. — Portable galvanic batteries.

29th March, 1888.

4804. Piper, E. J. — Switching arrangement for electric signalling, &c.

CHEMISTRY.

23rd March, 1888.

4476. Johnson, J. Y. — Blue colouring matters (*Badische Anilin & Sodafabrik*).
4485. Maddick & Greenwood — Extracting gold and silver from ores.
4594. Bennett, J. A. B. — Alloys.
4595. Bennett, J. A. B. — Aluminium chloride.

26th March, 1888.

4625. Abel, C. D. — A new alpha-naphthol-disulphonic acid (*Actien Gesellschaft für Anilin Fabrikation of Berlin*).

27th March, 1888.

4648. Parnell & Simpson — Production of sulphur from sulphuretted hydrogen.
4653. Davis, G. E. — Producing carbonates and hydrates of the alkalies.
4694. Lane & Delmard — Soda water.
4699. Bohm, W. D. — Expulsion of chlorine from solutions.

28th March, 1888.

4765. Hobson, A. H. — Treatment of bones and animal waste for obtaining gelatine, glue, and size.
4767. Kingzett, C. T. — Manufacture of chlorine

29th March, 1888.

4784. Player, F. — Cleaning and polishing tin and terne plates.

MISCELLANEOUS.

23rd March, 1888.

4438. Tomkins, J. D. — Separation of cotton from the husks.
4448. Hammond, J. G — Mounting stereotype.
4455. Nicholls, A. — Tools for the production of tapers for screws or plugs.
4458. Maples, T. W. — Fire proof case for storing explosives.
4459. Kjöllerfeldt & Kolnotsch — Machines for making cigarettes.
4461. Burrage, G. H. — Extinguishers for lamps.
4466. Sykes & Cook — Valve for water.
4471. Bowman, R. D. — Lamps.
4478. Bernreuther and Kumpfmiller — Washing and steeping barley.
4484. Wren, J. E. — Illuminating gas.
4487. Accles, J. G. — Boxes for containing cartridges.
4491. Edwards, E. — Safety lamps (*Verschuren*).
4492. Appleby, C. — Packing for joints between metallic surfaces.
4493. Sizer & Sizer — Ventilators.

24th March, 1888.

4496. Rowbottom, S. — Fastening or joining tapes or belts.
4502. Wenger, A. F. — Process for decorating pottery.
4507. Stewart, W. — Decolorising animal and vegetable oils and fats.
4521. Robinson, L. J. — Manufacture of felt hats.
4537. Germeuil-Bonnaud, J. B. — Photographing in colours.
4544. Bouverie & Balch — Life saving appliances.
4549. Nicoll, D. — Oil lamps.
4554. Taylor, F. E. V. — Nails.
4555. Greaves, T. — Bronzing and polishing pad.
4556. Penn, W. J. — Wind gauge for fire arms.

26th March, 1888.

18035. Kempster, D. E. — Rowing tricycles. (Received March 26th, 1888. Ante-dated September 13th, 1887, under International Convention).
4566. St. George & St. George — Watches and clocks.
4569. Garthwaite, J. S. — Automatic safety gas trap.
4571. Hopkinson & Hopkinson — Velocipedes.
4575. Milnes, J. — Warming railway carriages.
4585. Bennett, H. H. — Cee spring.
4597. Curson & Curson — Door lock furniture.
4608. Arnold, A. E. — Manufacture of compressed leather.
4609. Glew, F. H. — Porous surfaces for the absorption of liquids and gases.
4610. Lloyd & Priest — Velocipedes.
4611. Calvert, E. A. — Fire escapes.
4614. Wehlen, G. P. — Watches and travelling clocks.
4616. Bernreuther & Kumpfmiller — Maceration of barley.
4617. Spence & Spence — Fire resisting materials.
4619. Cavill, F. — Horse shoes.
4620. Black, J. M. — Ticket punches.
4629. Godson, W. D. — Valve tap.
4630. Daniell, H. E. — Metallic packing for pistons.
4632. Cawkwell, H. A. — Manufacture of tiles.
4635. Redfern, G. F. — Plastic composition (*Fabregues*).
4636. Redfern, G. F. — Fire escape (*Des Masures*).
4639. Cox, R. — Manufacture of candles.

27th March, 1888.

4641. Greene & Claffy — Cores for tubes.
4642. Bell, A. C. — Ball or float valves.
4644. Bridge, L. — Sliver cans.
4645. Mackay, F. N. — Ice machines.
4656. Yeadon & Middleton — Briquettes of fuel.
4661. Shackleton, R. — Consuming smoke.
4663. Whittle, W. — Chimney cowls.
4667. Mechan, A. — Flange joints for pipes.
4668. Le Patourel & Hyams — Barometer.
4669. Randell, J. — Key for securing rails in chairs.
4674. Ryland & Green — Packing cases.

Digitized by Google

4678. White & Brookes ..... Manufacture of boots.
4679. Clark & Reid ..... Coating of metallic tubes.
4684. Boult, A. J. ..... Fire extinguishing fluid (*Monmon*).
4685. Thompson, W. P..... Watches (*Terstegen*).
4686. Bulpitt, W. H. ..... Lamps.
4688. Horton & Horton..... Straightening steel wire.
4691. Robert, J. L. ..... Bottles.
4693. Friedrich & Graesser. Bottles.
4696. Schenck, U. H. W. ..... Belt shifters.
4697. Howard, R. L., & others Ball cocks for water waste preventers.
4700. Nicol, H. L. S..... Registering the quantity of liquid drawn from casks.
4701. Brown, T..... Bobbins for winding yarns.
4702. Block, W..... Fire escape.
4703. Haddan, H. J. ..... Belt fasteners (*Gingras*).
4705. Kilvert and others ... Making boxes of cardboard.
4713. Bowman, R. D..... Regulator for the supply tubes of liquid hydrocarbon lamps.

28th March, 1888.

4720. Shufflebottom and Brown ..... Bradawls.
4722. Baker, F. R..... Oil lamp burners.
4725. Craven, W. ..... Raising woollen cloths.
4731. Babington, H..... Taps.
4734. Clough, J. ..... Velocipedes.
4735. Walder, C. R..... Vices.
4742. Rickaby, A. A..... Oil can.
4744. Bouverie & Balch..... Rocket apparatus.
4747. Lemaire, V. D. A. ..... Hinges.
4752. Stratford, T..... Iron blocking spindles.
4760. Maignen, P. A..... Automatic separator and purifier.
4766. Johnson & Hutchinson Filter presses.
4769. Radelet, F. ..... Heater for railway carriages.
4773. White, W. J. ..... Tiles.

29th March, 1888.

4777. Button & Binner ..... Glass bottles.
4780. Smith, F. J. ..... Mercury pumps.
4787. Rabbit, W. ..... Automatic fire extinguisher.
4791. Barton, F. A. ..... Diving apparatus.
4797. Enright, J. ..... Oil lamps.
4808. Bulpitt, W. H. ..... Lamps.
4810. Dearlove & Davies ... Velocipedes.
4818. Roger, J. ..... Drying, withering, and re-firing tea leaf.
4823. Phillips & Stephan ... Photo-lithography.
4824. Bohm, W. D..... Accelerating the passage of liquids through filter beds.
4827. Bade, C..... Extinguishing fire.
4831. Nickels, B. ..... Filtering funnels.
4833. Lindsay, W. ..... Manufacture of artificial fuel.
4835. Schröder & Stuart ... Telescopes.

COMPLETE SPECIFICATIONS ACCEPTED.

Persons interested in opposing the grant of the following patents may give notice of opposition at any time within two months after the dates given.

ENGINEERING.

31st March, 1888.

4444. Holden, J. ..... Brake wheel and loom side for looms.
4843. Stevens, E. ..... Gas engines.
6173. Hadfield, R. A. ..... Toughening steel.
6254. Tolson, G..... Drying fabrics and fibres.
6355. Bown, W. ..... Wheels.
6446. Ross, W. ..... Boot and shoe machinery.
6456. Wright, S. ..... Preparing and jointing staves for casks.
6457. Wright, S..... Making casks and barrels.
6499. Lake, H. H. ..... Coupling railway vehicles (*Tamm and Bührlen*).
6558. Sellars, J. C. ..... Obtaining rotary motion.
6659. Read, R., & others ..... Wiring the rims of sheet metal articles.
6726. Bairstow & Bairstow Distributing oil upon wool whilst being fed to drawing frames.
6768. Bramall, C..... Smelting & converting furnace.
6772. Marsh, F..... Starting tramway vehicles.
6804. Johnson, J. Y..... Sawing stone (*Auguste*).
6846. Myers, F. ..... Type writing machines.
6938. Garvie, J..... Agitators for pumps used in dredging.
6951. Brinjes, J. F. ..... Grinding hard substances.
7091. Robinson, T..... Dressing flax.
7141. Lake, H. H. ..... Grinding mills (*Zonca & Bella*).
7271. Wilson, J. H. ..... Starting of tram cars.
7280. Orr & Brown ..... Metal sheets applicable to the construction of buildings.
7439. Haddan, P..... Machinery for grinding spherical balls (*Richardson*).
7477. Bash & Bash..... Ironing machines.
7507. Lake, H. H. ..... Elevated railways (*Otto*).
7538. March & Dick..... Nail making machines.
7556. Lockwood, K. ..... Dyeing yarns.
7562. Laycock, W. S..... Brakes.
7609. Siemens, F. ..... Ceramic kilns.
7623. Green, Sir E. ..... Scrapers of fuel economisers.
7671. Harrington & Hopper Wheels.
7672. Crossley, F. J..... Propellers.
7716. Evans, P. ..... Steam generators.
7746. Darling, T. ..... Machinery for breaking stones.
7887. Barthel, A. E..... Elevated railway.
7935. Ridley & Blackmore... Landing stages.
7993. Denille, L. A. ..... Manufacture of tacks and rivets.
8042. Ludwig, H. E. ..... Wheels and pulleys.
8054. Little, G..... Pulverisers.
8486. O'Donnell, J. P. ..... Railway signal apparatus.
8633. Kenway, W. E..... Points for tramways.
8865. Edwards, E..... Separating textile fibres from the stalks (*Maizier & Reitz*).
9137. Inman, C. B..... Bottle washing machine.
9270. Girdwood, H. M..... Treating rhea and other fibres.
11666. Robertson, S. ..... Metallic plates.
12878. Marshall, A. D. ..... Automatic steam trap.
14199. Henderson, C. J..... Furnaces.
16529. Bond, S..... Manufacture of bricks, tiles, and quarries.
17798. Lake, H. H. ..... Grinding mills (*Coles*).
1675. Girdwood, H. M..... Treating rhea and other fibres.
2118. Bayrer, W. J. ..... Shears for metal.
2468. Stevens & Stevens ... Harrows.
2531. Boult, A. J. ..... Storm doors for buildings.
2560. Grout & Bowers ..... Sewing machines.
2896. Riley, J. ..... Basic hearth steel furnaces.
2899. Riley, J. ..... Regenerative furnaces for steel making.
3082. Fouquemberg, N. ..... Machinery for agglomerating fuel.

ELECTRICITY.

31st March, 1888.

4220. King, J. W. ..... Measuring electric currents.
4447. Elwell, P. B. ..... Apparatus for measuring, indicating, and recording currents of electricity.
4832. Liepmann, H. ..... Electrodes for primary batteries.
3097. Drake & Gorham ..... Secondary batteries.

CHEMISTRY.

31st March, 1888.

7504. Typke, P. G. W. ..... By-products from phosphorus compounds.
7833. Johnson, J. Y..... Preparation of naphthazarine (*The Badische Anilin und Soda Fabrik*).
16329. Rainbow, F..... Manufacture of soaps.
17925. Groth, L. A..... Black liquids for dyeing (*Collin and Errani*).

MISCELLANEOUS.

31st March, 1888.

4458. Barker, W. ..... Die for brick making machines.
4490. Seegrün, O..... Regenerative gas lamps.
4915. Trenemen, W..... Photographs in colours.
5016. Neumann & Kühne..... Scissors, shears, and tongs.
5035. Jefferies, H. ..... Manufacture of coal gases.
5129. Taylor, J. M. ..... Velocipedes.
5188. Syer, M. ..... Water waste preventer.'
5425. Bertram, W. ..... Mechanism for drying paper.
5815. Lodge, T. H..... Portland cement.
5940. Easthope, A. ..... Velocipedes.
6028. Schanschieff, A..... Miners' safety lamps.
6261. Buchanan, J. ..... Drying and granulating sugar and salt.
6300. Bethell, W..... Packing for stuffing boxes.
6342. Downing, G..... Coke ovens (*Bauer*).
6583. Hutchinson, R. ..... Polishing powder.
6796. Tissier, P. ..... Stoppering of bottles.
7094. Tatham, W. ..... Belts for cone drums.
7113. Horne & Hollyman ... Warming and ventilating houses.
7238. Abbey, F. F..... Circulation of air in main drains.
7275. Bird, J..... Water draught and dust proof joint.
7279. Watson, J. D. ..... Enamelling of metallic surfaces.
7608. Lake, H. H. ..... Explosives (*Wohanka & Co.*)
7696. Heys, W. E. ..... Ventilating fans (*Steinberg*).
7792. Hall & Hall ..... Fire extinguishers.
7813. Bosshardt, F. ..... Filtering and refining sugar (*Bocquet*).
7867. Fraser & Snodgrass... Distilling apparatus for shale.
8024. Stevenson, J. ..... Preservation of woods (*Salvat*).
9939. Born, P..... Cooling the air in rooms (*Maring*).
12099. Toy, J. ..... Bicycles.
17002. Lowdon, J. C. ..... Check punches.
17103. Lanvin-Schraen, E. I... Tanning.
201. Thompson, W. P..... Wood type (*Setchell*).
838. Sayer, R. C..... Rain water filtering and storing apparatus.
1597. Seebold, M..... Belt fasteners.
2258. Fowler, A. B. ..... Heel burnishing machines.
2353. Zahn, W. ..... Tanning.
2434. Peebles, D. B..... Regulating the pressure of gas.
2597. Lake, H. H. ..... Manufacture of gas (*Humphreys*).
2692. Henderson, N. M. ..... Miners' safety lamps.
2702. Fletcher & Clare..... Gas fires.
2748. Baldwin, E. S..... Nail for corrugated plates (*Davenport*).
2864. Johnson, T. ..... Serving rope for the rigging of ships.
3021. Blakesley, T. H..... Barometer.

PATENTS VOID THROUGH NON-PAYMENT OF RENEWAL FEES.

(To the 24th December, 1887, inclusive.)

Year 1883.

5772. Clymer, D. R..... Ceilings and floors of buildings.
5775. Alison, H. J. ..... Transmitters for printing telegraphs (*Field*).
5777. Alison, H. J. ..... Circuits for electrical apparatus (*Allen*).
5779. Johnson, J. H..... Automatic holders for knives, &c. (*Berolzheimer*).
5782. Magowan, F. A., & ano. Pottery, &c.
5790. Lake, H. H. ..... Electrical conductors (*Goebel and another*).
5791. Lake, W. R..... Middlings purifiers (*Walter*).
5792. Lake, W. R..... Printing machines (*Nowell*).
5801. Anderson, J..... Cleaning seed, &c. (*Lyall & ors.*).
5807. Brydges, E. A..... Telegraph transmitters (*McCarty*).
5811. Glaser, F. C. ..... Treatment of hops (*Kempe*).
5815. Pocock, F. A., & others Regulating supply of steam, &c.
5817. Hodgkins, J..... Metallic wheels.
5819. Hoyle, G..... Card grinding machines.
5820. Fox, C. J. ..... Lowering, &c., ships' boats.
5821. Morgan, G. M..... Working of marble, &c.
5822. Clarke, W. ..... Winches.
5826. Croall, R. ..... Springs in carriages.
5827. Lardeur, G. E. ..... Transferred designs.
5832. Pouschkareff, N. L.... Lighting by means of hydrocarbon vapour.

ABSTRACTS OF BRITISH PATENT SPECIFICATIONS.

Compiled from the Published Specifications by W. E. Heys, 70, *Market-street, Manchester.*

ENGINEERING.

Compound Engines.—*A. G. Brown, Cathcart, N.B.*—In a quadruple expansion engine the inventor leads the exhaust steam from the first high pressure cylinder to the top of the second low pressure cylinder. Thence the steam goes to the bottom of the second low pressure cylinder, and then finally exhausts to the condenser or to waste. The exhaust from the top of the second high pressure cylinder acts in the same way upon the first low pressure cylinder, and thus a final exhaust is obtained, pulling in the same direction and at the same time as the piston moves in the high pressure cylinder. A convenient construction of piston is one formed of a solid bar fitting the top or high pressure cylinder, passing thence to and through the low pressure cylinder, and carrying a piston therein. A similar construction is applicable for a triple expansion, except that to produce a difference of area between the top and bottom of the low pressure piston, the rod from the bottom is considerably reduced in area, and passes through a suitable stuffing box before being attached to the connecting rod. The valves which are most satisfactory for this arrangement are of a Maltese cross section, and work in cylindrical pressure chests. They perform only a partial rotation, and are provided with a groove which momentarily opens communication between the cylinders. The inventor claims the arrangement by which the exhaust from the high pressure cylinder passes to the top of the piston in the low pressure cylinder, and thence to the bottom of the same before being finally exhausted.—No. 5135. April 6th, 1887. 8*d*.

Digitized by Google

VALVE GEAR.—*J. C. Simpson, Hull.*—The inventor dispenses with the slide valve of a steam engine, and substitutes a circular valve and a disc or plate for producing the requisite degree of expansion. The whole is operated by a rotating or oscillating movement, instead of by a sliding movement. The cylinder face on which the valve works has a port leading to each end of the cylinder in the usual way; the valve is a circular disc turning on its axis, having one port through from back to face. The steam passes to each end of the cylinder alternately through this passage as the valve is turned round. Diametrically opposite to this port is an exhaust port, which passes only through the face of the valve; the exhaust steam passes away through the interior of the valve to the low pressure cylinder. On the back of this valve is an expansion valve, working on the main valve spindle; it is connected to a speed governor by a small rod passing through a stuffing box. As the governor rises, the cut-off edge of the expansion valve meets the cut-off edge of the main valve, and cuts off the steam earlier or later automatically. Three claims are made.—No. 5588. April 16th, 1887. 8*d*.

GAS ENGINES.—*W. Bernhardt, Vienna.*—A valve held closed by a spring is inserted in the pipe leading from the slide valve box to the gas supply pipe. Between the stem of this valve and the lever which acts on it intermittently, is a movable piece, which is raised or lowered by the governor, so that when the maximum speed of the engine is exceeded the governor withdraws the movable piece from between the valve stem and the lever, and the latter no longer opens the former. This arrangement will be understood by reference to the accompanying drawings. Fig. 1 shows a side view of a gas engine, to which the present improvement is applied; and Fig. 2 shows an end view of the same. The slide C is worked in the usual way from the toothed wheel Z. The branch pipe through which the gas

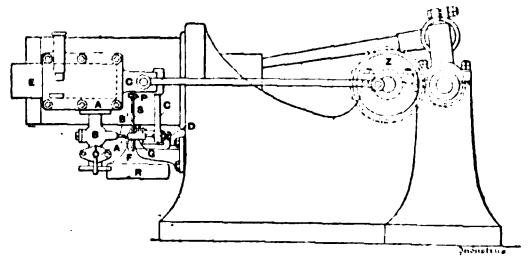

FIG. 1.

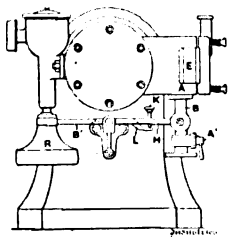
passes into the valve chest A contains a shut-off cock A^1 and a conical valve B that is held closed by a spring; the stem B^1 of B passes through a stuffing box in a direction parallel to the motion of the piston. The cock A^1 is opened when the engine is started, and is at other times closed. The slide C carries a rigid arm C^1, which has at its lower end an adjusting screw D; this screw accurately regulates the extent of the space between the valve stem B and the part connected to the slide C, which affects its inward pressure. The intermediate piece F transmits the motion of C^1 to the stem B^1, and consists of a bolt capable of sliding in a socket G. The socket G is carried by an arm H, which turns on a pivot. This pivot also carries a two-armed lever L, one of whose ends is connected to the bell R of a centrifugal governor, while the other end rests against a screw K, passing through a lateral lug on H. By means of K the bolt F can be adjusted in position between the valve stem B^1 and the adjusting screw D for any desired position of the bell R. If R



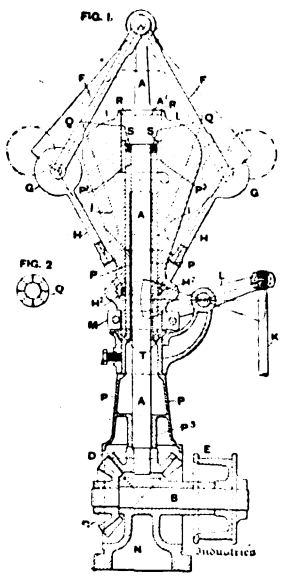


FIG. 2.

sinks below a certain position, or rises above a certain maximum, the bolt F will be correspondingly raised or lowered; consequently the valve stem B cannot be pressed back, and no gas is admitted into the slide chest. In order to start the engine, the bolt F must be lowered to the level of B^1. To effect this a catch S is pivoted to the engine frame, having its point of suspension nearer the suspension line of the engine than the socket G; when the catch hangs down free it does not interfere with the socket. When, after starting the engine, the speed for the first time rises above the normal, the socket G will be lowered and the catch S will fall back. By means of the levers L and H it is possible to arrange the engine to work with a lower minimum speed. In order to do this a weight may be attached to H, whereby the weight of R will be to some extent counterbalanced. The weight R will rise at a less speed than that at which it was originally intended to cut off the gas supply. The inventor makes six claims for the governing apparatus.—No. 5336. April 12th, 1887. 8*d*.

STEAM DRIERS AND WATER EJECTORS.—*G. G. Picking & W. Hopkins, London.*—The object for which this invention is designed is to insure the more perfect collection of the fine particles of water contained in the steam than is effected by any automatic apparatus at present employed for discharging the water of condensation from steam tubes and the like. The vessel is by preference of a cylindrical form, and is divided at its middle by a perforated diaphragm. The steam and water enter at one side of the upper part, and are directed by an internal pipe so that the stream dashes on the perforated diaphragm. The water passes through the holes and is deposited in the lower chamber. The upper division of the vessel is divided by a vertical partition; the steam which has been partly freed from its water in the first division passes through a pipe into the second division of the upper chamber. The issuing jet again impinges on the diaphragm; this further frees the steam from the particles of water that might escape the first operation, and the steam issues from the opposite side near the top of the vessel free from any water of condensation. The water collected in the lower vessel is automatically discharged by a float or cistern working on a trunnion. A valve is drawn off the end of the discharge pipe when the cistern sinks by reason of the accumulated water. When the water from the cistern is discharged through the water pipe, the cistern rises and closes the valve, which remains closed until sufficient water again accumulates. The inventors make six claims for the arrangement of the steam drier, and for the movable cistern for evacuating the accumulated water.—No. 6144. April 27th, 1887. 8*d*.

GOVERNORS.—*J. H. Street, Workington, and Tangyes, Limited, Birmingham.*—This invention relates to certain improvements in the construction of Porter's governor; the accompanying Fig. 1 illustrates such a governor containing the present improvements. A is the vertical spindle driven from the horizontal shaft B by the bevel and mitre wheels C and D; the shaft B receives its rotating motion by means of the band pulley E. The pair of links F are jointed to the upper end of the spindle A; the balls G are jointed to these links, and also to the links H which turn on the pins H^2. The weight I is suspended by the links H, and rotates with the spindle A. The rising and falling motion of the arms and weights is transmitted to the regulating valve through the rod K and lever L, which is jointed to the collar M. The driving gear C D of the governor is supported on the cast iron base N, which is surmounted by the hollow pillar P. The spindle works in bearings P^2 and P^3, which consist of portions of the hollow pillar of less diameter than the intermediate parts; the shaft A is thus only in contact with P at these bearings. The part A^2 is enlarged, and forms a shoulder which works upon and is supported by a series of washers Q. In Fig. 2 one of these washers is represented; it will be seen that radial grooves are cut in the faces in order to facilitate lubrication; the friction of the washers is reduced by distribution over a

number of working faces. The simultaneous rotation of the shaft A and the weight I is effected by the cotter R, which passes through the shoulder A^2, and whose projecting ends engage in the slots S at opposite sides of the weight I. The top of the hollow pillar is preferably higher than the centre of gravity of the weight I and the balls G. By this disposition of the centre of gravity the defect of "wobbling" is obviated to a large extent. The inventors make three claims for the arrangement of the hollow pillar, for supporting the spindle on the pillar, and for the system of anti-friction washers as described.—No. 6013. April 25th, 1887. 8*d*.

GRINDING MACHINERY.—*W. F. Goreham, Wallsend, and M. Watson, Newcastle-on-Tyne.*—This invention relates more particularly to mills for grinding cement, but it is applicable also to other mills. Instead of using ordinary stones, the inventors employ a runner and a bed constructed with discs of cast iron or steel. These discs are formed of a series of separate concentric rings, so that the greater wear of the outer portions of the face may be compensated for by means of screws. Instead of forming the grooves which constitute the faces of the runner and the bed of the ordinary depth, the inventors form radial slots through the plate. In order to prevent material escaping unground through the slots, these are cast in each disc so that they take a sloping direction from the face of the plates; the grinding edge of each thus forms an acute angle. This construction of the plates requires no further dressing, but they will continue to work efficiently until requiring renewal. Any loss in the weight of the upper disc is made up for by the addition of loose weights. Eight claims are made for the adjustably constructed bed and runner, and for the dressing consisting of slots as described.—No. 6281. April 29th, 1887. 8*d*.

TRAVERSE WARP MACHINES.—*J. Carver & J. Newton, Nottingham.*—Hitherto in imparting lateral motion to certain parts of plain net machines, viz., the comb bar, guide bars, and point bars, it has been customary to employ a separate vertical shaft fixed at one end of the machine, driven by bevel wheels from the main shaft, and provided with suitable cams and levers. The object of this invention is to arrange these levers and cams so as to insure a more dependable motion at high speeds. The usual vertical cam shaft is dispensed with entirely, and the horizontal shaft is provided with extra cams. Each of these cams is in contact with revolving trucks, in order to reduce the friction. To each end of the main driving shaft are fixed spur wheels which gear with similar wheels on separate shafts. On each spur wheel are concentric projections on the outer faces, which impart the required lateral motion to the guide bars and point bars by means of levers. These levers are provided with a truck which runs on its cam, and the other end of the lever is attached to the bar which it is to move laterally. The cam on the face of the driven wheel at the left hand end of the machine is employed to move the front guide bar; the corresponding wheel at the other end is employed for "shogging" the front point bar, while the driving wheel which is on the main shaft at the same end of the machine is employed to impart movement to the back guide bar; and the driving wheel at the left hand end moves the back point bar. The opposite ends of each of these levers have springs attached to them, in order to make them return to their normal position. The front comb bar receives its lateral motion from face cams fixed to the ordinary cam shafts. These cams impart motion to levers suitably fulcrumed to the frame; one end of each lever is provided with a truck as before. The left hand end cam is a counter to the right hand end cam, and thus the machine can be run at a greater rate than hitherto. Three claims are made for this re-arrangement of cams and levers.—No. 5970. April 25th, 1887. 8*d*.

DISC PUMPS AND BLOWERS.—*J. Bowns, Sheffield.*—The present improvements relate to that class of pumps and blowers in which a flat disc works in a cylindrical casing between two conical ends. The apparatus constructed according to this invention is represented in cross section in Fig. 1; and in

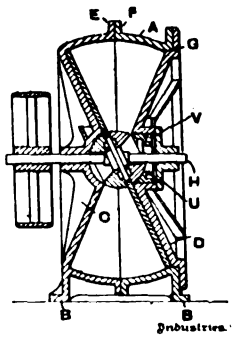

FIG. 1.

Fig. 2 an enlarged view of the disc is seen. The cylinder A rests upon the feet B; the ends of the cylinder are conical in shape, as shown in Fig. 1. One cone C is cast in the same piece with one half of the cylinder, while the other cone D is separate, and is bolted to the cylinder A by means of the flange G. The straight shaft H is supported in bearings in the conical ends of the cylinder, and on it is formed the flat disc or collar I and the bosses K L, which are inclined to the axis of H. The two hemispherical bosses M and N surround the disc I and bosses K L, and they are recessed so as to enclose and fit the disc when bolted together at O; their ends are bored sufficiently to clear the shaft H. On the edges of the two hemispheres a groove is turned, in which the large disc or piston P is secured by the bolts O. The piston P is slotted along one radius from the spherical boss to the circumference, and a partition plate is inserted therein to divide the inlet and outlet ports from one another. This partition plate holds the disc and prevents it from rotating, and when the shaft H is revolved by the pulley T the piston rolls on the cones and draws the air or liquid in alongside of the partition plate and expels it on the other side.

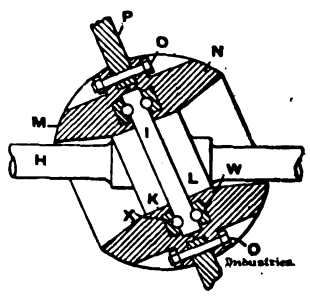

FIG. 2.

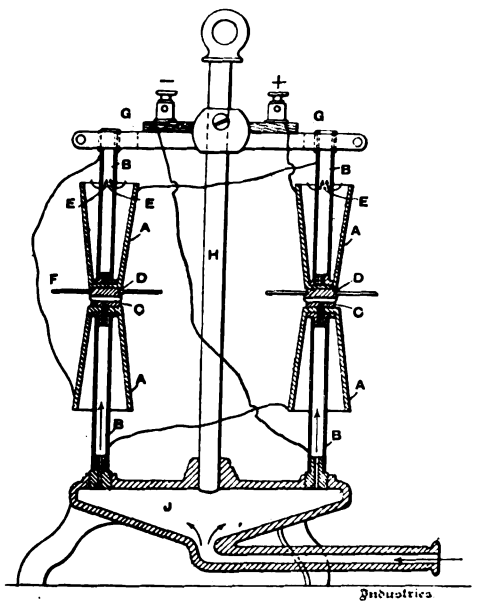
The bearings for the shaft may be cast solid with the cylinder ends, as shown on the left hand side of Fig. 1; or they may be separate and attached by bolts, as shown on the right hand side. An adjustable cylindrical bush U is inserted into one cylinder end, and is pressed by springs V against the spherical boss, in order to take up the wear. Balls are inserted between the disc I and the bosses M N, so as to form ball bearings. The hard metal rings W and X are placed in grooves in the bosses M N, and the balls run in the semi-circular grooves, as shown in Fig. 2. The cast iron or vulcanite piston is sometimes covered with india-rubber or leather, for the purpose of insuring a more perfect fit against the conical ends of the cylinder. The inventor makes three claims for the disposition of the shaft H, carrying the collar I working in the bosses M N, and for the use of ball bearings between I and M N.—No. 5794. April 21st, 1887. 8*d*.

GAS ENGINES.—*E. Casper, London.*—The object of this invention is to prevent the waste of heat which usually escapes through the exhaust, and through the walls and jacket. This object is attained by injecting water, in the form of a spray, into the cylinder at certain times between the explosions; this spray is converted into steam, which is utilised for driving the engine. This arrangement makes it possible to dispense with the water jacket. Valves and other apparatus are employed for



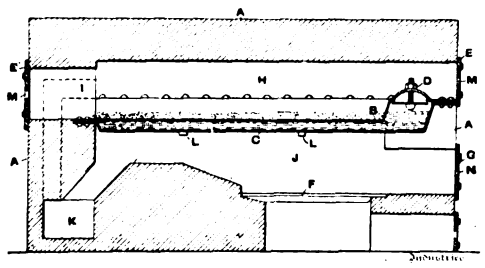
Digitized by Google

admitting the gas and for exhausting the products of combustion as usual; a valve is also arranged for admitting water under pressure from a pump, and is operated by mechanism fitted on the shaft of the engine. The piston at its innermost position is ready to draw in the explosive mixture; the explosion takes place at some time during the succeeding stroke; the return stroke causes the ejection of the spent gases. At the beginning of the next stroke a spray of water is admitted, which, when it comes in contact with the hot sides of the cylinder and piston, becomes vaporised, and yields enough expansive force to cause the next outstroke. During the return of the piston the steam is exhausted, and the admission of the explosive gas takes place again at the conclusion of the stroke. It will thus be seen that one stroke of a different character is interpolated between the two ordinary strokes of the gas engine, and the heat which is usually conducted away through the jacket is made use of in driving the engine. A saving of gas is thus effected. Three claims are made.—No. 4757. March 30th, 1887. 8*d*.

Carding Engines.—*J. H. Johnson, London. (La Société Alsacienne de Constructions Mécaniques, Belfort, France.)*—This invention relates to the adjustment of the flats of carding engines. The side frames of the engines are provided with a projecting flange, whose outer surface is truly concentric with the axis of the cylinder. A rigid adjustable segment is placed upon this flange, with its under surface corresponding exactly with the outer surface of the flange; the outer surface of the segment, however, assumes a spiral outline. The arch which forms the support of the flats rests upon this segment, and is made sufficiently flexible to enable it to accommodate itself to the varying curvatures at different parts of the segment. The piece forming the arch must be made thicker at one end than at the other, in order to keep its outer surface invariably concentric with the cylinder. By shifting the segment in a circular direction upon the fixed concentric flange, by means of a rack and pinion, the arch supporting the ends of the flats is caused to move radially towards or away from the axis of the cylinder; and when thus adjusted to the required distance, it can be secured in its position by bolts and nuts. The inventor makes two claims for the application of the eccentric segment for the purpose described.—No. 5857. April 22nd, 1887. 8*d*.

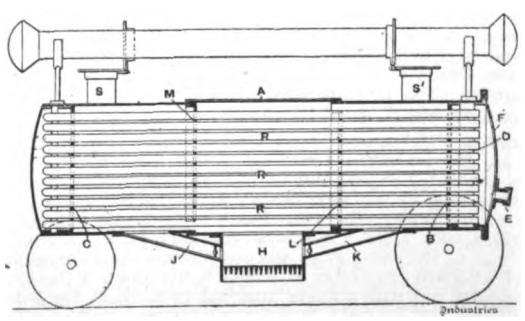
ELECTRICITY.

Thermopiles.— *R. J. Gülcher & J. Pintsch, Berlin.*— The inventors have discovered that the efficiency of the pile is increased by making the elements hollow, and so arranged that the smallest base surfaces are used for heating, while all the other surfaces are used in cooling the elements. This form of element also allows a considerable reduction in the necessary length of the bars, so that a saving is made of material, and the electric resistance is diminished. Several shapes of elements are designed, the one shown in the figure at A is made up of a hollow frustum of a cone in combination with a cylindrical element B. The action of this combined element is further increased by providing air holes E in the inner body. There is thus produced in each pair of elements a continuous circulation of air that assists in the cooling. These bodies are arranged so that they can be made to serve as their own heating apparatus. The hollow body of each pair of elements is used for the conduction of the combustible gases, and the ends of both the



hollow bodies to be heated are provided with one or more openings communicating with the inner hollow body; the gases pass through these holes and burn at the ends of the hollow bodies. This method is illustrated in the figure annexed; two pairs of elements A are placed end to end, and a plate of mica F is inserted for the protection of the upper part of A from the radiated heat of the flame. The hollow stand J is connected by a nozzle to the gas supply, and the gas passes into the several lower inner hollow bodies B; the corresponding set of upper elements are suspended from the standard H. The flat blue flame burns between the plates C and D, and at the same time heats the upper and lower pairs of elements. The electric wires are connected as shown in the figure. Seven claims are made.—No. 623. January 14th, 1888. 8*d*.

CHEMISTRY.

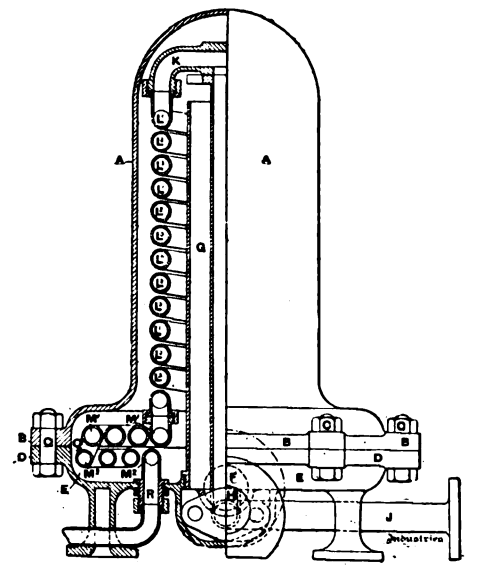


Coating Metal Plates with Tin.—*A. Gutensohn, London, and E. Cox, Datchet, Windsor.*—The present invention relates to the process of coating metal with tin by the use of grease. The plates to be tinned are cleaned by pickling with acid; they are then immersed in an organic solution obtained by pouring boiling water upon ordinary flour or other substance containing starch. Other organic substances may be substituted for starch, such as glucose and gelatine. The plates are afterwards pressed through melted grease, which is in sufficient quantity and thickness over the surface of the molten tin; the plates pass through the boiling grease directly into the tin. The preliminary treatment of the plates renders them capable of receiving the grease upon their surface at once, and the presence of the latter ensures the immediate and uniform adherence of the tin. The inventors make one claim for the use of the solution containing starch or glucose capable of combining with the greasy matters.—No. 4846. March 31st, 1887. 6*d*.

Extraction of Gold from its Ores.—*J. Weirich, Béziers, France.*—This invention provides a new process for abstracting the sulphur from the ore before submitting it to the mercury process. The pulverised mineral is heated in the presence of a feeble current of air to a temperature of 400°C.; the gold is freed and the sulphur is partly eliminated by volatilisation. The figure represents a vertical longitudinal section of the apparatus constructed for the purpose of carrying out this invention. The arrangement consists essentially of a furnace of ordinary construction, whose interior is divided horizontally into two distinct chambers H and J, by two pans of strong sheet iron B C. These pans are riveted together all round their edges; near the front end of the upper chamber the pan B is pierced with an opening

D, fitted with a tight cover. The outer end of the coupled pan rests on a shoulder within the furnace, and for greater security the lower pan rests on bars L. The upper pan receives the pyrites to be treated, which is introduced through E¹ and spread out in a layer. The pans are made at the hinder end with no projection above the upper pan B, to facilitate the charging and discharging of the furnace. The lower pan C receives the lead, which forms a bath for heating the pan B. The lead is introduced in a molten state through D. Under the influence of the fire in F, the lead is kept at a temperature of 350°—400°C. The fire at F is fed with fuel through a door G; air enters through the perforation N, and also underneath the fire bars. The products of combustion leave for the chimney through the flue K. The desulphurising current of air is admitted through the perforation M in the door E, and is drawn by the current of air in the chimney over the surface of the ore, and down the channel I into the flue. The inventor makes two claims for thus eliminating the sulphur without ignition.—No. 7657. May 26th, 1888. 7*d*.

Production of Hydrogen.—*W. Majert & G. Richter, Grünau, Germany.*—The object of this invention is to produce hydrogen gas for military purposes. The principle on which it is based is that finely divided zinc, when brought in contact with water and heated, becomes oxidised and releases the hydrogen from the water. Cartridges are made of zinc dust and dry hydrated lime or magnesia, or doubly hydrated chloride of calcium, enclosed in a yielding case of sheet iron, about 20cm. in diameter and 70 cm. long. The accompanying illustration shows a section of a convenient apparatus for carrying out the object of this invention. A number of tubes R are fitted into the ends B and C of the retort A. The tubes may be open at both ends, or they may be open at one end as shown; their ends project into a chamber D, which is closed by a cover F; an outlet pipe is provided at E. The tubes R are closely fitted in the tube plate B, so that the space D is quite shut off from the other part of the retort. The heat from the furnace H passes into the vessel A and circulates around the tubes R; baffle plates L and M are arranged so as to retain the heat in the retort. The tubes J and K, with suitable throttle valves, pass from the furnace to the retort in order to permit the heat to circulate



quickly, and the chimneys S and S¹ serve to carry off the products of combustion. In using the apparatus, the tubes R, after the cover F has been opened, are filled with the cartridges specially prepared, and then the cover F is closed. The heat of the furnace is now applied; the soldering of the cartridges melts, and the hydrogen is liberated and collects in the chamber D, from whence it is led off through the outlet E. The whole apparatus is mounted on wheels, and the chimneys are hinged, in order to facilitate its carriage in the field. Four claims are made for the method of preparing the hydrogen, for the construction of the cartridges, and for the apparatus as described.—No. 4881. April 1st, 1887. 8*d*.

Extraction of Gold from Ores.—*A. Woodhouse, London.*—This process relates to the method of amalgamating the gold contained in the ores without mechanical agitation. The ore is first to be crushed to a fine powder by a usual pulveriser, and the crushed products, after admixture with mercury, are washed by a suitable stream of water, in order to insure their uniform delivery into a canister provided with a perforated bottom. The ore is then delivered upon a dropping amalgamator or a silver-plated copper table. The ore is then discharged over the usual ripples and corrugated plates. In an amalgamating box a series of check plates are provided, which consist of vertical plates placed transversely to the flow of the amalgamated ore; orifices with side projecting wings are so arranged as to flank each other in the successive check gates The inventor claims: (1) The combination of a pulveriser, perforated distributor, inclined amalgamating plates and ripples, with an amalgamating box; and (2) the construction of the amalgamating box, consisting of a series of vertical plates placed transversely to the flow, and provided with the orifices as described.—No. 5627. April 18th, 1887. 8*d*.

MISCELLANEOUS.

Sea Water Distillers.—*G. Gravely, London.*—The improvement in condensers for sea water distillers, included in this invention, enable the condenser to be easily opened for examination. The sea water discharge pipe is connected with the base of the apparatus, the steam pipe is carried through the sea water discharge pipe, and spiral condensing coils are combined with volute refrigerating coils. The construction of the condenser is shown in section and elevation in the annexed figure. The shell A is formed at the bottom with a flange B, which is connected by the bolts C to a corresponding flange on the base E. The sea water pipe F is connected to the base E at one side; by its means the whole of the shell is kept filled with sea water. The sea water discharge pipe G is placed vertically in the centre of the condenser, extending from the base upwards; at its lower end it communicates with an outlet H. The steam pipe J enters the

outlet H and passes up through the centre of the discharge pipe G; when it emerges from the discharge pipe it divides into three branches K, which communicate respectively with the three condensing coils L^1 L^2 L^3. The inmost turn of the first refrigerating coil M^1 has three sockets, which respectively receive the lower ends of the three coils L^1 L^2 L^3. The second volute refrigerating coil M^2 is connected at Q in its outermost turn with the same turn of M^1. The fresh water discharge pipe R is connected to the inmost turn of the coil M^2. It will be seen that all the inlets and outlets are at the base at the apparatus, and are below the line of connection of the shell A and the base E; hence, by merely unscrewing the bolts C, the shell can be lifted off without disconnecting any pipes or valves. The inventor makes five claims for the disposition of the various coils as described and shown in the drawing.—No. 5841. April 21st, 1887. 8*d*.

Preparation of Gelatinised Grain.—*J. Death & A. S. Tomkins, London.*—This invention relates to the preparation of gelatinised grain, such as is frequently used in brewing, distilling, and vinegar making, and its object is to obviate the disadvantages attendant on the passage of the steam through the grain. The grain is to be first moistened, and then heated in the usual way by means of a current of hot air. Into the moist grain thus heated is passed a current of steam at atmospheric pressure until gelatinisation is effected. The steam may be superheated, and it may be passed into the hot moist grain either continuously or intermittently, and may be alternated with currents of hot moist air. One claim is made.—No. 12188. September 8th, 1887. 4*d*.

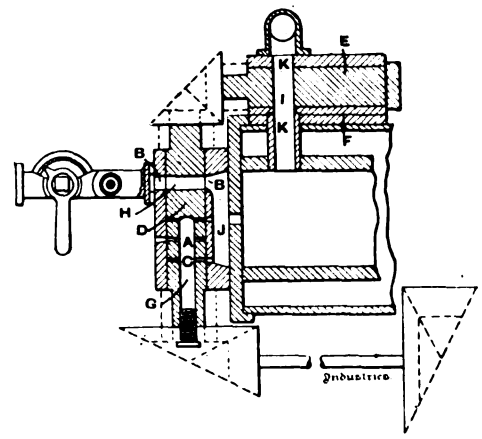
Fulling and Washing Machines.—*E. Kempe, Leeds.*—The object of this invention is to improve the construction of combined fulling and washing machines, in which the fabrics are treated while in a rope form. The ropes of cloth are passed between a pair of fulling bowls or rollers, which are pressed together by springs; one of the rollers is provided with deep end flanges, to prevent the rope of fabric from escaping from between the rollers at their ends. According to this invention, all the rollers are made of compressed cloth formed by threading numerous discs of cloth side by side on to a metal bar adapted to serve as an axis of the roller, and then compressing the assemblage of discs by means of a powerful press. The machine may not only be provided with a pair of fulling rollers, but also with other rollers for washing the fabric if desired. Two claims are made.—No. 5961. April 23rd, 1887. 6*d*.

Digitized by Google

POLISHING AND LACQUERING TUBES AND BARS.—*R. J. Edwards and A. Edwards, London.*—In constructing apparatus for grinding and polishing tubes and bars, the inventors arrange two rotating discs face to face, mounted on separate spindles. The opposing faces of the discs are prepared with a soft material such as felt; one or more strips are attached to the face of the disc by glue or cement, in a spiral form, leaving a narrow space between each succeeding coil. The opposite faces of the discs are not to be exactly parallel, but one of them is arranged so that its revolving face is vertical, whilst the other is inclined more or less, so that while its lower edge nearly touches the first disc, their upper edges may be separated, and thus leave an angular space between them. The bearings supporting the spindles are made adjustable, so that they may revolve at any required distance apart. One of the shafts is made hollow, and the abrasive powder is fed through it. The whole apparatus is inclosed in a case, and the tube to be polished is inserted through a hole in the side of the case, in order to be operated on between the two discs. In lacquering the tube, the inventors use an annular brush of felt, through which the tube passes as it leaves the discs. The brush is fitted into a hollow chamber, whose lower part contains a supply of varnish at a suitable temperature, and the entire device is passed rapidly along the tube while the brush is rotated. Five claims are made.—No. 2558. February 18th, 1887. 8*d.*

TIN BOXES.—*G. F. Griffin, London.*—These tins are constructed in such a manner that they shall offer no obstruction to the extraction of the contents, and that the cover shall be removable by a lever. The body is made in one piece, from one end of which a circular piece is cut. The flange which is thus left is folded inwards; the top of the fold is pressed outwards to form an annular recess, and the edge acts as a fulcrum for the raising lever. The bottom of the fold serves as a clip or spring against the lower part of the neck of the lid when in position; and the opposite end of the body is fitted with a bottom in the usual way. There are several modifications described in the specification; but the above is the one preferred by the inventor. Four claims are made for the various forms.—No. 6232. April 28th, 1887. 8*d.*

BORING AND DRILLING MACHINES.—*T. Bower, R. W. Bower, J. Blackburn, Woodlesford, & F. Mori, Leeds.*—These improvements relate to the employment of an electromotor for imparting motion to machines for boring, drilling, and under-cutting minerals. For this purpose a dynamo of high tension is used, from which the electromotive force is transmitted through cables to a motor attached to the boring machine. When used for drilling or boring only, any required number of spindles may be employed, and the motor connected by suitable gearing so as to bring all the tools into simultaneous operation. A cut-off motion is placed between the motor and in connection with the cables, in order to regulate the speed of the motor. Two claims are made for the application of the electromotor for the purposes of imparting motion to the rock drill.—No. 7662. May 26th, 1887. 8*d.*

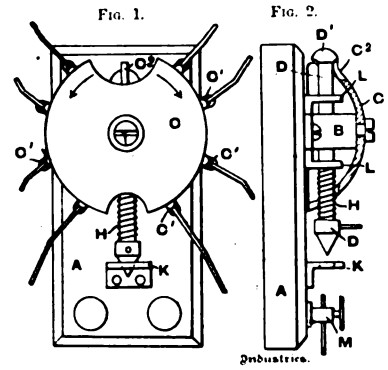


SELF ADJUSTING DIE FOR SCREW MAKING MACHINES.—*C. D. Rogers, Providence, Rhode Island, U.S.A.*—The present invention relates to machines for automatically forming the threads of wooden screws, and introduces an improvement into the adjustment of various parts, and an automatic accommodation to each other of the thread forming dies. The stationary die is secured in a holder which is both laterally and longitudinally adjustable. The holder has an elastic support which maintains the die in its normal relation to the travelling die, and permits a slight downward movement of the holder against the resistance of the spring. If this movement is exceeded a fixed stop prevents further action of the die in this direction; an adjustable stop is also provided for limiting the upward motion of the holder. The extreme vertical movement of the holder need not ordinarily exceed one thirty-second of an inch. This small up and down movement of the holder, while rolling the threads, is produced by the slight inequalities of the dies, which for the instant do not always exactly register. By means of this arrangement the automatic adjustment of the die is made possible. Three claims are made for the automatic adjustment described.—No. 17831. December 28th, 1887. 8*d.*

SOFTENING AND PURIFYING WATER.—*G. E. Davis, Manchester.*—In order to remove the lime out of well water, the inventor employs the tribasic phosphate of soda for effecting the precipitation of the lime salts. The residue left at the bottom of the water may be used as manure, as it contains a large quantity of phosphate of lime. The inventor claims the use of phosphate of soda in softening water.—No. 5655. April 19th, 1887. 4*d.*

MANUFACTURE OF ROPE FOR HARVESTERS.—*W. M. Cranston, London. (The Walter A. Wood Mowing and Reaping Machine Company, Hoosick Falls, New York.)*—This apparatus is attached to a harvester, and is adapted for the making of rope used for tying bundles of grain while the machine is at work in the field. A cradle is provided for this purpose, in which straws of a given length are inserted. A disc in the lower end of the cradle has a reciprocating circular motion imparted to it by a crank and bar. The bar carries a blade, which passes through the side of the cradle and knocks the straws up to prevent them from matting. The disc is intended to keep the butt end of the straws in position. Entering into the slot in the bottom of the cradle is a toothed picker wheel, to which rotary motion is given; the teeth take straws in succession and put them in the path of a pusher. The picker wheel is in frictional contact with a spring which pushes it round. When the straws arrive against a dog plate, the pusher feeds them through an opening in one side of a drum, which carries a hook for laying the straws between a pair of rollers. These rollers in rotating draw the straws in between them, and press them against a cup shaped piece of the outer plate, which turns the straws through a right angle. The drum is mounted on a frame, and its rotation gives the twist to the straws while partially within the drum; the twist is completed between the drum and the outside pair of draw rollers. The twisted straws are then led off and wound on a reeling mechanism. After each motion forward of the toothed picker wheel, the wheel has a backward motion imparted to it by a pawl; each tooth in succession thus clears itself and prevents entanglement. As each bundle is bound, the fall over of a lever stops the twisting mechanism; but as soon as sufficient straws are gathered to form a fresh bundle, the lever is moved back again. This motion acting upon a clutch causes the twisting mechanism to be thrown into gear again. Four claims are made for the parts, as described.—No. 6352. April 30th, 1887. 8*d.*

GERMAN PATENT ABSTRACTS.



GAS ENGINES.—*C. G. Schranze, Riesa-a-d-Elbe.*—The valve D, which is revolved by means of bevel wheels in proportion of 4 to 1 to the crank shaft, is provided with perforations H corresponding to openings in B in the valve casing J for admitting the mixture of gas and air. D is also fitted with a cylindrical

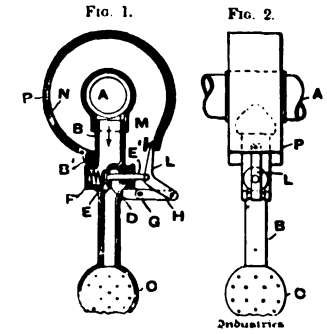
recess G having the perforations A and C. In G the flame for igniting the gas burns, the ignition taking place through A and C. D actuates the valve E through the openings I and K, of which the exhaust is effected.—No. 42530. August 14th, 1887.

ALARUM APPARATUS.—*E. Bettelheim, Milan.*—The bell C, which turns freely on a pivot B secured to the plate A, is provided with loops into which strings are secured. These strings are provided with hooks, by means of which the apparatus may be secured to a net spread before the window or door to be secured against burglarious attempts. A metallic bolt D, provided with a head D, slides freely in the guide L. When putting the appara-

FIG. 1. FIG. 2.

tus up this bolt is secured by a small hook C_2, which is fastened to the bell C. As soon as somebody touches the net, C_2 becomes disengaged and the bolt D is forced by the spring H against the contact K, thereby establishing an electric circuit in an alarum bell, one wire of which is clamped to K, the other one being fastened at M.—No. 42504. May 27th, 1887.

UNITED STATES PATENT ABSTRACTS.



SPIRAL GIRDER.—*W. W. Green, Chicago.*—The girder which is the subject of this invention consists mainly of a helicoidal sheet of metal. Four tie rods extend from breast plate to breast plate, and penetrate each successive helix of the girder. Between each helix, and surrounding the tie rods, are compression bars, and a series of rods or cables extend from breast plate to breast plate, passing diagonally between each coil of the girder. The inventor makes two claims for this form of girder.—No. 379217, dated 13th March, 1888.

LET-OFF MECHANISM FOR LOOMS.—*H. Litchfield, North Adams, Massachusetts.*—According to this invention a shoe or yoke is pivoted at one end to the loom frame, and encircles a pulley geared to the warp beam. At its free end on the other side of the pulley, the yoke has a weight attached and is provided with a slot. A flexible friction strap is also fixed to this end of the yoke, from whence it passes round the pulley, and is attached at its other extremity to the frame of the loom. A weighted rod, with a finger attached to work in the before mentioned slot, regulates the pressure of the belt on the pulley, and thus controls the speed of the letting-off mechanism. One claim is made for this apparatus regulating let-off mechanisms.—No. 379173, dated 6th March, 1888.

STEAM BOILER.—*A. Catchpole, Geneva, New York.*—This invention relates to that class of steam boilers in which the water and steam is contained in tubes exposed to the direct action of the flames. The outer shell of the boiler and of the furnace below it is made of cylindrical form. Inside the exterior shell are two series of annular concentric tubes, which communicate with one another alternately. Above these tubes is one large tube, at the outside of which is a flange. This tube rests on the top of the outer casing by means of the flange, and is riveted down in position by rods which pass vertically through all the tubes. An annular casing surrounds the furnace in which the fuel burns, and the water contained in it communicates with that in the tubes. This water is exposed to the direct influence of the fire, while the water and steam in the tubes are superheated by the products of combustion circulating between the tubes. The connections made between the different sets of pipes and the vessel surrounding the fire insures a constant circulation of the water, while the steam collects in a heated condition in the uppermost tube ready for use. Three claims are made.—No. 379048, dated 6th March, 1888.

FIRE EXTINGUISHER.—*W. G. Brown, Atlanta, Georgia.*—The accompanying illustrations represent a cross section and a side elevation of the fire extinguisher here described. The main water supply pipe is shown at A, and the branch pipe B is coupled to it in the manner represented in the diagram. The valve E is pressed against its seat by the spring F, and ordinarily prevents the passage of water to the sprinkling rose C. A compound plate of metal P N is pivoted at B to B^1, and its other end is loosely connected to the lever L by the screw M; the link H is pivoted to the fixed projection G and to the lever L;

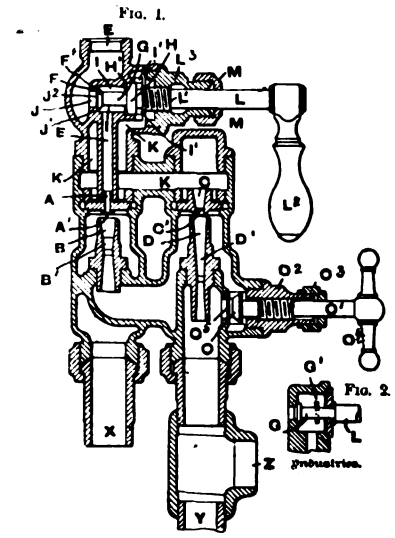


FIG. 1. FIG. 2.

the stem of the valve E passes through a stuffing box and presses against a hollow in the elbow of L. The plate P N is made of two different metals, the outer one of which expands more by heat than the inner one. The result is that when there is a fire in the neighbourhood of this apparatus, the plate presses the elbow lever L towards the pipe B, and so opens the valve E against the pressure of the spring F; the water thus gains access to the sprinkler and escapes through the perforations. One claim is made for this method of automatically operating the sprinkler.—No. 378285, dated 21st February, 1888.

INJECTOR.—*C. E. Randall, Boston, Massachusetts.*—The accompanying section of the injector indicates the improvements in the arrangement of the steam inlet valve. The steam enters at E, the suction is at X, and the delivery at Z, while Y represents the overflow pipe. The steam port J communicates with the passage I, into which enters the lifter steam jet tube E^1, and the ports I^1 allow the steam to pass into the forcer steam jet tube K

FIG. 1.

The two valves F^1 and H controlling the entering steam are mounted on the same spindle L, to which is attached the operating handle L^2. The valve H is adapted to close the ports I^1, and to keep them closed until the valve F^1 is moved sufficiently to open the port J, and to unclose them upon further movement of the valves. Five claims are made for this disposition of the steam inlet valve. No. 378403, dated 21st February, 1888.

The full specifications of the British and United States patents, and the Official Journals of the German Patent Office, from which the above abstracts have been compiled, and the Official Journal of the United States Patent Office, may be seen by subscribers and clients at the Reading Room, Manchester Office of INDUSTRIES, *where also Patent Indexes from* A.D. 1617 *may be consulted. Copies of the British specifications may be obtained on application to* H. READER LACK, ESQ., *Comptroller-General, Patent Office, Southampton Buildings, London, W.C. The published price must be remitted, together with a sum sufficient to cover postage, which may be reckoned at ½d. for every 10d. or fraction of 10d. Remittances exceeding one shilling must be made by Post Office Order.*

INSTITUTION OF NAVAL ARCHITECTS.

(Concluded from page 340.)

THE proceedings on Friday morning, the 23rd March, opened with the reading of a paper by Mr. R. E. Froude, on

THE CONSTANT SYSTEM OF NOTATION OF RESULTS OF EXPERIMENTS ON MODELS USED AT THE ADMIRALTY EXPERIMENT WORKS.

At the Admiralty Experiment Works the resistance of models is ascertained for a variety of speeds, and generally for three different draughts and fore and aft trims. The results obtained in the past with miscellaneous models may be valuable for the future, provided the information is presented in a form under which the performances, proportions, and, as far as possible, the characteristics of shape become directly comparable. For this purpose the author has adopted a system of notation, according to which the proportions and, to some extent, the lines of the hull are characterised by numerical values, representing measurements in terms of a unit dimension proportional to the cube root of the displacement. Thus, for instance, if the displacement be given in cubic feet, the unit dimensions to which all linear measurements are referred would be the side of a cube containing as many cubic feet as the immersed part of the hull. The performance is characterised by two so-called constants K and C, the former denoting speed in terms of a unit speed proportional to the sixth root of the displacement, and the latter the corresponding resistance in the form of the reciprocal of what is known as the Admiralty displacement constant, viz., the horse power divided by the product of the third power of the speed V and the two thirds power of the displacement Δ. The object of the author was to express the constants K and C in such a way that their values should be indeed constant for similar forms at corresponding speeds, whatever the absolute size, and for this purpose he has eliminated the influence of size by the adoption of the relative unit of length, as above mentioned. In other words, he aimed at showing for any particular hull by a variety of curves the value of C as dependent on the value of K. The author exhibited these curves in some wall diagrams. The value of K must be proportional to $\frac{V}{\Delta^{\frac{1}{3}}}$, and for C the author introduces the formula $C=\frac{R}{\Delta K^2}$, which by substituting K becomes $C=\frac{R}{\Delta^{\frac{1}{3}} V^2}$. Since the product of resistance and speed is proportional to effective horse power, the above formula agrees with the Admiralty displacement constant already mentioned. We have $C=\frac{E.h.p.}{\Delta^{\frac{1}{3}} V^3}$. The hull dimensions are expressed in a unit $U=\Delta^{\frac{1}{3}}$ and K expresses the ratio of the speed to a unit or standard speed appropriate to the displacement and proportional to its sixth root; in other words, to a wave having a length proportional to U. For convenience, the author has chosen 2U as the length of a wave, the corresponding speed of which makes K equal to unity, so that $K=\frac{V}{\Delta^{\frac{1}{6}}}\sqrt{\frac{1}{4\pi g}}$; and, thus defined, K becomes unity for a vessel of about 5000 tons at a speed of seven knots. Since the resistance for this value of K is generally rather less than $\frac{1}{1000}$th of the displacement, the author finds it convenient to avoid decimals by writing $C=\frac{1000\,R}{\Delta K^2}$. In order to account for skin friction and influence of length, the author introduces a skin constant which is the wetted area divided by U^2, and a length constant which is the length between perpendiculars divided by U; but the space at our disposal does not permit of our noticing in detail the various connections which he applies to the formulæ by means of these co-efficients. We have only given here a short outline of the author's methods, to show that rational systems of measurement, which in other branches of applied science have been adopted with so much advantage, are now also used in naval architecture.

The discussion was opened by

Mr. Benjamin, who remarked that, in estimating resistance, designers have to use a number of so-called constants which are really not constants, but are left to each designer to settle for himself. The speaker was glad that Mr. Froude had nearly abolished these "variable constants." The resistance had been divided into two parts—first, that not relating to friction; and, secondly, that relating to friction. The former is dependent on the size, speed, and shape of the vessel; the latter mainly on wetted area. It does not depend on the same factors of the vessel as C and K, and the speaker believed skin friction to be much more conjectural than Mr. Froude assumes.

Mr. White expressed his indebtedness to Mr. Froude for the valuable assistance he had often rendered him in matters that went beyond experiment. He hoped that shipowners, especially their friends in Dumbarton and Italy, would plot their records of ship trials as Mr. Froude had done.

Mr. Inglis regretted that shipowners had so few facilities for these experiments. Most shipbuilders try their vessels systematically, using the actual dimensions and the cube root of the displacement as the basis of comparison. He wished they could elucidate certain points by model experiments, but only one tank was held by a private owner. He suggested the erection of a co-operative tank.

Mr. Froude, in reply, said that he had written the paper hoping to induce other workers with either models or full ships to adopt his notation, as it would be a great advantage to have only one system in use.

The next paper read was by Professor A. G. Greenhill, on

A THEORY OF THE SCREW PROPELLER.

In this paper the author gave a new method of calculating the thrust and efficiency of a screw propeller, different in some respects from the methods employed by Rankine, Froude, and Cotterill. In the discussion on Professor Rankine's paper in 1865, Mr. Charles Lamport drew attention to the angular effect of the propeller upon the water, and in his reply Professor Rankine maintained that the loss of work (simply proportional to the slip of the propeller) comprehends the effects of rotating or transverse as well as of backward slip. In the papers of Rankine, Froude, and Cotterill the propulsive thrust is first calculated from the backward motion imparted to the water, and then the turning couple on the propeller is found. In the present paper the order of these operations is reversed; the turning couple L of the propeller is first calculated from the angular momentum imparted to the wake, and then the thrust T is calculated from the formula $Tp=2\pi L$, where p denotes the pitch of the propeller. Fluid friction, wake action, blade displacement, &c., are here left out of account; but the consideration of these disturbing causes, which tend to mask the main principles in question, is taken up in a subsequent part of the paper.

Suppose the wake to leave the propeller with axial velocity v, and let n denote the revolutions of the propeller, then $n-\frac{v}{p}$ is the rotary speed of the wake, and the angular momentum communicated to the wake is

$$L=\frac{w}{g}\left(A^2-B^2\right)v\left(n-\frac{v}{p}\right)$$

when A denotes the disc area of the propeller, B the cross sectional area of the boss, and w the weight in pounds of a cubic foot of water; v is assumed uniform throughout the wake.

Since $B^2 : A^2$ is small in practice it may be neglected; and the thrust given as

$$T=2\pi\frac{w}{g}A^2\frac{v}{p}\left(n-\frac{v}{p}\right)$$

If u denotes the velocity of feed of the propeller, which, neglecting wake action, will be the same as the speed of the vessel, then $np-u$ is the slip velocity of the screw; and the slip ratio $s=(np-u)\div np$.

The efficiency e of the propeller is the ratio of work done by the thrust to the work consumed in turning the propeller; so that

$$e=\frac{Tu}{2\pi Ln}=\frac{u}{np}=1-s.$$

Since for similar screws with given slip ratio s at speed u, the thrust varies as $A^2\div p^2$, that is as A or p^2, it follows that the disc area of a single screw should be double the disc area of each of two similar twin screws required to drive the same vessel at the same speed. The weight of a single screw will thus be $V2 = 1{\cdot}4$ times the weight of the two twin screws, but the revolutions of the twin screws must be V2 times that of the single screw. The reduction of weight in the twin screw system is of great practical advantage in very long vessels, when pitching comes into play. The loss of energy at the rate of foot-pounds per second is

$$2\pi Ln-Tu=2\pi\frac{w}{g}A^2u\left(n-\frac{u}{p}\right)^2$$

half of which represents the energy being communicated to the revolving motion of the wake, the other half being the loss of energy due to the shock of the impulse of the water on blades of uniform pitch. It is impossible to suppress entirely the first loss due to the churning action of the propeller, because it is from this churning action that the thrust of the propeller arises. The second loss of energy may be suppressed by Mr. Bennet Woodcroft's screw of gaining pitch; and then the effective pitch of the propeller is the harmonic mean of the initial pitch $u\div n$ and the final pitch p.

The value of the turning couple is the same as before, $L=\frac{w}{g}A^2u\left(n-\frac{u}{p}\right)$, but thrust is now $T=\pi\frac{w}{g}A^2\left(n^2-\frac{u^2}{p^2}\right)$ In the analogous case of a feathering paddle wheel the plane of a blade on entering the water should be perpendicular to the plane passing through the lower edge of the blade and through the lowest point of the apparent rolling circle, in order that the blade should enter the water edgeways without shock. In order that a blade should leave the water without shock the plane of the blade should be perpendicular to the line joining it with the lowest point of the pitch circle; that is, the plane of the blade should pass through the highest point of the pitch circle. In practice the second only of these requirements is attended to, while the first is disregarded, although of equal practical importance, and attention to it would secure a notable increase of speed in the new Channel packets.

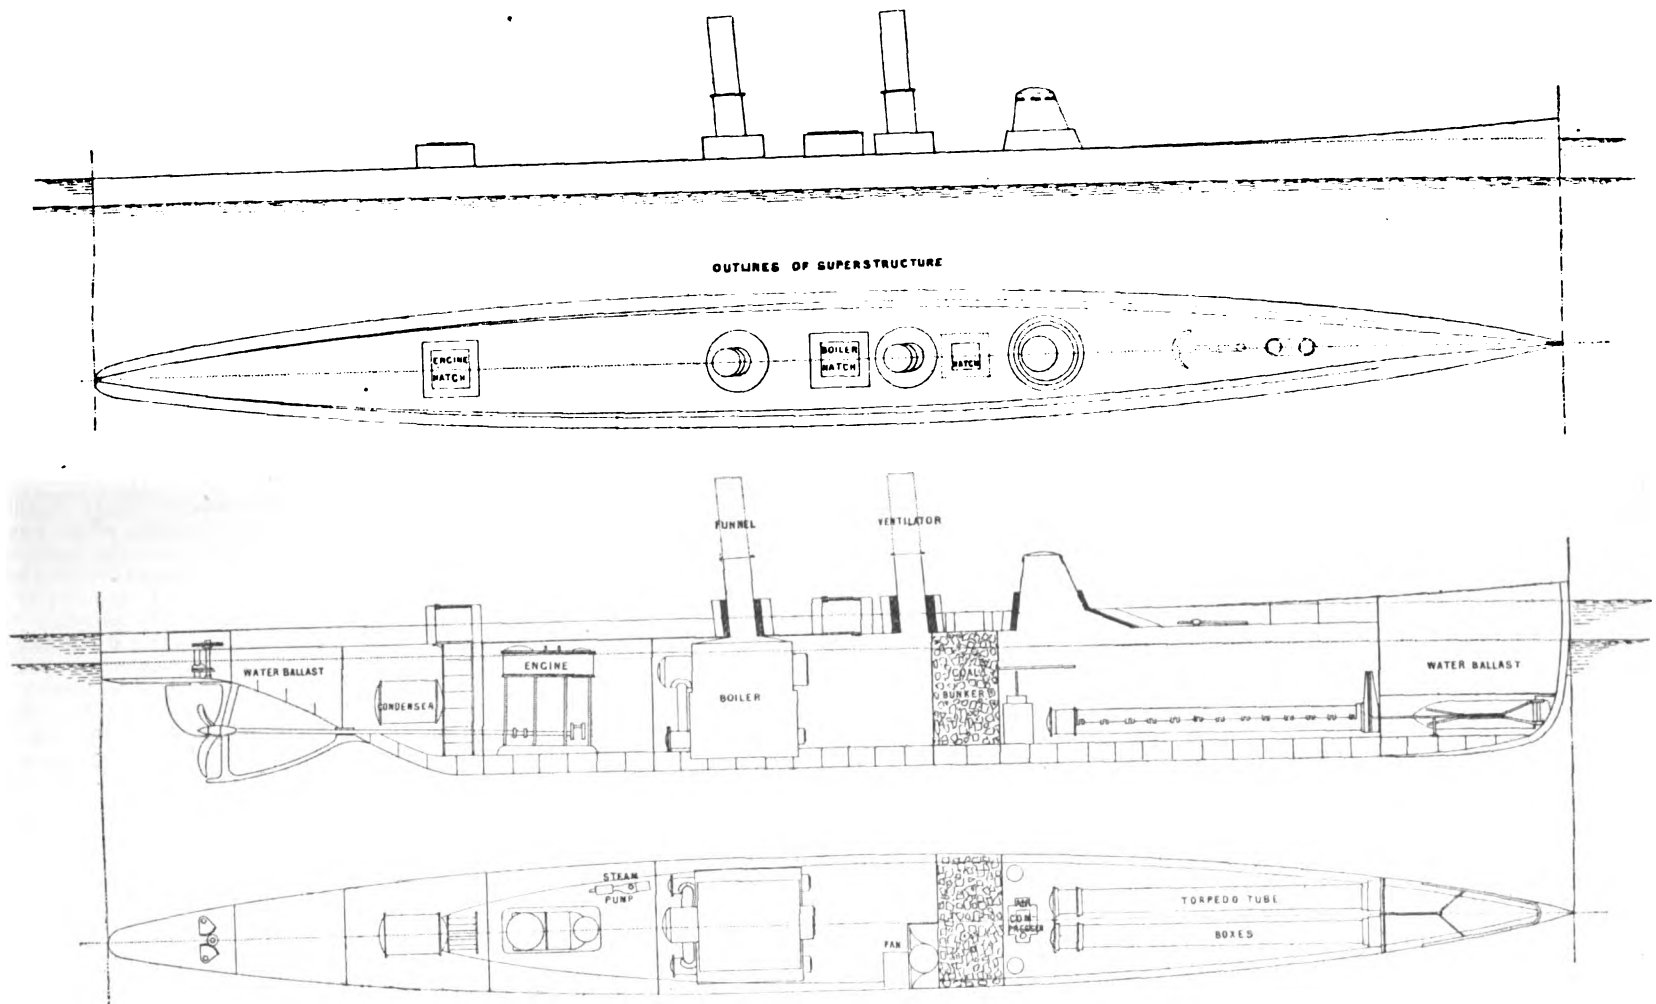
The author next considered the case of double screws, with special reference to the Whitehead torpedo, and found that no gain in efficiency is obtained by double screws of uniform pitch, the loss by shock at the second screw counterbalancing the gain of energy from the rotation of the wake of the first screw; but if the screws are made of increasing pitch there is no loss of energy by shock, and an increase of total thrust. Referring to guide blade propellers, the author thought that the small gain of efficiency and the large weight of the guides will prevent their adoption for use at sea. The stern post and rudder in an ordinary single propeller may be considered to act as a single guide blade of infinite pitch; but this contributes nothing to the propulsion of the vessel, while it has the disadvantage of transmitting vibrations to the hull. Next followed investigations on the effect of fluid friction, and on the pressure in the propeller wake. Regarding the latter, the author pointed out that the pressure increases towards the circumference, and that therefore the propeller tends to draw water forward near the axis, with the result of diminishing the effective thrust, and discharge it backwards at the tips. He recommends that propellers should be so designed as to increase the pressure in the wake towards the centre, which can be effected by diminishing the pitch towards the circumference, and by shaving off the tips of the blades to a point.

The discussion which followed was short and devoid of special interest.

The next paper read was a communication by Mr. J. B. Andreæ, on

EXPERIMENTS WITH FOUR AND TWO BLADED SCREW PROPELLERS.

Three series of experiments were made last year on the "Ceram" and "Flores," two vessels built for the Dutch Indian Navy. The first was with a four bladed screw of 9ft. diam., 13ft. pitch, and 30 sq. ft. blade surface; the second with the same screw, but with the two opposite blades removed; the third with a two bladed propeller of the same diameter, but 11ft. 8in. pitch, and 17 sq. ft. surface. The vessels each measure 152ft. in length, 25ft. 7in. in width, and 15ft. 5in. in depth. The displacement is 566 tons, the immersed midship area is 189 sq. ft., and the wetted surface of the coppered skin 4875 sq. ft. The engines are triple compound, with cylinders, in the "Ceram," of 20in., 29in., and 46in., and in the "Flores" of 20in., 28in., and 46in. diam., the stroke in both being 27in. The boilers are double ended, work at 120lb. pressure, have 65 sq. ft. grate, and 2000 sq. ft. heating surface; they are fitted with forced draught, and the "Ceram" has a closed stoke hold. The vessels are practically the same, and the trials were made under the same conditions of weather and sea. The author presented curves which showed that in the case of the "Ceram" the removal of two of the blades only resulted in a slight increase in the number of revolutions, so that the loss of one half of the propelling surface was more than balanced by the gain in friction and other causes. At a speed above 12 knots the vibrations of the two bladed screw of the "Ceram" became troublesome; but this was less noticeable in the "Flores," the propeller of which had less pitch and more surface. From the curves of revolutions and i.h.p. shown by the author, he has composed the following table, showing the i.h.p. by regular intervals, wanted for a certain number of revolutions with the four bladed and the two bladed screw of the "Ceram:"—



1. Revolutions	80 ...	90 ...	100 ...	108 ...	116 ...	123 ...	128
2. I.H.P. four bladed propeller	200 ...	300 ...	400 ...	500 ...	600 ...	700 ...	800
3. I.H.P. two bladed propeller	140 ...	210 ...	300 ...	375 ...	465 ...	545 ...	625
4. Difference between 2 and 3.....	60 ...	90 ...	100 ...	125 ...	135 ...	155 ...	175
5. Difference in percentage of 2.....	30 ...	30 ...	25 ...	25 ...	22 ...	22 ...	22

From the curves of speed and i.h.p. the following table has been deduced, showing the i.h.p. by regular intervals, wanted for a certain speed of the "Ceram" with the four bladed and the two bladed screw:—

1. Speed in knots.....	8·7 ...	9·7 ...	10·6 ...	11·35 ...	12
2. I.H.P. four bladed propeller.	200 ...	300 ...	400 ...	500 ...	600
3. I.H.P. two bladed propeller.	180 ...	275 ...	375 ...	480 ...	625
4. Difference between 2 and 3.	20 ...	25 ...	25 ...	20 ...	25
5. Difference in percentage of 2.	10 ...	8 ...	6 ...	4 ...	4

INSTITUTION OF NAVAL ARCHITECTS.

Principal Dimensions

Length overall	78′	Breath ext.	7′
Maximum Displ^t	63 tons	Smallest Displ^t	57 tons
Draught of Water	8′	Draught of Water	forw. 6′ 7″ aft. 6′ 7″
Speed	13 knots	Speed	13 knots

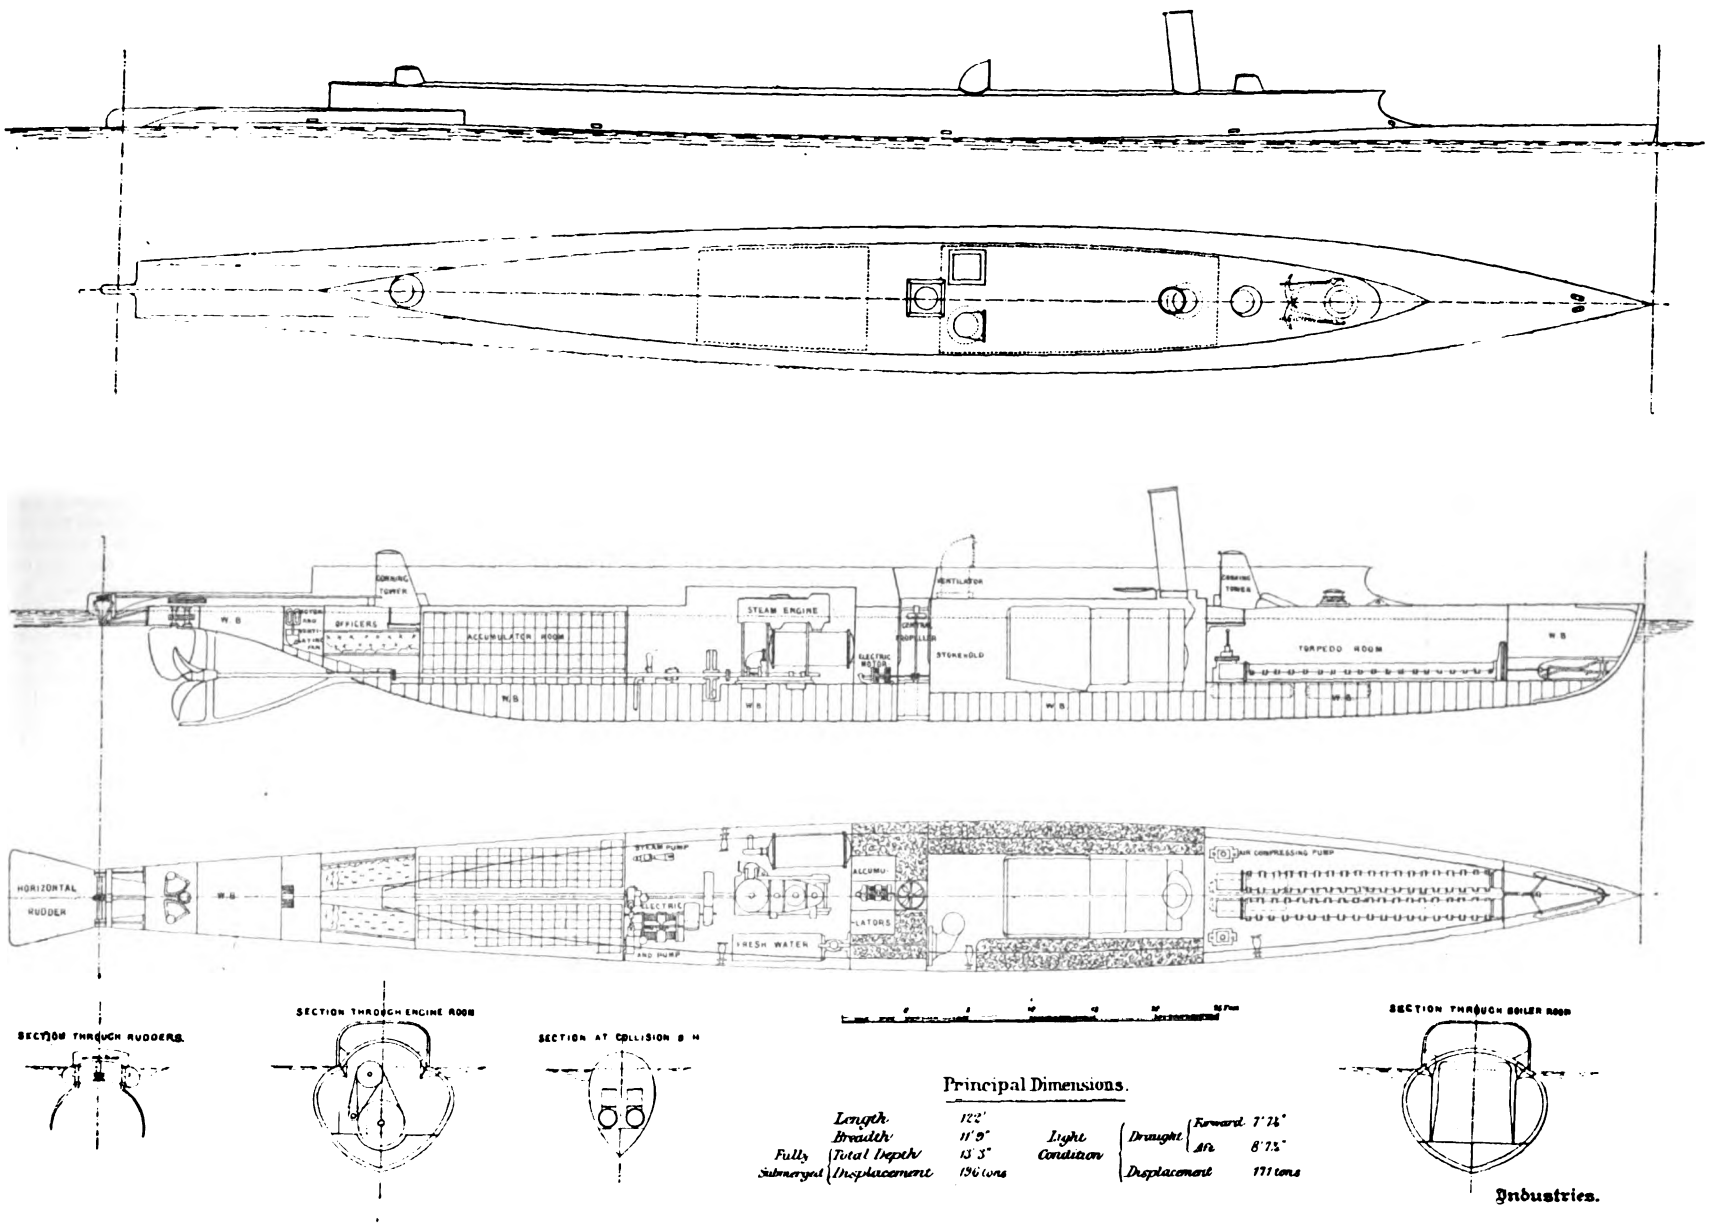
I.H.P. 250

At 11·8 knots speed, the i.h.p. for both screws was the same, viz., 565, and the e.h.p. is then 348.

At the close of the paper, Mr. White said that he was responsible for its having been contributed, and he considered it as of great value. There was, however, no discussion.

At the evening meeting of the same day the first paper read was by Lieut. W. Hovgaard, Royal Danish Navy, on some

Proposed Designs for Surface Boats and Diving Boats.



As the title implies, this paper was not a description of boats actually built, but of designs which the author, after six years of study of the subject, suggests as the most appropriate for two classes of boats—one a surface boat, with very little of her hull exposed above the water line, and the other a boat which may swim on the surface or dive below it, as circumstances warrant. The author, in his introductory remarks, hoped there would be a full discussion, by which the general solution of the problem would be advanced; but in this he was disappointed, the discussion being meagre to an extent which was very surprising, when we consider the great importance of the subject, and the ingenuity displayed by the author in his designs. In the surface torpedo boat, which we illustrate above, all the vital parts are placed below the water line, and just sufficient free board is retained to suit local requirements and to keep the connection with the atmosphere. In adopting these principles the author has limited the sphere of action for this boat to harbours and rivers where the water is smooth, and the boat can therefore only serve for the defence of landlocked waters. The following is a list of the qualities which he has endeavoured to obtain in this boat: A cost of not more than a second class torpedo boat; a speed of at least 13 knots; that she should carry two torpedo tubes in the bow; lowness of draught, to avoid mine fields, &c.; and that the top of the hull proper should be well under water, and on and above the water line should be protected by armour. All constant openings leading through the water line should be armoured up to 1ft. above that line, and surrounded by coffer dams. She should carry sufficient water ballast to alter her displacement within tolerably wide limits. At the deepest draught the centre of gravity of the water plane should be well forward, in order to prevent diving. There should be 6ft. head room inside the boat. The motive power should be steam, as connection with the atmosphere is maintained. The author has worked out the following dimensions for such a boat: Length over all, 78ft.; breadth, extreme, 7ft.; depth, 7ft.; maximum displacement, 63 tons; corresponding draught, 8ft.; corresponding speed, 13 knots; smallest displacement, 57 tons; corresponding draught, forward, 6ft. 1in.; corresponding draught, aft, 6ft. 7in.; corresponding speed, 13½ knots; cost, £8,000. The engine is a double compound vertical engine of the ordinary torpedo boat type. It is to develop 250 i.h.p. when running at 320 revolutions and with 130lb. pressure in the boiler. The coal bunker is placed athwartships, and holds 2½ tons of coal, sufficient for steaming a distance of 100 knots at full speed. The torpedo tubes are placed under the water, and are provided with horizontal lids. The top of the hull proper is 1ft. below the water, and is protected by 1in. steel plates above the boiler, engine, and steering gear. The conning tower is of 1in. steel plate, protected by 3in. armour 1ft. above and below the water line. The end and keel compartments are reserved for 6 tons of water ballast. The forward compartment is built up above the water to diminish pitching. Between the top of the hull proper and the deepest water line there is fitted a light superstructure, into which water is admitted when on the deepest water line. When the water is run out it gives a reserve buoyancy of about 8½ tons and 1ft. additional free board. The hull is constructed of ¼in. plating on frames 3in. by 2½in. by ¼in. placed 18in. apart. The weights are distributed as follow:—

	Tons.
Hull	26·0
Keel strengthening and bilge keels	7·5
Armour	5·5
Engine and boiler	9·5
Torpedoes and torpedo gear	4·0
Stores	1·0
Crew and gear	1·0
Various fittings	·5
Coal	2·0
Water ballast	6·0
Maximum displacement	63·0

For the light condition there will be about 2ft. of free board,

Digitized by Google

INSTITUTION OF NAVAL ARCHITECTS.

and the top of the funnel and ventilator will be more than 9ft. above the water. The transverse metacentric height will be 7½in., and the longitudinal metacentric height will be 7ft. The boat will usually move about in this condition; but when making an attack she should go down to the deep water line, or as deep as circumstances permit. The top of the conning tower, and of the funnel and ventilator, are 3ft. 3in. above the water at the deep draught. The transverse metacentric height is 9½in., and the longitudinal metacentric height 6ft.

The diving boat, shown in the above illustration, was designed so as to satisfy as far as possible the requirements of the United States Navy Department, as laid down in the circular which was issued last year, inviting proposals for the construction of a steel submarine torpedo boat. The circular stipulated for three conditions of the vessel: (1) Fully submerged to a maximum depth of 150ft., displacement not to exceed 200 tons, and power endurance to be at least two hours at eight knots, all connection with the atmosphere being broken off. (2) The covered condition, when the vessel was to be protected by 3ft. of water, but at the same time to have means of observing the object of attack through air. (3) The light or ordinary surface condition, when the vessel was to have some free board, and a power endurance of at least thirty hours at fifteen knots. The author found it impossible to comply fully with all the conditions, and in view of the great external pressure which would come on the boat when submerged to 150ft., and the corresponding increase in weight of hull, he has limited the submersion to 100ft., whilst the covered condition has been attained by increasing the depth of the superstructure to 3ft.

An interesting feature of the design is that both electricity and steam are used for motive power. The author prefers electricity stored up in accumulators to the hot water arrangement of the Nordenfelt boats, as giving greater speed and greater power of endurance, coupled with the advantage that the energy need not be used at once, but may be kept in store, and will always be ready for use when required. If a diving boat fitted with hot water arrangement has to be kept under water for some hours, the heat is dissipated, and she becomes helpless, whilst the electric energy stored in the cells can be indefinitely retained. For the surface condition, however, steam power is used as being more enduring and cheaper. The steam power is also used to charge the storage cells. The following are the principal dimensions of the vessel:—

	Ft.	In.
Length over all	122	0
Extreme breadth	11	9
Depth of hull proper	9	0
Height of superstructure	3	0
Top of conning towers above superstructure	1	3
Total depth	13	3
Draught in covered condition	12	0
Draught in light condition { Forward	7	7½
Draught in light condition { Aft	8	7½

Displacement, fully immersed.....196 tons.
" covered.....a few cwts. less.
" light conditions .....171 tons.

The distribution of weights is as follows:—

	Tons.
Hull	96·5
Keel strengthenings	6·5
Steam machinery with water	24·5
Electric machinery	3·5
Coal	8·5
Accumulators	19·0
Torpedoes and gear	6·0
Various fittings	2·5
Stores	1·0
Crew and gear	1·5
Water ballast	25·0
Water constantly carried (in screw well, &c.)	2·0
Displacement when fully submerged	196·0

In the fully submerged condition a small amount of reserve buoyancy is retained, the immersion being effected by means of a small propeller, placed amidships, and capable of giving a vertical thrust. When this propeller is stopped, the boat will place herself in the covered condition, *i.e.*, with the top of the superstructure just in the water line, and the conning towers out of water, the superstructure being filled with water. When the water ballast, normally 25 tons, is pumped out, she will gain 4ft. free board, and will trim 12in. lighter forward. The water will have run out of the superstructure through doors placed as low as possible, and if these doors be now closed water tight, the vessel will at once obtain considerable reserve buoyancy. In order to obtain the necessary strength of hull to resist collapsing when the boat is submerged 100ft., the frames are deep and have been put close together. The total capacity of the water ballast tanks is 31 tons, and the capacity of the bunkers is 13¼ tons. The water is admitted to the tanks through several sluice valves, large enough to allow the tanks to be filled and the boat to sink within half a minute, and the water may be pumped out either by electric, steam, or hand power. The steam engine is vertical compound surface condensing developing 600 i.h.p. at 315 revolutions. The boiler is of the ordinary locomotive type, designed for a working pressure of 125lb. The dynamo is connected with the propeller shaft by friction gear. The speed at full power in the light condition is 14 knots, and endurance 19 hours. The dynamo is capable of developing 35 h.p. when supplied from the storage batteries with a current of 245 ampères at a pressure of 148 volts. The speed of the dynamo is 600 revolutions, but this is geared down by means of a counter shaft and belting to 120 revolutions of the propeller shaft, which must be disconnected from the engine when electricity is used for propulsion. In that case the speed of the vessel is 5½ knots and the endurance six hours. The same dynamo when worked from the main engine is also employed for charging 540 storage cells, each weighing 79lb., and giving a discharge current of 35 ampères for six hours. The vessel has even in the

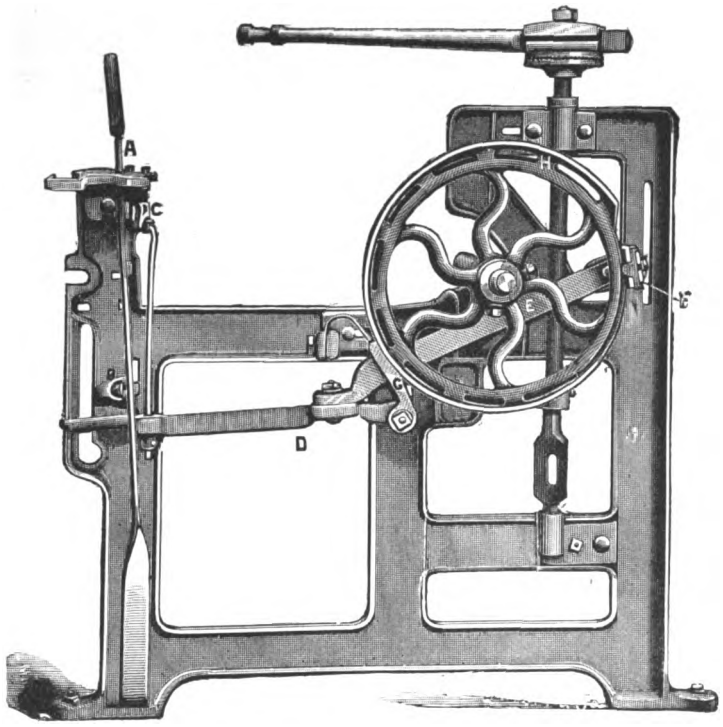

Fig. 66.

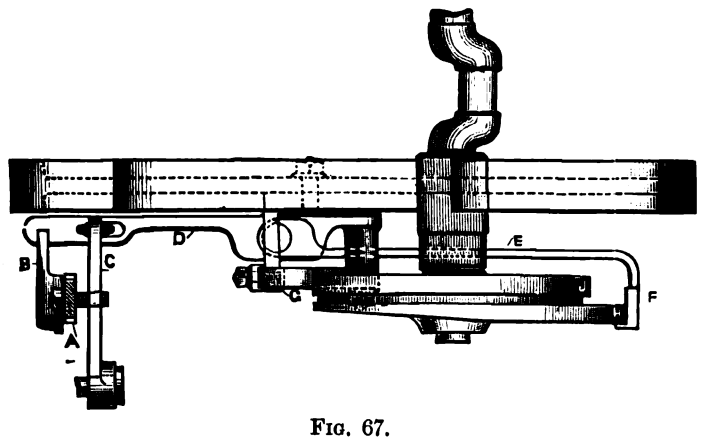

Fig. 67.

submerged condition a slight excess of buoyancy, and downward movement is effected by a small propeller on a vertical shaft working in a tube. This propeller is worked by a 5 h.p. electric motor, and by reversing the current through the armature can be driven either way, so as to make the boat rise or sink. When travelling submerged the reversion of the current is effected automatically through the action of the water pressure on a reversing switch, the instrument being so adjusted as to keep the boat at a certain desired depth of immersion. There is also fitted a horizontal rudder which may be used for rapidly changing the depth of submersion when the boat is travelling. When submerged the air is kept fresh by taking away the carbonic acid produced by exhalation and adding oxygen. For this purpose the air in the boat is circulated through a solution of caustic soda, 300lb. of which would suffice for twelve hours when the boat carries her usual crew. The oxygen is added from a reservoir under pressure. The vessel carries two torpedo tubes, and the torpedo gear and appurtenances are similar to those of a first class torpedo boat.

The discussion was opened by Mr. Nordenfelt, who hoped the author would be successful, but doubted the desirability of using electricity as a motor power. Steam was unquestionably more convenient at the surface, and it would be quite possible to keep up a sufficient pressure of steam for the time the boat remained below. Before such a boat is built it must be clearly settled whether it is intended for harbour or sea work. He admitted that if the vessel were to remain under water for twenty-four hours steam would be useless, but he imagined it would never lie idle for more than a few hours. The weight of the accumulators would be a disadvantage, and as in such a boat simplicity is of the utmost importance, he would prefer to dispense with electricity, even at the cost of limiting the requirements to what steam can do. He believed in the future of these boats, which are now being studied by all the Powers except England and Germany. England would find them convenient for the defence of outlying ports.

Mr. Martell was glad the paper had been read before the Institution, but could not conceive the intention for giving a boat 122ft. long a shell plating $\frac{5}{8}$in. thick, and deep frames spaced 12in. It seemed utterly unreasonable, as such scantling would suffice for a cargo ship of at least 2000 tons. In reply to this speaker,

Mr. McFarlane Gray pointed out that the boat was to be used for submarine work at a pressure of 76lb. per square inch, and therefore strength was necessary.

Mr. Hovgaard, in reply to Mr. Nordenfelt, said that electricity did not compare unfavourably with steam, as the weight of water, if required, would have been 25 tons, while that of the accumulators is only 22·5 tons. The endurance at $5\frac{1}{2}$ knots is six hours. He predicted that Mr. Nordenfelt would be using electricity as a motive power within a few years. In answer to Mr. Martell, he stated that if the scantlings were the same as that of an ordinary torpedo boat it would not withstand the pressure of 10ft. of water, whereas this boat has to resist that of 100ft.

THE MANCHESTER ROYAL JUBILEE EXHIBITION.

Textile Machinery *(continued from page 286)*.—Where yarn used as weft is coloured after being dyed in the hank it is wound on to "pirns," or long thin tubes with inverted conical heads. The winding is first effected on the conical part, which is placed in a cast iron cup shaped to receive it. The pirn is driven by a spindle, formed with two flat sides at the point where it passes through a corresponding slot in a warve conveniently held and driven. The warve has a heavy button at its upper end, which is formed with projections at its under side fitting into notches in the head of the pirn. As the pirn is covered with yarn it lifts slowly, the traverse of the guide being arranged to correspond with the depth of the cup. Only one machine was exhibited of this class, and that was a special one for winding silk, by Messrs. Nightingall Brothers, Paterson, United States. In this case, instead of the pirn or "quill" being placed in a cup, it is held at the end of a round plunger, which is gradually raised, and the yarn wound on by means of the rotation of a flyer eye, through which it passes. Arrangements were made in this machine for winding several ends on to one pirn, and a stop motion of the drop wire type was provided for each spindle, so that in the event of the failure of any of the ends its corresponding pirn was stopped.

Having now referred to all the machines used for the preparation of yarn for weaving, it becomes necessary to deal with the various looms exhibited. It is scarcely requisite to go into any description of the process of weaving, as this is well known; but we may briefly describe the various looms, beginning with the simplest form as shown in the plain calico loom. A typical specimen of this class of loom was exhibited by Mr. George Keighley, Burnley, which was kept working at a very high rate of speed. The reed space was 36in., the slay being the maker's special iron one, which avoids any unevenness in the "race," and prevents the jumping of the shuttle, which often occurs with the ordinary construction. The breast beam over which the cloth passes is dispensed with, the taking-up roller occupying its position. The space between it and the reed being much reduced, a steady pull is put upon the cloth, and "sagging" is entirely avoided. The same firm showed a twill loom, in which the treadles operating the healds are fixed underneath and at the back of the loom, so that no space is occupied unnecessarily. The treadles are arranged to be driven by a pinion on the counter shaft. The spindle carrying the treadles has a pinion at each end, and by putting one of these in gear with that on the counter shaft the necessary movement is obtained. The change is made by disengaging one pair and engaging the other, a different effect being in that way produced. The loom shown by Messrs. Wm. Dickinson & Sons, Blackburn, has an ingenious motion for weaving handkerchiefs. The tappets are, contrary to the usual practice, loose upon the shaft, and are driven by clutches which can be disengaged when desired. They are put out of gear by a set of lattice bars, the pegs in which are arranged for this purpose. In this way a border can be woven first and a plain portion subsequently, for any desired length, the whole being controlled by the pegging of the pattern chain. The lattice barrel is thrown out of action during the weaving of the plain part, and is again thrown into motion by means of a cam, which makes a complete revolution while the requisite length is being woven, a greater or less speed being given to it by change wheels. The cam surface has on it a notch occupying about a quarter of the circumference in length, in which are two movable brackets which divide it into two spaces. When the required plain part has been woven, a lever which rests on the cam drops into the first space and throws the catch of the lattice barrel into gear, thus regulating the treading and forming the pattern. The continued revolution of the cam causes one of the brackets mentioned to lift the measuring lever and stop the motion of the lattice for the necessary time to allow of the weaving of the plain space between the borders of two handkerchiefs. The lever then falls into the second space, and the border of the second handkerchief is woven, when the lever is again raised, and does not come again into operation until the whole of the plain part is finished. This motion is very ingenious and effective, and allows of handkerchiefs being produced without using a drop box motion.

One of the most ingenious of the various contrivances applied to looms was that known as Haythornwaite's automatic brake, which was exhibited on the stand of Messrs. John Dugdale & Sons, Blackburn, and applied to a loom made forty-five years ago. The condition of the loom amply verified its age, and the work which it had performed. This device is illustrated in Figs. 66 and 67 in side elevation and plan. The ordinary fly wheel has a projection H cast on one side of it, gradually rising until it is $\frac{3}{4}$in. higher than the true circumference of the fly wheel. When the weft breaks, the block G is put into contact with the raised surface H. On the other end of the lever E is the block F, the relative positions of F and G being shown in Fig. 66. Now it may be seen that, as long as G is kept out of contact with H, the revolution of the fly wheel is unchecked; but when G is thrown over, the distance between F and G is such that the greater diameter of the wheel across the raised part of H prevents it passing between the two surfaces. The advantage of this arrangement is two-fold. It first arrests the motion of the loom gradually, and it does so always at one point, which can easily be arranged so as

Digitized by Google

to be that which is most convenient for the weaver. Being absolutely certain, any wear in the loom does not affect it, and perhaps, on the whole, it is about the best device extant for the purpose.

Among the minor improvements to be noted was one on a loom shown by Messrs. Willan & Mills, Blackburn, and was an improved method of fixing the fly spindle. Instead of fixing the spindle by pushing it into a nipple at one end, and keeping it so fixed by a spring at its outer end, two grippers are used, these being attached to the slay beam. The spindle can be easily slipped into position, and by fastening up the nut is securely held. This, though only a minor improvement, is of considerable value. In the loom shown by Messrs. Butterworth and Dickinson, Burnley, there was an arrangement of the loose reed which gets over many difficulties attending its use ordinarily. The reed is pivoted at the bottom by means of a horizontal rod attached to the slay cap. Two projecting pieces are attached to the rod, which keep the locking pieces in position by means of connecting rods. When the reed is beating up, the locking piece passes on to a strong bar placed vertically, which has a "duck bill" projection formed on it. If an obstruction occurs and the shuttle is caught in the shed, the reed, being pressed at the top by it, readily yields, and the locking piece passes under the duck bill. By this arrangement all the advantages of a fast reed are obtained, and, in addition, the easy manner in which the reed can be pushed back insures that no breakage of the warps will occur, even when fine cloths are being woven.

In the class of looms designed to weave more elaborate fabrics there were several fine exhibits, and in dealing with them there are two main features to be considered, viz., the motions used for giving different colours to the weft, that is, the drop box motions, and those intended

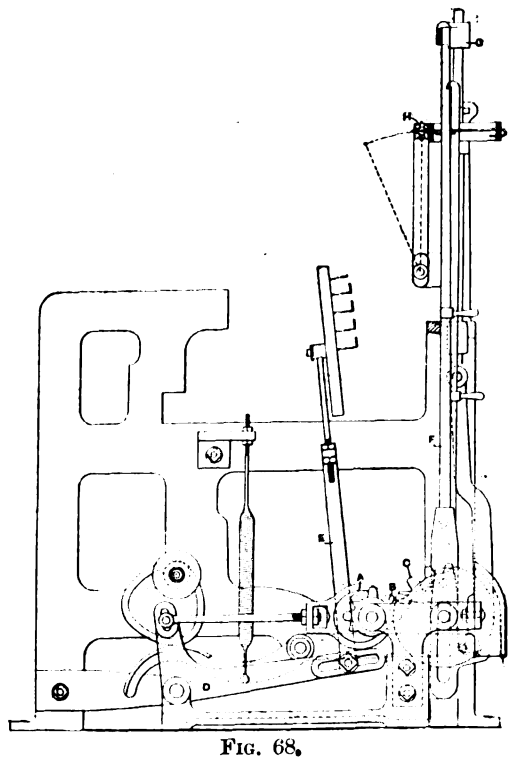

Fig. 68.

to manipulate the warps, which include all the dobbies and Jacquard mechanism. Taking these in order, in Fig. 68 is illustrated a drop box motion, shown by Messrs. Hacking & Co., Bury, which is of great merit. The essential feature of this mechanism is the use of two eccentrics A, one enclosed in the other, by altering the position of which the necessary changes of the boxes are made. The mechanism employed will be presently described. The position of the eccentrics is shown in Fig. 69, as they are when each box, of which there are four, is in its right place, the dotted vertical lines showing the movement of the rod attached to the eccentric straps. The eccentrics do not revolve, but simply oscillate about their forward and back centres. It will be seen that both may be thrown over together, and so make the change from the first to the fourth box, or only one may be moved, with the consequent single change. On one of the eccentrics is a sector B gearing with a second sector C formed on a disc suitably carried on a stud. On the inner surface of C are pins, with which projections formed on the upright rods F engage. The top of F is hooked, and a catch G on the upper end of a vertical rod, having a constantly reciprocating motion, engages with the hook, unless it is pushed out of the way by needles operated from the barrel H. H, as shown by the dotted line, has a swinging movement, and has on it a pattern chain. The motion, as described, is that intended for one eccentric; but a similar arrangement is applied to the other. On the discs attached to the eccentrics are a second set of pins, by which the return oscillation of the eccentric is obtained. The working of this mechanism will be easily understood. When one of the levers F, by reason of the hole in the card, is allowed to remain in its inner position, the vertical movement of G lifts it, and so rotates its

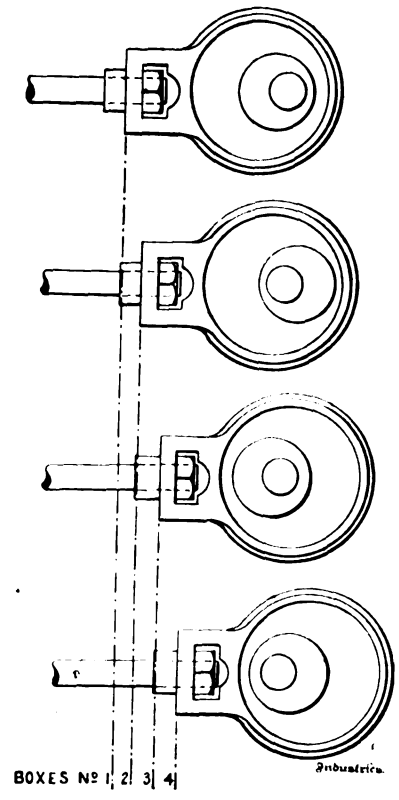

Fig. 69.

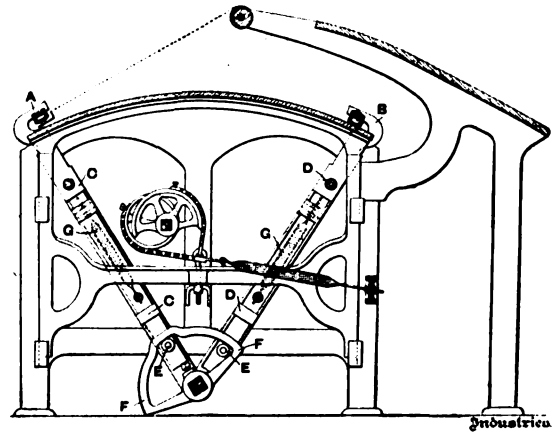
special eccentric. If both eccentrics are to be moved, two hooks are raised, and it entirely depends on those raised which of the boxes is brought into position. When the eccentric is so rocked, the lever D is oscillated, and the rod or bar E, by which the boxes are carried, is raised or lowered. By means of the spiral spring shown, the raising of the boxes is aided, their weight being sufficient to bring them down easily. Handles are attached to the rods F, and any desired change can be made by hand.

The folding or plating machine which was exhibited by Messrs. Hacking & Co., Bury, is illustrated in Fig. 70, and has several points of interest. The cloth is folded by blades fixed at the end of a long arm, not shown in the illustration, and pivoted at its lower end, being driven by means of a disc and connecting rod. The novelty in Messrs. Hacking's machine consists in the construction of the grippers A B, which are fixed at the end of diagonal arms C D. On the lower ends of these arms are bowls E, engaging with the inner surface of the cam F, which is



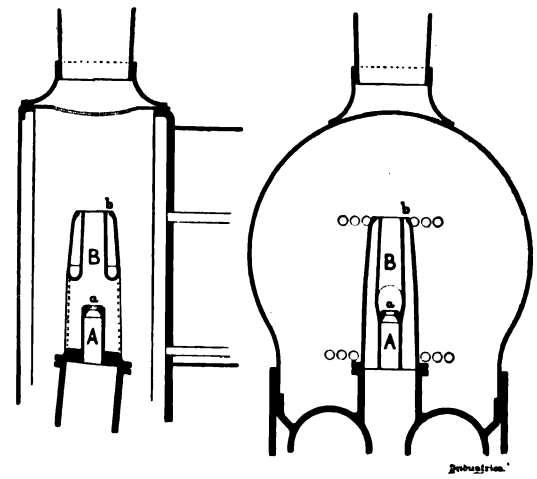


Fig. 70.

attached to and oscillated by the folder arm. The gripper rails A B are arranged to be pulled upward by the spiral spring G, to allow of which there is a recess in the cam F. This upward movement occurs just before the knife passes under the gripper, in this case A, and as soon as the cloth is laid and the blade recedes the cam pulls down the arm again, and so grips the cloth firmly. This motion takes place alternately at each end of the fold, and as the rails are lined with corrugated rubber, no damage occurs even to the finest class of goods.

(To be continued.)

ADAMS' "VORTEX" BLAST PIPE.

The improved "Vortex" blast pipe illustrated herewith, is the invention of Mr. W. Adams, locomotive superintendent of the London and South-Western Railway. The ordinary locomotive blast pipe consists of a central pipe, connected by a breeches pipe to the exhausts from the two cylinders, and the exhaust steam is discharged centrally up the chimney, producing a vacuum in the smoke box, and thereby creating the draught. Mr. Adams, like many other locomotive superintendents, found that the lower tubes in the locomotive boiler were practically ineffective, as they frequently became choked; and in seeking a cure for this defect he tried various forms of blast pipe, and ultimately invented and patented the vortex, which is similar to the arrangement shown in the engraving, but without the central jet. In the vortex the two exhaust pipes are united by an annular chamber or ring, with a central opening through which a portion of the products of combustion is drawn, the principle being similar to that of an injector. The vortex blast pipe was found to improve the draught, to reduce the consumption of coal, and to considerably diminish the choking in the lower tubes; but with a view to completely eliminate the last mentioned evil, Mr. Adams continued his experiments with varying sizes of central openings, and with various heights for the top of the blast pipe. The latest improvement is that shown in our illustration, and consists in the addition of a central nozzle at

a lower level than the main orifice. By thus sub-dividing the ejector into two parts the draught through the lower tubes is considerably improved, and choking becomes almost impossible. The effect of this arrangement is also to greatly improve the steaming power of the boiler, and the remainder of the locomotives on the London and South Western Railway not yet fitted with the ordinary vortex blast pipe will be fitted with this improved type. It has been found that the best height for the top orifice is level with the top of the boiler tubes. In our sketch A is the lower blast pipe, terminating with a nozzle *a*; whilst B is the usual vortex blast pipe, with an annular chamber and annular jet. The combination of the central jet and the annular jet produces a powerful draught, and equalises to a certain extent the pressure throughout the smoke box, so that all the tubes become equally effective.

From a statement prepared by Mr. Adams, we find that out of a total of 534 engines, which were in service at the end of last year, 253 were fitted with vortex blast pipes. The total engine miles made during the half year ending the 31st December, 1887, was 8,528,045, and the cost for fuel was £67,166. In the half year ending with June 30th, 1885, none of the 505 engines then in service were fitted with vortex blast pipes, and the cost of fuel was £72,226, coal being taken in both cases at 13·94s. per ton. The saving attributable to the adoption of the vortex blast pipe is calculated at £9,552 for the last half year. The consumption of fuel per engine mile was 26·3lb., as against 29·9lb. when all the engines were fitted with the ordinary blast pipe.

Trade in Austria.—Notwithstanding the general depression of trade reported to prevail in Austria, we come across some industries which are in a very flourishing condition. The Vienna Brick Making Company have issued their balance sheet, which shows that during the past financial year the net profits amounted to 600,000 florins, on a total capital of 4,000,000 florins. The Perlmooser Cement Factory has an equally satisfactory balance sheet, showing on a total share capital of 22,000,000 florins a net profit during the past year of 191,000 florins, being a dividend of nearly 9 per cent.

FOREIGN INDUSTRIES.

(From our own Correspondents.)

PARIS, 10TH APRIL, 1888.

THE IRON MARKET.—The holidays being over, and the weather having become mild again, building operations have been resumed, and are now being pressed forward vigorously. The effect of this renewed activity is visible in the iron market, which has become animated and firm. Joists are in brisk demand. Manufacturers have utterly ignored the proceedings of the merchants, and advanced the prices to £5. 16s. for bars and £5. 8s. for joists. This resolute action on their part has steadied the market and infused life into business generally. Old rails are still officially quoted at £3. 4s. a ton, but dealings have taken place at higher figures. In the Haute-Marne business has fallen off in bars, but wire remains in good demand. Complaints of lack of orders indicate less life in the Ardennes; but from other centres of the iron industry more cheering reports have been received. Founders are everywhere busy, and the prices of light castings are following the upward movement of the heavy goods. The Compagnie de Commentry-Fourchambault and the Société Metallurgique du Périgord have secured the contracts for several thousand tons of cast iron pipes for the town of Pointe-à-Pitre, South America.

THE METAL MARKET.—The situation grows more and more unfavourable to the maintenance of the abnormally high price of copper. Consumers buy but little, and stocks steadily increase. Tin shows a more marked tendency to weakness, and dealings for future delivery take place at prices considerably below official quotations. But these concessions are not sufficient to tempt consumers, who buy only for present use, in the belief that a collapse of the market is near at hand. Lead is unaltered. Spelter has slightly receded in price.

WORKMEN'S RELIEF FUNDS.—The Chamber of Deputies has under debate a Bill which, as an earnest attempt to improve the material condition of the working classes, and to lessen the tension existing in the relations between capital and labour, is of no little importance to industry, and which will excite interest outside the limits of French territory. The legislation asked for is for the present solely on behalf of the miners, the scheme having emanated from them, and being regarded as an experiment. If, however, it is found to be satisfactory, it is to be extended to all industries. The measure in question provides for the payment, in equal proportions by both employers and employed, of a sum of money monthly into funds established for the relief of the working men in sickness and in old age. These payments are to amount to 5 per cent. of the wages. From the money so contributed, will be maintained (1) a sick fund; (2) a relief fund for cases of accident; and (3) an account with the *Caisse Nationale des Retraites pour la Vieillesse*, from which an annuity will be paid after the age of fifty years has been reached. This annuity is to be in part reversible to the wife in case of decease, and any balance remaining after the death of the latter is to be returned to the next of kin. It will be observed that for the employer the measure involves what is practically an increase of 5 per cent. on the rate of wages paid.

UNDERGROUND ELECTRIC TRAMWAY,—The Third Commission of the Municipal Council of Paris has under consideration a project of an underground electric tramway to connect several of the chief points of this city. The project, due to M. Berlier, a civil engineer of repute, has been examined and reported on favourably by the engineers in the service of the municipal authorities. Considerable interest is felt in this scheme apart from its public utility, on account of the many novel points involved. There are to be three lines running from the Place de la Concorde, one to the Bois de Boulogne, another to the Place de la Bastille by way of the great Boulevards, and the third to the Porte de Vincennes by way of the Rue de Rivoli. All these lines are to run underground for the whole distance. The tunnel, instead of being constructed of masonry in the usual way, will be formed of a cast iron tube of circular section and 6m. in diam. It is proposed to construct these lines without opening the streets at any point. The tunnels, the stations, and the cars are to be lighted by electricity. One great advantage will be the good insulation which it is possible to maintain in an underground line of this character. The estimated cost for the whole length of a little more than 16 kilometres is £2,160,000, an average of £129,400 per kilometre. The Bois de Boulogne line may, it is said, be finished in time for the Great Exhibition of next year. It is proposed to run, if the traffic requires it, a tram car every minute, an interval of time amply sufficient to insure safety with the arrangements to be adopted.

BERLIN, 9TH APRIL, 1888.

THE COAL MARKET.—There is a good demand for coal, especially for household qualities, owing to the exceptionally bad weather which has been experienced this season. There has been an unusual consumption of nuts, and as contracts had been made for large quantities for metallurgical purposes, there has been some difficulty in meeting the demand. Considerable quantities of anthracite have been exported, and this kind finds a ready sale in Upper Silesia for the manufacture of coke. Some imports of Polish coal into the eastern provinces have taken place, but as the best of these are only equal to the second quality of Silesian coal, and as the prices are higher, it is not likely that they will continue to be imported. At a meeting of the large Westphalian collieries connected with the Berlin Discount Company, which has just been held in Berlin, it was decided to establish a coal sales bureau in Westphalia. Other unions of a similar character are now spoken of, and if they be found to work well, it is intended to form the whole into a large syndicate.

THE IRON MARKET.—A fairly active business in crude iron is being done in Upper Silesia. Foundries are well employed, and there is plenty of work in large castings. Rolling mills are also well supplied with orders, and in some cases have to work overtime. The demand for bar iron continues to improve, and there is also great activity in large sections. The outlook for the latter is very favourable, but as far as Russia is concerned business is not satisfactory. Plates are in fairly good request. The iron trade generally is in a satisfactory condition, and an improvement in prices is expected. The syndicate of wire nail manufacturers has been greatly strengthened by the Saxon group having now joined them, and it is expected that those works which have as yet held out will ultimately join.

SUGAR.—The interruptions to traffic caused by the recent heavy snowstorms have had the effect of keeping the sugar market very quiet. The demand for refined sugar is weak. Refineries are only disposed to make purchases at very low rates, and therefore but little business is being transacted, since producers decline to accept orders at prices which would leave a small margin of profit. Exporters are not much interested this year in crystallised sugar, as the prices obtainable abroad for this article are not sufficiently remunerative.

ELECTRIC LIGHTING.—A committee, appointed by the Town Council of Breslau to inquire into the best means of installing the electric light in the town, has reported in favour of a large central station to supply 5000 lamps, distributed throughout an area the boundary of which is at no point farther than 1200 metres from the generating station. It is not intended to ask public tenders for this installation, but to entrust it to Messrs. Siemens and Halske, of Berlin, who will submit an estimate based upon a general plan of the district. The management of the central station will be in the hands of the municipality. These recommendations of the committee have not yet been finally adopted.

PETROLEUM.—Many complaints have lately been made regarding the inferior quality of petroleum which is constantly being placed on the market. With a view to remedy this state of affairs, the Society of Colonial Merchants in Hamburg have remonstrated with the petroleum dealers on the Hamburg Exchange. This protest has had the desired effect, the Hamburg dealers having promised that in future they will not place inferior petroleum on the market.

LEATHER.—The recent severe weather seems to have had a depressing influence on most trades. The leather branch is no exception to the rule, and the condition of the market at the present time is not very satisfactory. This state of affairs is rendered worse by the fact that the large orders for leather military articles, which have hitherto kept manufacturers fairly well employed, have now come to an end. The supplies of most leather articles at present are not very large, but they are still sufficient to exceed the demand, and reductions in price are being made in consequence.

VIENNA, 9TH APRIL, 1888.

THE IRON MARKET.—The exceptionally fine weather of last week has given a considerable impetus to nearly all the branches of the iron trade in Austria, and even in Hungary the situation has improved. Primarily the change affected merchant bars, girders, and building iron of all kinds, but the greater activity in these articles has also had a salutary influence on the crude iron market. Stocks were low before the holidays, and dealers expecting the usual development of business after Easter, have come into the market with fairly good orders. Iron founders have as yet not participated in the improvement, but engineering works are busy with orders for sugar factories and distilleries, and the prospects of the coming summer are better than they were at the same time last year. The small iron and hardware business is also improving; after the enforced idleness of many small works, who suffered from scarcity of water power during the severe winter, the change is very welcome. The Witkowitz works have booked a large order for bolts, nuts, plates, and other accessories for the Galician Railway. The wire syndicate has now been definitely established on lines similar to those adopted by the rolled iron syndicate. No attempt will be made to fix prices, but the works have agreed to a certain proportion of output for each, and in this way the adjustment of prices will be brought about in a more natural manner. Two of the largest Bohemian iron and mining companies have just issued their balance sheets. The Prague Iron Company shows, for the last half year's working, a net profit of 200,000fl. (£15,800), and the Moutan Company shows, for a whole year's working, a net profit of 90,000fl. (£7,100). The original share capital of this company was 2,000,000fl. (£158,000); but half of this has been written off some years ago, so that the net dividend amounts to 5·2 per cent.

RAILWAYS.—The total length of Austro-Hungarian railways open for traffic in February amounted to about 15,000 miles (exclusive of sidings), and during that month there were carried 3,534,099 passengers and 5,300,774 tons of goods. The receipts amounted to 17,398,276fl. (about £1,370,000), or £91 per mile, which is 3·2 per cent. less than the corresponding figure for the same month last year. The volume of traffic has thus increased at a faster rate than the receipts. This is partly due to the keen competition and consequent cutting of rates between rival lines. To mention only one instance: Some time ago the Hungarian State Railway allowed a discount of 30 per cent. on their mileage ticket books on the route Vienna-Bruck-Budapest, if the value exceeded 50fl. This concession did not, however, seem to have had the desired effect of diverting a considerable amount of traffic from the Austrian State Railway on the route Vienna-Marchegg-Budapest, and therefore the Hungarian line reduced the price of ordinary tickets below that charged by the Austrian line, and, moreover, increased the discount on mileage ticket books to nearly 50 per cent.

STEAM BOILER LEGISLATION.—In the beginning of 1883 a law was passed putting boilers erected within the town of Vienna under police regulations; but this law was found to impose too many restrictions upon the owners of small boilers, and thus to damage domestic industries. The owners of small boilers have repeatedly asked for an amendment of the regulations, and now the Vienna Society of Engineers have taken the matter in hand, and at their last meeting they resolved to petition the Ministry to pass a new law which would facilitate the employment of small steam boilers. The following are the more important provisions the adoption of which will be suggested to the Ministry: Boilers constructed entirely of tubes not exceeding 5in. internal diameter may be installed either in dwelling rooms or below them; and in the latter case it is not necessary that the ceiling of the boiler room be arched, a provision which is insisted upon when larger boilers are used. So-called "small boilers," which are not wholly constructed of tubes, but the shell of which does not exceed 4ft. in diameter, the quantity of water up to the working level in the glass does not exceed 1 ton, and the steam pressure does not exceed 120lb. per square inch, may be erected in dwelling houses, provided the room above is not used as a sleeping room. The ceiling of the boiler room may be either arched or may be the ordinary ceiling of dwelling rooms with wooden beams. The boiler must not be less than 6ft. 6in. distant from the walls of neighbouring apartments. Tubular boilers will be classified as "small boilers" if the tubes are not more than 5in. in internal diameter, and if the steam pressure does not exceed 150lb. per square inch. These boilers may be provided with a water leg and steam collector; but the total quantity of water contained in the boiler must not exceed 1 ton, and the largest diameter of any part must not exceed 4ft. The steam collector must not be exposed to the fire gases, nor be bricked or cased in in any way, and must be at all times accessible. Boilers will be classified as "dwarf boilers" if the total amount of water does not exceed half a ton and the greatest diameter does not exceed 3ft., and the highest steam pressure does not exceed 90lb. These boilers will come under the ordinary regulation of domestic stoves, hearths, and fire places. If boilers of the above dimensions contain tubes not more than 4in. in diameter, they will be classified as "dwarf boilers," and a steam pressure up to 120lb. will be permitted. These boilers must not be bricked in, and steam reservoirs must be at all times accessible. Boilers in which the pressure does not exceed 7½lb., and the water in which is in communication with a vertical pipe open at the top, are classified as low pressure boilers, and are exempt from all police regulations. The last clause, if adopted, will be of importance to the makers of low pressure domestic motors.

BRUSSELS, 10TH APRIL, 1888.

THE COAL MARKET.—The Belgian State Railway contracts made last week for 335,000 tons of coal show a marked rise at Liège and Charleroi. As compared with the rates obtained at the contracts made last August, the price at Liège has risen 1s. per ton, and at Charleroi 10d. per ton. The present rates are 1s. 8d. more than those of the great contracts of September, 1886. This shows that the market is very firm, and complaints are now heard of the scarcity of industrial coal, of which the stocks are very low. During the week ending 25th March, the number of waggons on the State Railways carrying coal was 20,943, against 19,151 in the corresponding week of last year. The exports of Belgian coal to the North of France are rapidly increasing, and are driving English coal out of the Boulogne and Dunkirk markets. In addition to the Belgian-Westphalian coke syndicate, to which I referred in my last letter, another is being formed by the coke makers of the Centre, which turns out half of the total Belgian production. The makers in the Mons, Charleroi, and Liège districts have decided to wait till they see what success attends this movement, before they take similar action. The Administration des Mines Belges is experimenting in fiery mines with Settle's safety cartridge.

THE IRON MARKET.—Pig iron continues firm. The Charleroi and Athus works have increased their prices about 4s. per ton since the beginning of the year. Forge pig is quoted at 38s. 5d. at the Athus works, and strong iron at 44s. at Charleroi. These high rates have resulted in large quantities of puddled iron being imported from Cleveland, and are giving an impetus to the demand for the abolition of the duties on crude iron. A deputation of manufacturers of finished iron, who have no blast furnaces of their own, was received last

Digitized by Google

week by the Minister of Finance, to whom they pointed out the unfairness of maintaining a duty of 4s. 2d. per ton on forge pig while foundry pig and pig for steel making purposes are admitted free. The Minister referred the deputation to the Department of Public Works. There is, however, little chance of the Government taking steps in the matter, as the existence of duties on food stuffs renders it difficult to abolish duties on industrial material. The price of steel rails has fallen very low, as shown in the contracts for the Portuguese railways. Makers of manufactured iron are beginning to have some difficulty in obtaining fresh orders. French girders are being exported *vid* Antwerp in competition with Belgian girders.

The Brussels Exhibition.—The nearer the time approaches for the opening of the Exhibition the more certain it is that it will not be ready. Difficulties have arisen between the Government and the Exhibition Company which cannot fail to cause delay. The central hall will not be ready, the machinery section is yet without flooring, and the garden pavilions are also in a backward condition. The machinery therefore cannot yet be fixed. The contracts for the electric lighting of the Exhibition are also yet unsettled, and the number of lighting hours now spoken of is ridiculously low.

Small Arms.—The Liège Arms Factory is well supplied with orders, and commissions are expected from the Belgian Government for the manufacture of the new infantry rifle, the War Department having organised a competition in order to decide on the type. The calibre is fixed at eight millimetres, so that the competition only extends to the breech mechanism. Trials are being made with seven kinds of rifles, among which are those of M. Pieper and Captain G. Tua. For the latter rifle it is specially claimed that there is no tendency to disturb the aim by the recoil. It is a magazine rifle, and at the recent trials the charging of the magazine with cartridges only occupied twenty-three seconds. The speed when using the weapon as an ordinary rifle was fifteen rounds a minute, but by using the magazine the fifteen rounds only occupied twenty-five seconds.

DÜSSELDORF, 9th April, 1888.

The Iron Market.—The amount of business now being transacted in the iron market is considerably below the average of the last few months; yet it would be scarcely correct to describe the situation as being in a corresponding degree weaker. Consumers have all bought far forward into the year, so that the same amount of activity is not to be looked for. It was stated at the meeting of the Pig Iron Association, held at Cologne last week, that some of the blast furnace owners have sold the whole of their make of pig down to the end of the current year. Of course, in circumstances like these, and with syndicates in every branch of the trade, prices remain firm. Spiegel pig is in fair demand for home consumption, but only a small business is being done on export account. Forge pig is relatively but little sought after. There is a brisk demand for Bessemer pig, and basic steel pig is being largely dealt in. In this class of iron, English competition is now very keen, Middlesbrough pig being delivered here at from 2s. to 3s. below the prices of native iron. Luxembourg foundry pig is slightly higher in price. The market is, on the whole, quiet for finished iron and steel. Bars are in slightly better demand for home consumption, but sales on foreign account become fewer and less important. The break up of the frost has enabled builders to resume work, and joists are consequently in fairly brisk demand. Plate manufacturers in this locality have plenty to do, but in the Siegen district complaints are heard of a lack of orders. The trade in sheets, however, is dull even here, and some manufacturers have work in hand sufficient only for a very short time to come. The export trade in wire remains languid. The latest tenders for steel rails gave £6 as the lowest price. Engineers are for the most part very busy.

German Iron Abroad.—The Customs returns for the second month of the current year tell the same tale as those for the first. The tendency of the export trade to shrink is very marked, justifying the apprehensions for the future of this trade, founded upon the excessive prices established by the syndicates. The following are the quantities exported in January and February, compared with those for the corresponding period of last year: Pig iron, 26,619 (35,621) tons; scrap, 4049 (9616) tons; half wrought iron—blooms, ingots, and puddle bars—5161 (7096) tons; finished iron—bars, angles, and plates—35,799 (45,865) tons; wire, 33,990 (43,289) tons; rails, 13,181 (29,091) tons; other railway iron, 4947 (4744) tons; manufactured goods other than machines, 31,859 (26,179) tons; total, 155,605 (201,502) tons, a decrease of 22·77 per cent. The total for the month of February amounts to 77,183 tons, against 78,422 tons in January. Angles and plates show a considerable increase, but bars have declined from 34,848 tons last year to 18,833 in 1888. There is an increase in nearly every class of manufactured goods. The larger exports of wire nails, 6956 tons against 6098 tons, is doubtless due to buying in anticipation of the higher prices to obtain which the syndicate was formed.

LILLE, 10th April, 1888.

Textile Manufactures.—The Easter holidays, and the uncertain aspect of political affairs, have, as I predicted, occasioned a sensible retardation of business. The weather has changed for the better; but the sense of impending danger outweighs favourable influences of this sort. Events are constantly happening to remind traders of the instability of the situation, and with such a condition of affairs speculation cannot exist. Consumers limit their purchases to the bare needs of the moment, and business drags languidly along. The prospect is, therefore, gloomy and discouraging, notwithstanding the fact that all other conditions are favourable to a revival. Though the last week was characterised by dulness generaly, some improvement is noticeable in the woollen trade of the Roubaix district. A good numbers of buyers have visited the locality, and have bought largely. This revival is looked upon as the beginning of the spring trade. The goods most in demand are serges and corded fabrics. Fashion seems to be setting in the direction of mohair striped goods. The Lyons newspapers give glowing accounts of an invention which is said to have caused some stir among manufacturers of that locality. At one of the large weaving establishments a process is, it is said, in successful operation for the manufacture of metallic cloth—that is, cloth woven with wire thread. As trimmings this kind of goods is very effective.

Flax and Yarn Markets.—Last week was a quiet period for flax. Few transactions took place in home grown produce, and Russian was almost wholly neglected. Tows were bought in considerable quantities for export. The situation has not sensibly changed for linen yarns. Like all others, this market has felt the influence of the holiday season, and the political events of the last two weeks. Hemp shows some improvement.

The Iron Market.—The distinctive features of the iron market in this district are firmness and buoyancy of prices. The demand is not brisk; but manufacturers are determined to widen the margin for profits, and accordingly we hear of steadily advancing rates, from which no concession is made under any pretext. This attitude of the forge masters is much more conducive to life and activity in the market for finished goods than that of doubt and timidity taken up by the Paris merchants. The Syndical Chamber of Founders continues to obtain fresh adherents. It seems now certain that the project for syndicating the whole founding industry of the Nord will be carried into effect. The moment is opportune, for prices are but barely remunerative, and work is plentiful.

The Boulogne Fishing Industry.—The fishing industry of Boulogne, by far the most important in France, has been rapidly declining of late. The Government has resolved to establish at that port an "aquicultural station," with a view to check the evil. Under the management of Dr. H. E. Sauvage, this station will become a centre of technical instruction for fishermen.

MADRID, 9th April, 1888.

Shipbuilding.—No official announcement has been made as to the prices at which tenders have been made for the three cruisers of 7000 tons; but from what has transpired through the parties interested, it appears that the prices range from £480,000 to £620,000. Only three out of the nine tenders are supposed to comply with all the requirements laid down. As I have already said, it is most likely that the contract will be given to Señor Martinez de las Rivas, who is associated with Sir Charles Palmer. Their design is very good and complete, and they can establish the yard very quickly. The design of the Gironde Company is for a vessel 20 metres longer than Sir Charles Palmer's, and with the same displacement. By this means they expect to get the required speed with less powerful engines, but our naval authorities object to the length as being inconvenient. Tenders for three torpedo boats of 500 tons have been opened and publicly read. In this case the boats are to be built from designs made for Government by Señor Fallerie, a Spanish naval architect. The tenders varied from £90,000 by a new company at Corunna, to £120,000 by a Cadiz house. The lowest tender will probably be accepted if the company offers the necessary guarantee.

Electric Lighting.—The electric light is being introduced into Albacete, the capital of the province of the same name, for public lighting. Rules have been officially published for carrying out the order to introduce the electric light into all the theatres of this city within six months. The illuminated fountains at the Barcelona Exhibition are to be lighted by the Anglo-American Brush Corporation of London.

NEW YORK, 31st March, 1888.

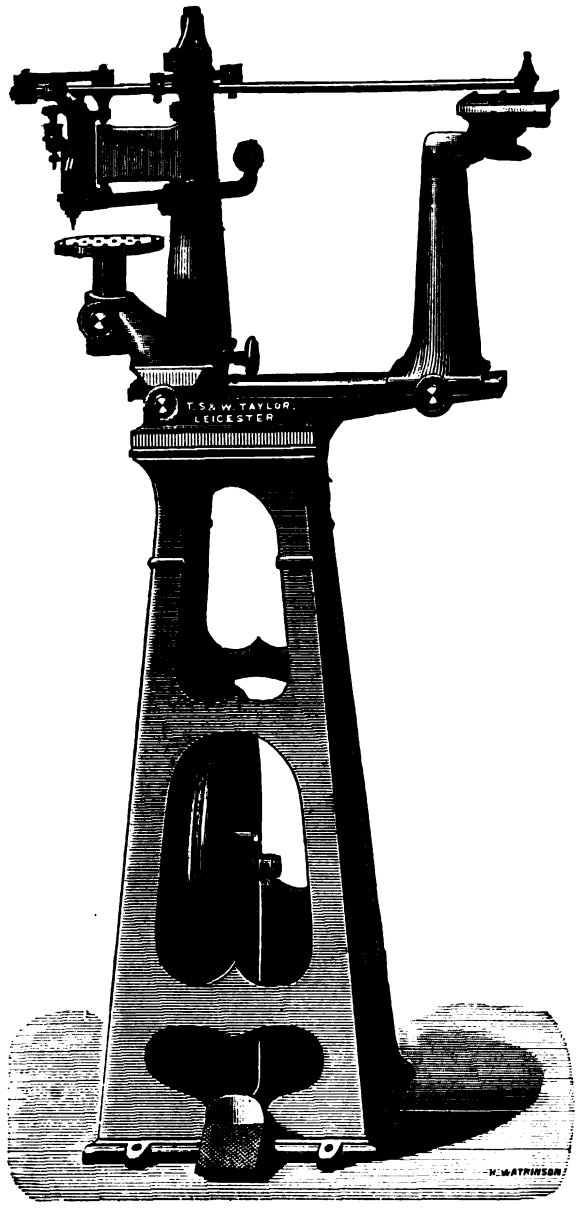
The Coal Market.—The anthracite coal trade is dull, and prices have weakened somewhat; but the larger companies are maintaining circular rates. Dealers expect that the opening of the spring trade will improve the outlook, but it is difficult for an outsider to see anything favourable in the situation; up to the present time only about two-thirds of the mines have been at work, and the demand has never exceeded the production. Nearly all the mines, however, will be working soon, and the output will be as large as last year unless some restriction is placed upon production.

The Iron and Steel Markets.—There is a better feeling in the pig iron market than for some time past. Good brands find a ready sale, and the lower grade stocks having been largely absorbed by pipe makers, prices are steady, although makers of finished iron want lower prices; but there is little chance of any material reduction at present. The output has been largely reduced, and as there are now no large stocks on hand the demand will probably keep pace with the supply, and enable makers to maintain their prices. On the 1st March there were 98 anthracite and 128 bituminous and coke furnaces in blast, with an output of 95,000 tons, against 287 furnaces last year, with an output of 123,000 tons. For January and February the production was 200,000 tons less this year than last, or a decrease at the rate of 1,200,000 tons for the year. There is nothing encouraging in the outlook for manufactured iron. A moderate number of new orders have been given out for bars, but at prices that can leave no profit to the sellers. A great many of the mills are on short time, and those which run full have seldom more than a couple of weeks' work ahead. While 1·9 cent to 1·95 cent per lb. are the nominal quotations, the great bulk of the business is at 1·85 cent to 1·9 cent, and even less, for best refined bars. There is a little better inquiry for plates, and a fair business has been done, but with no improvement in price; and at the existing rates for foreign material, there are no prospects of an advance in domestic prices at present. The Pittsburgh Tube Works have closed down indefinitely, because of the dulness of the trade and low prices. The Atlantic Iron and Nail Works at Sharon, and the Greenville Rolling Mill at Greenville, Pa., have also closed, throwing over eight hundred men out of employment. It is now over three months since the Edgar Thompson Steel Works and the blast furnaces of Carnegie Brothers & Co. closed down because of difficulties with their men. Four of their seven furnaces are banked, and three are blown out. Negotiations are being made for the men to resume work. There is a fair demand for steel rails, and sales in small lots are numerous. Prices are steadily maintained, with most of the sales at $32 per ton at the mill, although desirable orders can be placed at $31·50 to $31·75. The demand for Bessemer steel in other shapes is exceptionally large, so that the mills find themselves pretty well employed.

The Metal Markets.—Consumers are buying but little copper now, and all transactions are light. The reports of the Calumet and Hecla mine are still favourable, and as the temperature is falling, it is believed that the fire is out. The exports for the year have been moderate, amounting to about £24,000,000. Prices are a little better for future delivery, quotations being 16·10 cents for May, and 16 cents for June. The tin market has declined, prices having fallen from 35·70 cents to 30·80 cents per lb. for May, and 30·25 cents for June. The business in tin plates has slightly increased, but the unsettled condition of the tariff keeps the market uncertain. There has been a moderate speculative demand for lead, over 1000 tons having been dealt in. Consumers are backward in buying, and the market closed at 5·15 cents per lb. for April. Spelter is weak and dull; spot for common domestic is quoted at 5 cents to 5·10 cents per lb.

Incandescent Lamp.—The Westinghouse Electric Company have just completed an incandescent lamp which will last 2500 to 3000 hours, as against 800 to 1000 hours in the ordinary Edison lamp.

PHILADELPHIA, 31st March, 1888.



Sugar.—During the latter part of 1887 a sugar trust was formed among refiners, and all the refineries passed into the possession of the trust about the beginning of the year, the original owners receiving in return a certain amount of trust stock. There are four large refineries which have remained independent, and to a certain extent prevent the trust from completing their plans. Both the public and the producers of raw sugar feel the effects of this syndicate, the following being a fair example of how it is worked. On January 29th there arrived at New York a cargo of raw Manilla sugar amounting to 2100 tons. The cargo was sold in the usual way, at 4¼ cents per lb., to the only bidder. During the first week of the same month an almost identical cargo was sold at 4⅝ cents. During the same time the price of refined sugar had increased from below 6 cents to over 7½ cents per lb. This single transaction will net the trust nearly £16,000 over what the profits would have been if competition were free. There has been some talk of starting another independent refinery in this city, but the matter seems to have been dropped. Mr. Claus Spreckles has been in Philadelphia this last week, and talks of starting a refinery somewhere in the East; but as it would take a year and a half or two years to get it into operation, the prospect of lower prices in sugar by his efforts is rather slight, and it is probable that, if the trust will not disturb him in his own province west of the Mississippi, where he has practically a monopoly of the sugar trade, his visit East will have no good result.

Miners' Insurance.—The system of insurance in use among the Lehigh Coal and Navigation Company's mines in its practical working has been one of the most successful systems tried in this country. Each inside worker pays 1 per cent. of his earnings per month, and each outside worker ½ per cent.; but in no case are they allowed to pay over $1 per month. The company pays into the treasury of the relief association 1 cent per ton of coal mined. Allowances are paid to each workman who is prevented from working by accident, amounting to one-half the pay of the class to which he belongs; but the payment is stopped after six months. The death allowance amounts to $30 and half wages for one year. Owing to the prosperous condition of the treasury, the management has decided that hereafter half wages will be paid to a miner's family eighteen months after his death.

TAYLOR'S ENGRAVING MACHINE.

We illustrate herewith a neat little tool by means of which engraving work can be done quickly and at the same time with almost mathematical precision. The graver is a drill or chisel revolving at high speed, and carried over the surface to be engraved by the short arm of an ordinary pantograph, the long arm of which is provided with a stylus or "tracer," and guided by hand over the enlarged pattern of the letters, figures, or other devices to be copied. Owing to the reduction of movement much greater accuracy can be obtained than by hand work, and the cut is so sharp and clean that it is possible to engrave, without any previous lining out, metal surfaces after they have been lacquered. This is an advantage insuring a good finish, for where the work is first engraved and then lacquered, the lacquer is liable

to accumulate round the edges of the letters as the brush passes over them. The arms of the pantograph allow a reduction of one-third to one-sixteenth to be attained, and any error of the hand in guiding the tracer on the end of the longer arm is therefore reduced in the same proportion. The machine consists of a vertical stand, with treadle and fly wheel, from which passes a gut to an overhead shaft, whilst a second gut passes down from this shaft over guide pulleys to the vertical spindle carrying the graver. The latter may be pointed or provided with a broad edge, according to the kind of work required; but in all cases a horizontal cross section near the cutting edge is semi-circular in shape, the flat of the semi-circle passing through the axis of the spindle, and one of the edges is slightly more prominent than the other. The machine is provided with a V bed and two slide rests, one to take the pattern and the other the work. Where letters and figures have to be engraved the pattern letters are arranged after the manner of printers' type, and slipped into the grooves shown in our illustration at the top of the pattern table. The slide rest for the work is arranged to take horizontal, vertical, or inclined surface plates, to which the object to be engraved is secured. For mathematical dividing the work is secured to a circular dividing plate provided with worm gearing and vernier.

An important feature of this machine is the feed gear, to insure constant depth of cut. This is fixed to the left of the cutter spindle, and consists of two screw motions, the one to advance the cutter to the surface of the work, and the other, which is limited by an adjustable stop, to give the requisite depth of cut. The half round cutters are ground on the machine itself by means of an emery wheel which is fixed on the cutter spindle, whilst the cutter is set at the requisite angle horizontally in bearings placed on the circular plate and slowly revolved through less than a half turn, whilst the emery wheel is advanced against the point of the cutter. By limiting the rotation of the cutter to less than 180°, one of the cutting edges is left slightly more prominent. The machine can be used not only to cut letters and designs, but also for circular mathematical dividing, forming routing, recessing, &c. It is the invention of Mr. W. Taylor, of Leicester, and can be seen at work at the show rooms of the Britannia Company, 100, Houndsditch, London.

AN IMPROVED AIR PROPELLER.

The air propeller shown in our illustrations has just been introduced by the Union Engineering Company, of Manchester, successors to the late firm of Messrs. C. Schiele & Co., and makers of the Schiele fan. It is, therefore, not a matter of surprise that this firm, in constructing their new propeller, should have concluded to adopt certain curves for the blades which had already proved successful in other forms. The revolving blades A are contained in a short tube so arranged as to be readily

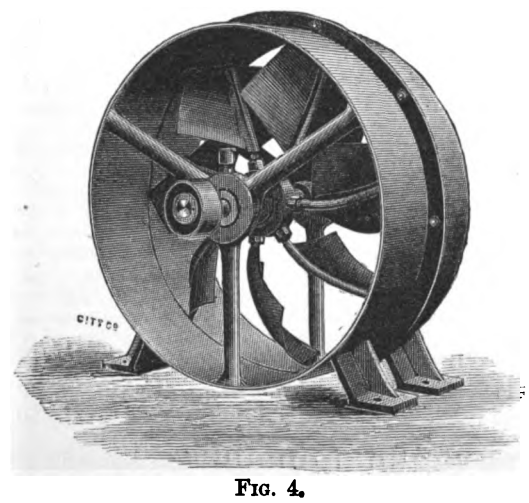

Fig. 4.

fixed in a wall or window as desired. The blades are carried on arms B, which are screwed into the boss, and, as will be seen, fastened securely by means of a lock nut. Contrary to the usual practice, the blades do not come right up to the centre, but are arranged to produce their operative effect nearer the inner circumference of the tube. Reference to Figs. 1, 2, 3, and 4 will give an accurate idea of the shape and curves of each blade, both the longitudinal and transverse sections being given. The propeller is driven with the concave side of the blades forward, the effect being that the air is drawn from the sides of the tube towards the centre, and there ejected. In this way the friction of the moving air is

AN IMPROVED AIR PROPELLER.

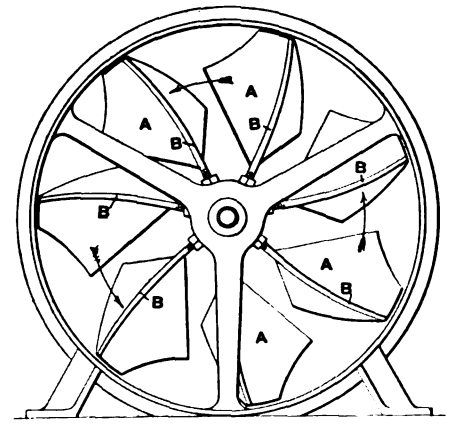

Fig. 1.

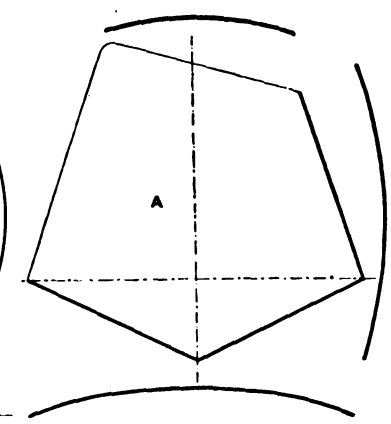

Fig. 2.

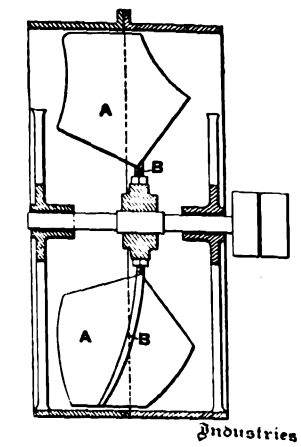

Fig. 3.

lessened, and the resistance from that cause diminished in proportion. The makers have made a series of experimental trials with a 36in. propeller, and state that, at a speed of six hundred revolutions per minute, 15,400 cub. ft. of air per minute was exhausted, and a partial vacuum set up, which registered 1½in. on the water gauge. The latter result is a valuable one, and is somewhat unusual so far as propellers are concerned. It overcomes the difficulty which is experienced whenever a strong wind is blowing against the face of some propellers, as no harmful effect is produced in this case. The whole of the bearings of the propeller are well arranged, and the machine is made in a thoroughly strong and satisfactory manner.

THE FORTH BRIDGE.

The twentieth quarterly report of inspection by Major General Hutchinson, R.E., and Major Marindin, C.M.G., R.E., of the works in progress for the construction of the bridge over the River Forth, states that the works have steadily advanced during the past quarter, and that the engineers state that, at the present rate of progress, which they anticipate no difficulty in maintaining, the bridge will be completed towards the end of next year.

Temporary Works.

Appliances connected with the erection of the cantilevers and internal viaduct continue to form the principal additions to plant. Among these are four double derrick cranes with detached winches. These are movable along the internal viaduct, and will be available for the erection of the latter, as well as of the bottom members and of other portions of the structure within reach.

Permanent Works.

South Queensferry.—*Main Piers.*—The riveting of the diagonal struts is now practically complete. The standards for the wind fence, and about one-third of the flooring plates, are fixed. On the southern portion of the cantilevers the bottom members of the first bay are completely built, and are riveted for 105ft. A large portion of the junctions with the bottom members of the first ties and second struts is erected and partially riveted. The vertical webs of the booms of the top members and the bracing between them are erected for 120ft., and the temporary columns for their support are nearly complete. The whole of the first ties are built. The girders of the internal viaduct are connected to their support at the first vertical ties, and are extended 50ft. beyond the latter. On the northern portion the bottom members of the first bay are completely built, and are riveted for 120ft.; with the exception of the lengths connecting them with the first ties and second struts, the junctions at their extremities are completely erected and the greater portion is riveted. The first bay of wind bracing between the bottom members, and three-quarters of the second bay, are in place. The vertical webs of the booms of the top members and the bracing between them are built out for a distance of 120ft., and the temporary columns for their support are in place. The whole of the first ties are built. The girders of the internal viaduct are extended to the same distance as on the southern portion. The riveted work at South Queensferry now amounts to about 5770 tons, an addition of about 890 tons during the quarter.

Cantilever and Viaduct Piers.—The masonry of the cantilever pier now stands at a level of 165·5ft. above O.D., and the centres of the arches of the masonry viaduct are in course of erection.

Inchgarvie.—*Main Piers.*—The junctions at the top of the vertical columns are complete, and also the top members. The riveting of the portion of the diagonal struts between their crossings and the top junctions has been commenced, and lengths of about 20ft. on each side are finished. On the southern portion of the cantilevers the bottom members are built out for about 156ft., and the first bay of wind bracing between them is riveted. The vertical webs of the booms and the bracing of the top members are built out for 40ft.; the first ties are built down for 45ft. The erecting platforms have been raised to their full height. The first struts are built to the level of 191ft. above O.D. The first vertical ties, with the bracing between them, and the support to the internal viaduct, are erected. Almost identical progress has been made on the

Digitized by Google

northern portions of the cantilevers as on the southern. The total amount of riveted steel work at Inchgarvie is 6977 tons, showing an addition of 1160 tons during the quarter.

North Queensferry.—*Main Piers.*—The riveting of the diagonal struts is now complete. On the southern portion of the cantilevers the bottom members of the first bay are completely built, and are riveted for 150ft.; with the exception of the lengths connecting them with the first ties and second struts, the junctions at their extremities are completely erected. The vertical webs of the booms, and the bracing of the top members, are built out for 125ft., and the temporary column for their support is in place. The first ties have been erected. The first struts are built to the level of 228ft. above O.D., and are riveted for 170ft.; the second bay of bracing between them is erected as far as the intersection. The girders of the internal viaduct have been connected to the support at the first vertical ties, and extended about 50ft. beyond the latter. On the northern portion the amount of work completed is almost identical with that on the southern portion. The total quantity of riveted steel work at North Queensferry is about 6382 tons, an increase of 975 tons during the quarter.

Cantilever and Viaduct Piers.—The masonry of the cantilever pier now stands at an average height of 172·5ft. above O.D.

General Remarks.

Masonry and Concrete.—Up to the present date 585,000 cub. ft. of granite have been delivered, and 569,320 cub. ft. have been set; and about 111,950 cub. yards of rubble masonry and concrete work have been built.

Steel Work.—*First Bays.*—With the exception of two bays of bracing between No. 1 struts, the whole of the steel for the bays has been drilled and fitted.

Second Bays.—All the main members, the supports at the centre of the bays, the internal viaduct, the bracing between the bottom members, about half the junctions, and the trestles at the end of the bays, have been drilled. The fitting of the bottom junctions, of the bracing between the bottom members, of the supports at the centres of the bays, and of the internal viaduct, is well advanced. The fitting of the top junctions has been commenced.

Third Bays.—With the exception of the struts for the Inchgarvie cantilevers, the whole of the main members, as well as a large portion of the bottom junctions and of the bracing between the bottom members, have been drilled. The fitting of the bottom members has been commenced.

Fourth Bays.—The whole of the bottom members and of the main ties, and about one-half of the struts and top members have been drilled.

Fifth Bays.—The main ties are drilled.

In all 48,300 tons of steel, an addition of 1560 tons since the date of the last report, have been delivered.

The weather in December was below the average, that of January fairly good, and in February it was similar to that of past years. The greatest wind pressures recorded were: 9lb. per square foot on the large gauge on 17th December; 16lb. per square foot on the small gauge on 5th January; 27lb. per square foot on the small revolving gauge on January 5th; 28lb. per square foot on the small gauge on North Queensferry platform on 5th January. The average number of men employed per diem during the quarter has been 3090, and the number employed on the 27th February was 2940.

The inspectors state that they see no falling off in the quality of the work or in the nature of the skilful appliances by which it is being carried on, and that it is also satisfactory to note that during the past quarter the serious accidents have been far less numerous than heretofore.

THE STEAM YACHT "WANDERER."

The yacht "Wanderer," which has been purchased by Prince Torlonia, of Rome, left this country for Italy in the beginning of this week. The "Wanderer" was built about ten years ago for her late owner—Mr. Charles Lambert, of Valparaiso and London—by the late firm Steel & Co., of Greenock. The "Wanderer" is a composite vessel of 730 tons, and is primarily a sailing ship. She is brigantine rigged, has a poop deck and topgallant forecastle, is fitted with an auxiliary feathering screw, carries a telescopic funnel, and in general appearance is more like an American war cruiser than a pleasure yacht. When the vessel was built, engines and boilers on Perkins' high pressure system were supplied; but after a very exhaustive series of trials, extending over more than a year, it was decided to abandon the high pressure plant. The extreme delicacy required in the management of the boilers, and the practical difficulties involved in the use of such high pressures in the engines, were disadvantages which more than balanced any gain in economy of space and fuel. The engines were therefore removed, and replaced by compound engines supplied with steam of 80lb. per sq. in. pressure, by two return tube boilers; the speed attained being 11 knots. The "Wanderer," which name has been translated into "Vagus," has been undergoing thorough refit at Cowes during the past few weeks. The cabins and saloons have been upholstered in the most luxurious manner; and the ship has been fitted with an unusually complete installation of electric light, consisting of boiler, direct driven dynamo, complete auxiliary condensing plant, accumulators—capacity 660 ampère hours—115 lamps throughout the ship, a gangway lamp of 200 c.p., and a search light. The contractors for the electric lighting plant were Messrs. Muir, Mavor, and Coulson, of Glasgow.

Notices of Meetings.

THIS WEEK.

Institution of Civil Engineers.—Friday, 13th April, 7-30 p.m. Students' meeting. Paper to be read on "Joy's Valve Gear Applied to Locomotives," by Mr. H. H. Carrick, Stud.Inst.C.E.

Physical Society.—Saturday, 14th April, 3 p.m. Papers to be read on "The Measurements of the e.m.f. of Dynamos," by Professor W. E. Ayrton, F.R.S., and Professor J. Perry, F.R.S.; "The Variation of the Co-Efficients of Inductions," by Mr. W. E. Sumpner, B.Sc.; "Some Experiments on Soap Bubbles," by Mr. C. V. Boys; and "Electromotive Forces by Contact," by Mr. C. D. Burton, B.Sc.

NEXT WEEK.

Society of Arts.—Monday, 16th April, 8 p.m. Cantor lecture on "Milk Supply, and Butter and Cheese Making," by Mr. Richard Bannister.—Tuesday, 17th April, 8 p.m. Foreign and Colonial Section. Paper to be read on "A Hundred Years' Progress in New South Wales," by Mr. W. F. Buchanan.—Wednesday, 18th April, 8 p.m. Ordinary meeting. Paper to be read on "Telescopes for Stellar Photographs," by Sir Howard Grubb, F.R.S.

Cleveland Institution of Engineers.—Monday, 16th April, 7-30 p.m. Discussion on the "Architects' Registration Bill," now before Parliament. Paper to be read on "The Stockton and Middlesbrough Corporations' Water Works," by Mr. D. D. Wilson, Middlesbrough.

Institution of Civil Engineers.—Tuesday, 17th April, 8 p.m. Ordinary meeting. Paper to be further discussed, "Compressed Oil Gas and its Applications," by Mr. Arthur Ayres, M.Inst.C.E. Paper to be read (time permitting) on "The Distribution of Hydraulic Power in London," by Mr. E. B. Ellington, M.Inst.C.E.

Royal Statistical Society.—Tuesday, 17th April, 7-45 p.m. Paper to be read on "Progressive Taxation: Some Examples from Switzerland," by Mr. R. H. J. Palgrave, F.R.S.

Meteorological Society.—Wednesday, 18th April, 7 p.m. Papers to be read on "Jordan's New Pattern Photographic Sunshine Recorder," by Mr. J. B. Jordan; "On the Meteorology of South-Eastern China in 1886," by Mr. W. Doberck, Ph.D., F.R.Met.Soc.; on "Lightning in Snowstorms," by Professor A. S. Herschel, M.A., F.R.S.; and on "Insolation," by Mr. R. T. Smith, M.Inst.C.E., F.R.Met.Soc.

Royal Institution of Great Britain.—Thursday, 19th April, 3 p.m. Lecture on "The Chemical Arts," by Professor Dewar.

Chemical Society.—Thursday, 19th April, 8 p.m. Ballot. Paper to be read on "Influence of Temperature on the Composition and Solubility of Hydrated Calcium Sulphate and of Calcium Hydroxide," by Messrs. W. A. Shenstone and J. T. Cundall.

PRICES CURRENT, 12th April.

Quotations at per ton, unless otherwise specified.

Messrs. Carrick & Brockbank, Manchester, report as follows:—

Copper.—The estimated visible supply, England and France, at beginning of year stood at 42,251 tons, and on 1st April the figures given are 58,880 tons, showing an increase during the past three months of 16,129 tons. Notwithstanding this increase, Chili bars continue to be quoted £80 to £80. 10s. for spot parcels, and for three months about 10s. per ton less; but there is no great amount of business reported. Manufactured is still without life; there is no buying except for pressing requirements.

Tin.—Straits spot parcels still quoted at £166 to £166. 10s. per ton; but forward deliveries range from £123 to £140 per ton, according to date. The visible supply on the 1st inst. was estimated at 12,513 tons more than on 1st April last year.

Lead is easier. Spanish quoted £14 to £14. 5s. per ton.

Spelter quiet and rather drooping.

HOME INDUSTRIES.

MANCHESTER, 12th April, 1888.

The Cotton Trade.—The past fortnight has witnessed a very small trade in yarns. There are offers in the market, but they are too low in price for acceptance. The general tendency is decidedly towards lower prices, and there is a little more inclination on the part of sellers to give way. At present the majority of spinners are at work on contracts which have some time to run, and in consequence the pressure to sell only comes from those who are not in such a fortunate position. The influence of the silver question on this market is forcibly illustrated by the fact that the fall in the price of exchange which took place last month was immediately succeeded by lower offers for yarn and cloth. The recent stocktakings show better results in most cases, and dividends are again being regularly paid. In the cloth market there has been comparative stagnation, with a decided tendency towards lower rates. Here again the fall in exchange has had its effect, for although there are orders in the market they cannot be placed except at much lower prices than most makers are prepared to accept.

The Silver Question.—During the past week an important conference of the Bimetallic League has been held in Manchester. Several papers were read propounding theories as to the evil consequences alleged to flow from the present monetary system.

Wages Disputes.—A strike of iron moulders has taken place in Manchester owing to a demand made by the workmen for an advance of 2s. per week. At present the employers do not propose as a body to grant the advance, although in one or two cases that course has already been taken. The men appear to have acted quite independently of the Central Association, and the strike does not affect machine making establishments. The spinners in the Oldham district have asked their employers for an advance of wages of 5 per cent., on the ground that the state of trade is now so much better that the reduction which was made in 1885 ought to be restored. A conference of both parties is to be held, at which the matter will be discussed with a view of arriving at a settlement.

New Engineering Ventures.—As has been previously briefly announced in these columns, the works erected by the late Mr. Evan Leigh, for the manufacture of cotton machinery, have, after many vicissitudes, passed into the hands of Mr. S. Brooks, of the Union Iron Works, Manchester. These works are intended to be used for the construction of carding and roving machinery exclusively, and will be carried on separately from the works at West Gorton. The carding engine to be made by Mr. Brooks is that which has been patented by Mr. F. Wilkinson, and has many points of novelty. The works are capable of employing six or seven hundred hands. Messrs. Blakey, Emmott, & Co., Limited, the well known electrical engineers of Halifax, have opened premises in King-street, Manchester, for the sale of a number of special engineering tools, many of which are admirably adapted for electrical work. The machines are mostly special, and many of them have from time to time been described in these columns.

New Ice Making Machine.—During the present week there has been exhibited here a new patent domestic ice making machine, which is of very neat and compact design, and embodies some important improvements. The machine is known as the "Zero" ice making machine, and is the joint invention of Messrs. Connacher & Williams. Its principal features consist of a double acting vacuum pump, an acid resisting enamelled iron absorbing vessel for containing sulphuric acid, and an automatic feed arrangement for admitting in small quantities the water to be frozen. The vacuum pump suction valves are worked in a positive manner, and the whole of the working parts of the pump are immersed in a bath of oil, so that the pump is self lubricating, and its friction is reduced to a minimum. As we hope to give a detailed description of the invention shortly, we need only add that the inventors claim that the machine will work effectively in any climate without the need of skilled attendance, and that in the smallest machine they make for domestic use 7lb. of ice can be produced at a cost of 1d.

LONDON, 12th April, 1888.

The Money Market.—The demand for money is by no means strong, and the market is well stocked with funds, so that rates are exceedingly easy, day-to-day loans being on offer at 1 per cent., while advances for longer periods are proportionally cheap. The stock markets are, generally speaking, quiet. There is little speculation, what there is of it being upon a modest scale in every respect. General Boulanger has supplied the disturbing element, without which the foreign department would hardly be recognisable; but on the whole foreign securities have shown themselves wonderfully firm. Turkish and Egyptian stocks have come in for a great deal of favour, which is partly due to the fact that they have without doubt been undervalued in the past. Egyptian Preferences are recommended as a good investment, and though Turkish credit is not likely to become established all at once in popular estimation, there is no doubt that it is fast improving. The growing favour bestowed on foreign investments which, a short time ago, would have been looked at askance, is further indicated by the remarkable rush for the new loans of Mexico and Uruguay. There is little business doing in home railways, which are strong, especially the Northern lines. American railways have not yet made any move towards improvement. There has been a revival of speculative activity in copper shares, and the diamond shares are still disturbed, though in neither is there the great rush of a few weeks back.

Companies.—Mr. Goschen's Budget proposal to tax the capital of new limited liability companies on their formation is causing a tremendous rush to be registered before this becomes law. Since our last report, the following new companies have been registered: Hollins Mill Company, Limited, with a capital of £76,000, to purchase a cotton mill; Smith & Wright, Limited, with a capital of £50,000, to manufacture buttons and ornaments; the Great Harwood Albert Mill Company, Limited, with a capital of £15,000; Armstrong Patent Glass Blowing Machines Syndicate, Limited, with a capital of £50,000; Tunbridge Wells Electric Light Company, Limited, with a capital of £30,000; Kensington and Knightsbridge Electric Lighting Company, Limited, with a capital of £250,000, to take over the business of the Kensington Court Electric Lighting Company, Limited, whose installation was described and illustrated in *Industries*, Vol. II., page 173, and Vol. IV., page 220; the Anglo-Pacific Steel Company, Limited, with a capital of £100,000, to purchase the businesses of an agricultural capital of £63,000; Edward Humphries, Limited, with a and general engineer and brick maker carried on at Pershore, Worcestershire, by the late Edward Humphries; the Vale Mill, Limited, with a capital of £3,000, to carry on the business of cotton manufacturers; Salvo Laundry Supply Company, Limited, with a capital of £100,000; the Cellular Clothing Company, Limited, with a capital of £25,000, to manufacture Kershaw's cellular cloth; Magee, Marshall, and Co., Limited, with a capital of £250,000, to carry on business at Bolton as brewers, &c.; Roberts, Buckley, and Co., Limited, with a capital of £10,000, to purchase the business carried on at the Queen-street Iron Works, Stalybridge; the Tyddynmawr and North Wales Exploration Gold Mining Company, Limited, with a capital of £30,000; the Victory Gold Mining Company, Limited (Venezuela), with a capital of £200,000; the Hawaiian Tramway Company, Limited, with a capital of £130,000; the W. R. Goodbody Sewing Machine Company, Limited, with a capital of £10,000; the Kempson Stopper Bottling and Brewery Company, Limited, with a capital of £100,000; the Anglo-Chilian Nitrate and Railway Company, Limited, with a capital of £500,000; New Zealand Beaches, Limited, with a capital of £50,000, to acquire grants of sea beach in New Zealand, and to explore the same for the discovery of gold or other metals by dredging or other means; Gold Fields of French Guayana, Limited, with a capital of £100,000; Pacific Mining Company, Limited (U.S.A.), with a capital of £675,000; Sparre Patents Company, Limited, with a capital of £400,000, to acquire patents relating to a machine for preparing cards used in Jacquard looms, a machine relating to such cards, a new system of making cartridges, a new system of making writing paper, and a new system of moulds affording protection against imitation of bank notes and securities; and the Indian Tramways Construction Company, Limited, with a capital of £80,000.

Textiles.—At the opening of the second series of the Colonial wool sales last week there was a good attendance of buyers, both the home and foreign trades being represented. The total available quantity is 340,000 bales, and 9495 bales are catalogued for this sale. Prices on the whole have been the same as were obtained during the latter part of the first series of sales. Stocks of Baltic hemp are at present low, but fresh arrivals are expected. The price for spot parcels remains firm. A fair business has been done in Manilla hemp for arrival, but prices have varied. Nothing is doing in Sisal hemp.

Shipping.—With the exception of American and homeward Indian freights, rates are firm. Business is dull in the Baltic and Mediterranean, but the rates are higher than last year.

Coal.—The total imports of coal into the port and district of London during March amounted to 419,784 tons by sea, and 712,553 tons by railway and canal, as compared with 390,819 tons and 669,297 tons respectively in the same month of last year. The total exports amounted to 300,820 tons, as compared with 265,133 tons in March last. The total increase in trade within the London district for the first quarter of this year is 159,689 tons.

The Navy.—H.M.S. "Victoria," built by Sir W. G. Armstrong & Co., arrived at Sheerness on Monday from Newcastle-on-Tyne, where she was delivered to the Medway Steam Reserve authorities, to be completed for active service.—Admiralty and Lloyd's scholarships for private students in naval architecture and marine engineering, of the annual value of £50 each, tenable for three years, are thrown open to competition, there being a vacancy for one of each class of scholarship. Applications have to be made not later than the 23rd May by letter, addressed to the Secretary of the Admiralty, Whitehall, S.W.—A report has been published of the Directors of Army and Navy Contracts on the subject of the publication of the prices of accepted tenders, in which they say that there can be no hesitation in recommending the continuance of the present practice of treating tenders as strictly confidential.

Railways.—The gross receipts of the twenty-three principal railways in the United Kingdom for the week ending 1st April amounted to £1,188,850 on 15,850¾ miles, as compared with £1,166,329 in the corresponding period of 1887, when the mileage was 15,708¾ miles. An increase is thus shown in the mileage of 142 miles, or 0·9 per cent., and in the receipts of 1·9 per cent. A new railway will shortly be completed between Barking and Pitsea, on the London, Tilbury, & Southend Railway, which will shorten the distance between London and Southend by about 20 per cent. It has been about two years under construction.

The Carroll Feed Water Purifier.—When describing this apparatus in our issue of the 30th of March, we omitted to mention that Messrs. Charles Appleby & Co., of London, are manufacturing these appliances on behalf of the limited company which has been formed to acquire the patent rights for Great Britain, &c. We understand that the company are in a position to grant licenses for the use of this invention, and applications should be addressed to the Secretary of the Carroll Boiler Water Purifier, Limited, 89, Cannon-street, London, E.C.

GLASGOW, 12th April, 1888.

Shipping.—It is reported that grain can be brought from New York to Glasgow for ½d. per bushel, and that it is being brought free as ballast to Liverpool. The outlook in the grain trade is far from promising.—It is reported that a quantity of German steel plates has been imported by a shipbuilding firm on the Clyde.—The s.s. "Anchoria," of the Anchor Line, has just made a very fast passage across the Atlantic. She left Sandy Hook at 10-30 on the morning of the 31st ult., and passed Tory Island at noon on the 9th inst., having made the passage in eight days twenty-one hours.—The failure of a large firm of marine insurance brokers has been the subject of much Exchange talk. A statement of affairs has been submitted, from which it would appear that on a favourable realisation of assets, a considerable surplus would accrue. From the statement made at the meeting of creditors, it seems that losses to the amount of upwards of £100,000 fell upon the firm last year. Glasgow underwriters are known to have suffered heavily during the past few years.

Shipbuilding.—Messrs. Scott & Co., of Greenock, have booked a contract for a screw steamer of 800 tons, with triple expansion engines of 650 h.p. The steamer is to be employed in the South American coasting trade. Messrs. W. Swan & Co., Maryhill, are about to build a small screw steamer for the West Indies. Messrs. Fisher & Co., Paisley, will supply the triple expansion engines.

Glasgow Corporation Stock.—One effect of the conversion scheme of the Chancellor of the Exchequer has naturally been to increase the demand for local loan stock, which offers a fair interest and first class security. This has been manifested in the result of the second issue of £115,000 of Glasgow Corporation 3¼ per cent. redeemable stock. Applications amounting to upwards of £540,000 were placed in the hands of the committee. The average price at which allotments were made was £101. 5s. to £101. 10s., or a premium of from 25s. to 30s. per cent.

Tenders Wanted.—Contracts are about to be placed for the following: Two steam dredgers and seven barges for the North Sea Canal; and a steel bridge to be erected over the Clyde.

International Exhibition.—The sections of the Exhibition are now being rapidly filled with exhibits, the last day for receiving exhibits, according to the original prospectus, being Saturday, the 14th inst. The Exhibition will be opened by the Prince of Wales on the 8th May. On the 21st April there will be a Press view, to which invitations will be issued to a great number of journalists from all parts of the kingdom. The fountains, the switchback, and other out-of-door attractions are in an advanced state of preparation. The electric light installation is approaching completion, and the boilers, flues, &c., are being pushed forward with all possible speed.

(From our own Correspondents.)

SHEFFIELD, 11th April, 1888.

The Heavy Industries.—Comparatively few complaints are now heard from manufacturers about the dulness of trade. There is no doubt that the improvement is sound, and is likely to last for some months to come. At the furnaces the output is increasing, and a good business is being done in the iron trade. Bars are quoted at £5. 5s., and plates at £6. 5s. per ton. A much better price is also being obtained for best sections of steel rails; and quotations for all descriptions of railway material are firmer. At the works of Messrs. T. Turton & Sons there is great activity on railway springs; Messrs. Steel, Tozer, and Messrs. Cammell & Co. continue busy on Bessemer rails for Continental and Colonial use; and other local firms engaged on railway work are well employed. Girders for bridges and roofing are also in extensive demand; and Messrs. Vickers & Sons have good orders on hand for shipbuilding material. One of Sheffield's best customers for railway material is India, to which a vast quantity of rolling stock is now being sent, and manufacturers are hoping that with the conquest of Burmah, and the demonstration in Thibet, there may be a considerable development ere long of railway enterprise on the borders of our Indian possessions. There is somewhat of a lull in armour plate making, and in the production of war material generally. Nearly all kinds of heavy machinery are in demand, and high pressure boilers are now selling readily. The engineers and machinists have been internally busy during the Easter time; many local works have been overhauling their plant, and proceeding with extensions and renewals. The agricultural implement trade, the stove grate, the edge tool, and the cutlery branches are all

Digitized by Google

yielding a satisfactory amount of work, and it is long since Sheffield hardware manufacturers and merchants were busier than now.

COAL.—At the South Yorkshire pits the demand for house and manufacturing coal shows slight diminution. The impression here is that the Midland Railway Company will yet succeed in taking over the Hull and Barnsley Railway at the terms offered, though the directors of the latter have declined the offer, preferring to have the opinion of the shareholders on the point. The project has aroused great interest not only among shareholders and coal owners, but among local manufacturers, for it is borne in mind that if the Midland obtain possession of this line, they will have, with the proposed link from Dore to Chinley, and on to Manchester, a through communication from sea to sea.

NORTH STAFFORDSHIRE, 11TH APRIL, 1888.

THE POTTERY TRADE.—Orders are rather more numerous, and on the average prices somewhat improved. Several large orders have recently been taken in this district from American buyers, and altogether there prevails a more satisfactory tone in the trade. The demand for manufacturing fuel is on the increase, at prices ruling from 7s. to 8s. at the pit, according to quality.

NORTH STAFFORDSHIRE COAL AND IRON MASTERS' ASSOCIATION.—The quarterly meeting of this Association was held at Stoke, on Monday last, Mr. Robert Heath, jun., in the chair. There was a fair attendance of members. The Bills now before Parliament for amending the Employers' Liability Act, 1880, were carefully discussed. Members felt with regard to trade that the future was uncertain, but no appreciable improvement was anticipated until the autumn. Sales were generally deferred until the quarterly meeting at Birmingham, to-morrow (Thursday). Since the January meeting two new blast furnaces have been blown in, one by the Chatterley Iron Company, and one by Earl Granville. There are now twenty-one in blast out of the thirty-nine in existence.

ENGINEERING.—Trade is very slack at the local foundries, and engineers complain bitterly of the prices which prevail. Ordinary castings can be obtained at little over £3 per ton, a price which leaves no margin for profit. Foundry pig iron is selling at about 38s. 6d. for No. 3, and 40s. for No. 1, into truck at works.

COAL MINES REGULATION ACT.—The special rules for the district, framed in accordance with the new Act, will shortly be obtainable from Mr. Knight, secretary to the Coal and Iron Masters' Association. As managers carry the provisions of the Act into force they find a considerable addition to the cost of production, which, in the aggregate, is estimated at 5 per cent.

BIRMINGHAM, 11TH APRIL, 1888.

THE IRON TRADE.—In this trade things continue in much the same condition as in the last report, but there is on the whole a rather better feeling prevailing. The downward tendency seems at length to have ceased, and now that the Easter holidays are over, and stocks have to a certain extent been diminished, the markets are ruling a little firmer. Marked bars remain at £7, and unmarked at £5 to £5. 10s. There is a fair demand for constructive iron work, chiefly owing to activity in railway matters in India and the Colonies. In the galvanising trade business might be brisker; the makers are standing out for rather higher prices than buyers care to give, and this is causing slackness of work in some of the mills. Galvanised sheets of 24 gauge are from £11 upwards. Advices from Australia report a rather slow market for this class of goods. There is a fair inquiry for pig iron. Staffordshire hot blast brings 50s. to 52s. 6d.; medium, 40s.; and cinder, 30s. The steel trade continues active.

THE HARDWARE TRADE.—The home trade is suffering from the untoward character of the weather, but export business is looking up as is natural at this season. Agricultural implements are in good request for the various agricultural countries and Colonies. Makers of metal fittings and requisites for ships are well employed. Jewellers, and especially silver smiths and electro-platers, are fairly well off for orders, but nickel makers are far from satisfied. Concerning the formation of a syndicate in the latter trade nothing further has transpired, although a few weeks ago it was considered certain that something of the kind would be attempted.

LEICESTER, 11TH APRIL, 1888.

WOOL SPINNING AND YARN TRADES.—No very decided movement has taken place in the wool market during the past fortnight. There is no greater amount of business being done, and prices are much as they were. Though growers are now more disposed to clear at a fractional decrease, yet country dealers are tolerably firm. The firmness of rates at the London wool sales has not, as was expected, very beneficially affected the local market. Spinners are only buying to supply their immediate wants. Orders are not numerous, nor for large amounts, whilst the prices which are quoted are barely remunerative. Yarn merchants are not doing much, and the uncertainty of prices militates greatly against the transaction of business.

HOSIERY TRADE.—General dissatisfaction prevails as to the present state of business. The trade is not up to the average, and the keen competition allows very narrow margins of profit. The trade is not prosperous either in the fancy or plain departments, and some of the houses have been heavily handicapped by several failures.

BOOT AND SHOE TRADE.—This year so far has been one in which trade has been much below the average. The usual heavy demand experienced before Easter has not been felt this year, and all orders were easily filled. Buyers are extremely reluctant to operate, and then only at prices which are cut down as low as possible. Orders coming in are only for unsatisfactory amounts, and it is not easy to keep the hands fully employed. There is but little doing in the leather market, and prices are ruling very low.

BARROW-IN-FURNESS, 11TH APRIL, 1888.

WOOD PULP WORKS.—The initial steps which have been taken at Barrow in the boring operations for water supply, preparatory to laying down large works for the manufacture on a large scale of wood pulp for paper making, have so far been very successful. A bore hole has been sunk about 200 yards through red sandstone, with the result that a considerable supply of water has already been secured. A much larger hole will now be sunk, and it is confidently expected that as the question of an adequate supply of water has been definitely solved, no difficulty will be experienced in proceeding with the undertaking.

NEW BOILER WORKS.—Messrs. Westray & Copeland, engineers and iron founders, of Barrow, who have lately developed a marine engineering trade, are now engaged in building a new boiler works of considerable size, and it is expected, as their establishment is in close proximity to the docks and the graving docks, they will be able to furnish themselves with plenty of work in this new branch of their business.

IRON AND STEEL TRADES.—There is a steady tone in the hematite pig iron trade, and orders are offering briskly, prices being steady for Bessemer in mixed numbers at 43s. 6d. to 44s. per ton net f.o.b., and 42s. 6d. to 43s. for forge and foundry qualities. There is a growing demand on foreign and Colonial account, but not much outlook from America. There is briskness in the steel trade in every department. The output of rails is maintained at its maximum, and orders are freely offering. Prices, however, do not move upwards, and are now quoted at £3. 10s. 6d. to £4 per ton. Shipbuilding material is steady at £6. 19s. for plates, and £6. 9s. for angles. A good trade is doing in billets at £3. 17s. 6d., and a quiet trade in nail slabs at £3. 16s. Blooms are in better inquiry at £3. 16s. per ton. Wire rods, however, have declined, and are at £5. 7s. 6d. for No. 5 standard. Iron ore is quiet; but the deliveries are fully maintained on old contracts, prices ranging from 8s. 6d. to 11s. 6d per ton net at mines. Spiegeleisen, which is largely consumed in the district, is quoted at £3. 15s. per ton net f.o.b. for 20 per cent. quality.

MIDDLESBROUGH, 11TH APRIL, 1888.

PIG IRON.—There is a growing conviction that, considering the state of business generally, and the large continued decrease in iron stocks, prices cannot remain long as they are. They have indeed begun to move, and No. 3 is quoted at from 31s. 9d. to 32s. for prompt delivery, and 32s. to 32s. 6d. for forward for No. 3 G.M.B. In warrants Connal's No. 3 is quoted at 31s. 10d. per ton cash, and Connal's hematite at 42s. 6d. to 43s. Makers' brands (East Coast) are 43s. to 43s. 6d. The shipments of pig iron still continue very favourable, having amounted to 23,836 tons up to the 9th of the current month, as compared with 18,516 tons to the 9th of April, 1887. The shipments for the first quarter of the year ending March 31st amounted to 207,555 tons, as compared with 172,388 tons during the first quarter of 1887. The increase is both in foreign and coastwise shipments, but chiefly in the foreign. The usual quarterly meeting of the North of England iron trade was held yesterday upon 'Change.

MANUFACTURED IRON AND STEEL.—There is no change in these trades, and all the works promptly resumed after the holidays. In the steel trade heavy rails are readily taken at £3. 15s. The shipments of manufactured iron and steel for the first quarter of the year showed a marked improvement over that of the corresponding quarter last year, being 126,989, against 104,467 tons. A curious claim by the East Indian Government has cropped up in the course of their shipments, viz., that stores going out to the East Indian Government railways should be free from all dock and harbour dues, so far as docks and harbours which had incorporated the Harbours, Docks, and Piers Clauses Act of 1847. The argument is that railway materials are Government stores virtually when they are wanted for the East Indian railways, which belong to the Government. Such a claim if pressed will tell heavily upon such bodies as the Tees Commission and the Clyde Trust. Both these bodies are resisting it.

COAL AND COKE.—Both these industries are active, and prices are well maintained. During the first quarter of the year the export of coal coastwise has rather fallen off as compared with last year, but the export of coke has improved. The export of coal abroad is much about the same, but that of coke has decidedly improved. There is an increase in the over-sea exports in the value of goods other than coal and coke of £98,908.

NEWCASTLE, 11TH APRIL, 1888.

H.M.S. "VICTORIA."—The armour clad "Victoria," which has been built by Messrs. Armstrong, Mitchell, & Co., proceeded to Chatham from Newcastle on the 8th inst. Her chief dimensions are: Length, 340ft.; beam, 70ft.; mean draught, 26ft. 9in.; displacement, 10,500 tons, and the power of her engines is 12,000 i.h.p. The armanent consists of two guns of 110 tons each, and of 16¼in. calibre, as well as one 11in. gun of 30 tons, and twelve 6in. 5-ton broadside guns, &c. The turret in which the 110-ton guns are to be placed is covered with bound steel armour 17in. thick. The guns will fire a projectile of 1800lb. weight, with a charge of gunpowder weighing 960lb. The vessel is lighted throughout by electricity; the same means will be used for firing the guns, while the loading of the latter will be effected by hydraulic mechanism. The propelling power consists of twin screws of 16ft. diam., each of which is driven by triple expansion engines, with 43in., 62in., and 96in. cylinders, and 51in. stroke. There is accommodation for a storage of 1200 tons of coal, which is sufficient to carry the vessel at its maximum speed of 16¾ knots through a distance of 1600 nautical miles. For protection against heavy projectiles a belt of armour 18in. thick extends 3ft. or 4ft. above and below the water line, 152ft. in length, on each side of the vessel; and ample magazine accommodation is obtained in the internal part of the ship, on account of her great beam, so that for the 110-ton guns she will be able to carry 160 rounds of projectile and powder.

ROPE WORKS.—In addition to the important local orders that are now in the hands of rope manufacturers, some good export contracts have been secured, and the very ample resources of the various factories are being fully utilised. The demand for the different descriptions of wire rope is not only maintained, but is increasing, and the heavier sizes of hemp rope are also in fair request.

GLASS WORKS.—In the pressed glass trade business is very brisk, the requirements of jam manufacturers and other users of pressed glass goods being at this season unusually urgent. The makers of paraffin lamp chimneys, however, are becoming slack, and the operatives are now generally on short time. In the stained glass branch, activity is still the feature; and manufacturers of polished plate glass are extremely busy.

LEATHER WORKS.—In the leather trade, the demand for ordinary qualities is somewhat limited; but inquiries for special descriptions are numerous. The foreign demand for india-rubber goods has rather improved, and Messrs. George Angus & Co. are preparing to make some heavy shipments next week.

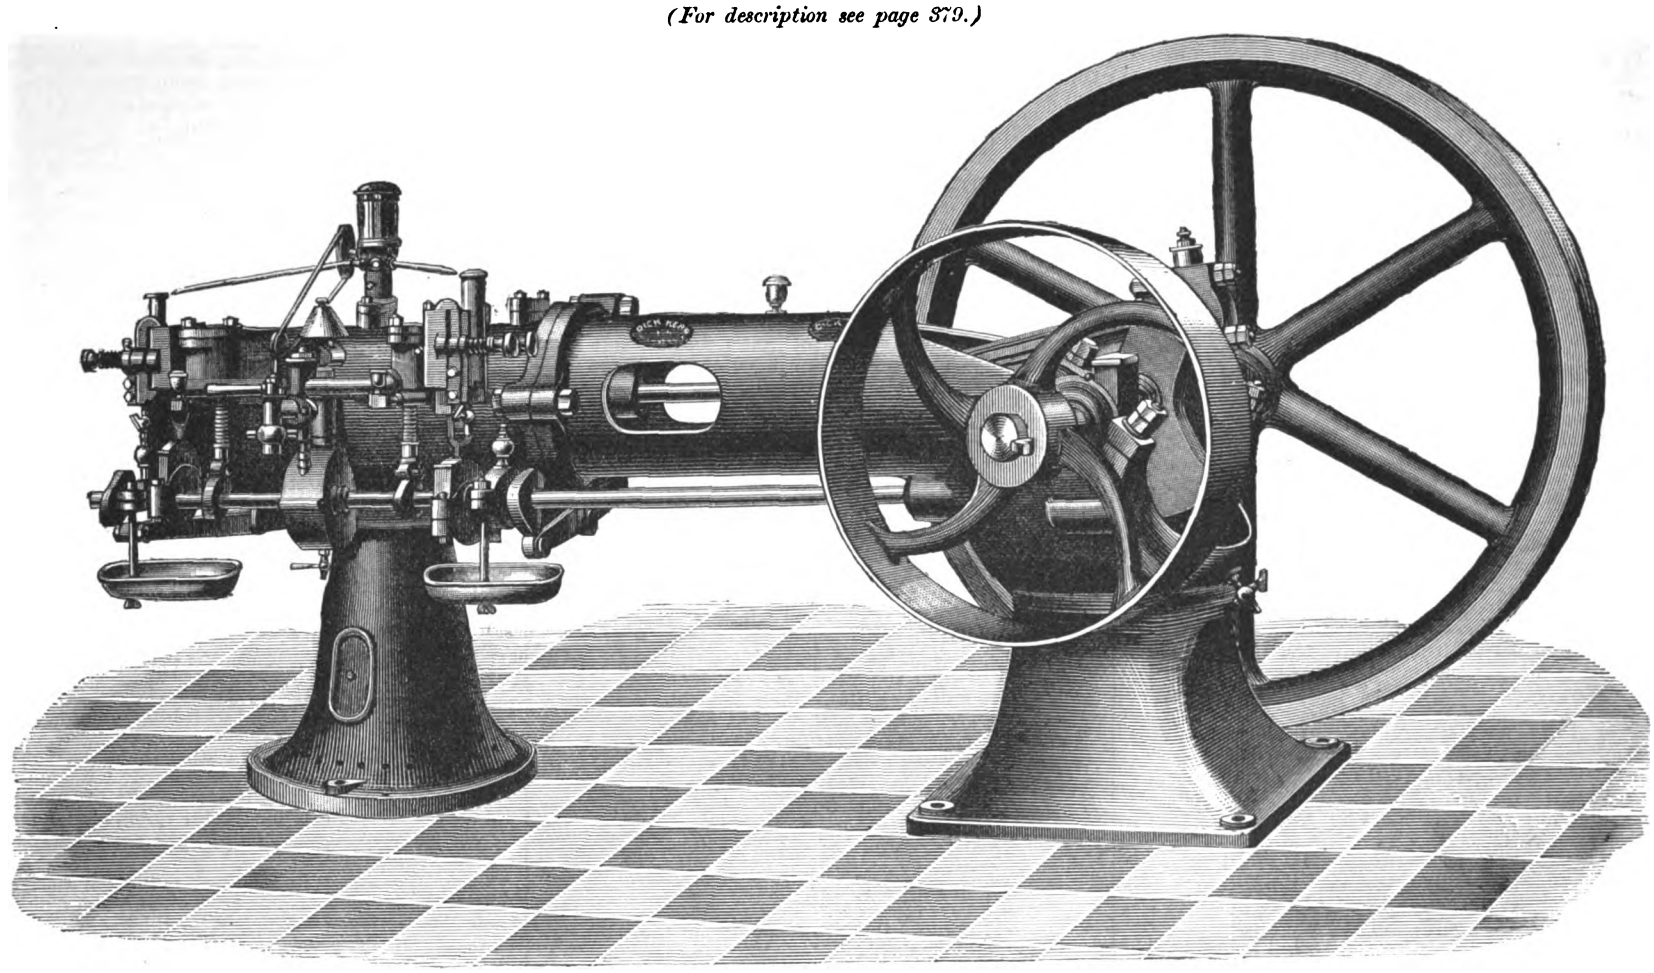
WIRE WORKS.—Wire workers are much busier than they were at the opening of the year, the demand for those descriptions of wire goods which are used in the preparation of fire clay having been considerably stimulated of late. There is also a good demand for the wire cloth used in connection with paper manufacture, and the consumption of goods required for gardening and agricultural purposes is steadily increasing.

FIRE BRICKS, &C.—In the fire brick and sanitary pipe trade considerable animation now exists, and large quantities of both kinds of goods are being shipped, in fulfilment of foreign orders.

PAPER WORKS.—Paper manufacturers are decidedly busy, the local demand being of itself almost sufficient to keep the machinery in steady operation.

THE COAL TRADE.—The Northumberland coal trade, which has been exceedingly dull throughout the winter, is now, through the re-opening of the Baltic ports, likely to regain some of its former activity. Prices of steam coals are already beginning to show an upward tendency, and there is no doubt whatever that an increasing demand will very shortly cause increased employment at the pits. The shipments of coals and coke from Tyne Dock for the week ending April 7th, amounted to 83,864 tons, being an increase of 8421 tons over the shipments for the corresponding week in 1887.

LAUNCH.—On the 4th inst. there was launched from the yard of Mr. J. T. Eltringham, South Shields, a paddle steamer, built to the order of Messrs. J. P. Rennoldson and Co. (who supply the engines, &c.), for Messrs. Martin and Marquand, Cardiff. The vessel is 122ft. long by 20ft. wide, and 11ft. deep. She is named "The Earl of Dunraven," and is intended for the passenger trade in the Bristol Channel.



DUNDEE, 11TH APRIL, 1888.

FLAX AND JUTE TRADES.—The staple industries of the town and district have undergone little change during the last fortnight. Buyers show little disposition to extend their purchases beyond the supply of their immediate wants. Flax on the spot has sold to a moderate extent for assortment purposes. In view of the early opening of the Baltic ports spinners are not disposed to purchase largely. Few sales on contract have been reported. Exchange still shows an upward tendency, and prices here are consequently firmer. Flax yarns have been moderately dealt in at late prices, and where slight concessions are made by spinners, manufacturers operate more freely. There is still a want of life in the local linen trade; but in the Fife district manufacturers of fine goods are fairly well employed. The demand for sailcloth is quiet, and the prices are unchanged. Jute on the spot is in fair demand, at full rates. Jute yarns do not move off so freely, and although quotations are maintained, a slight concession might be made to effect sales. In jute fabrics hessians are in quiet demand, the orders being barely sufficient to take off the production, and quotations are weak in consequence. There is still a fairly active demand for bagging, but sacking and tarpaulin are in rather less request.

THE "GRIFFIN" GAS ENGINE.

(For description see page 379.)

THE CARDON FLAX SCUTCHING MACHINE.

A short time ago we gave (see *Industries*, Vol. III., page 387) an illustrated description of the improved Cardon scutching machine, patented first in France, and brought to Belfast in the early part of last year. This machine, from the reports which had preceded it to this country, was expected to revolutionise the preparatory methods of separating the straw from the fibre, and by giving a greater yield out of the same weight of material, the cost of linen goods was to be reduced about 40 per cent. This opinion was not, as one might now suppose, merely a bait thrown out by the inventor to attract attention, nor even that of some persons with only a theoretical knowledge of the machine, but it was the true and conscientious opinion formed by practical men connected with flax manufactories, and also by the representatives of machine making firms in the United Kingdom. Prior to the introduction of the Cardon machine, no mechanical appliance or arrangement which had been introduced combined, with any degree of success, the two processes of crushing and scutching the flax straw. The objections which prevented all or any from being generally adopted when brought to actual test, were due to some one or more of the three following causes: (1) To their price being too great, which placed them beyond the reach of poor farmers, who are, as might be expected, unable to afford large sums for a machine which can only be used during a few months of each year; (2) to their productive capacities being too limited; and (3) to their action being too rough and injurious to the fibre. In flax scutching mills, both at home and abroad, the general system of crushing flax is to pass the stalks through one, two, or three pairs of iron fluted rollers in a loose condition. The crushed straw is then carried to the scutchers, who separate it into small bundles, and by holding these up against the blows of revolving wooden blades the core becomes broken into particles and knocked out, and the fibre freed from over 60 per cent. of unworkable matter. This process is necessarily slow, tedious, and not very satisfactory; but its great recommendation is that the first cost for fitting up a mill complete for the purpose is very small, and suits the limited means of the farmers, who can seldom afford to pay say £150 for each machine required, although even promised that this amount would be saved in wages after five years' work. Again, any machines which have been tested were only competent to manipulate about 600lb. or 800lb. of material per day.

Taking all these facts into consideration, M. Cardon realised that he could only hope to get his machine adopted by having it introduced into spinning factories, and the work carried out there instead of at the growing districts. He therefore invited inspection by manufacturers, and so satisfactory did the results appear to be, that information was at once dispatched to England on the subject. After several inquiries, representatives of several of our machine making firms were at once dispatched to Lille, where the machine was to be seen at work; and their report being satisfactory, a deputation of specialists from the North of Ireland followed suit, and after a careful inspection of its working, extending over several days, they returned home, and described it in terms of laudatory commendation, which even the inventor would have failed to surpass. Some further negotiations then took place between Messrs. Combe, Barbour, & Combe, machinists, Belfast, and the inventor, after which this firm were induced to purchase, at a considerable cost, the patent rights for the United Kingdom. No sooner was this agreement effected than several orders for the machines were placed in the makers' hands, and operations for making them were immediately commenced. When the first order was completed, and the machines fitted up, the straw was placed in holders, and—in the presence of a large number of specialists—introduced to the channel, through which it was conducted in satisfactory style between the crushers and beaters, after which it was delivered at the opposite end. On inspection, however, the fibre, although fairly well operated upon, was found to be rather inferior to what was expected. Among the orders placed for the machines was one by the Milfort Spinning and Weaving Company, Belfast, for two pairs, the price to be £400 each. This firm had them fitted up when completed in the best possible manner, so as to give every facility for doing good work: but when the first test was made, the result was found to be less encouraging than had been anticipated. The overlookers of this firm then decided to make an effort to improve the machines in their apparently defective points, and so perseveringly did they attach themselves to the work, that ultimately they felt justified in obtaining several patents for important improvements and additions. During the past year, the Cardon machines, although recognised to be partial failures, have been kept at work, in the hope of something being accomplished which would render them sufficiently profitable to return some part of the great outlay, but without avail, and they have now been stopped and are about to be discarded. Thus all the castles built in the air by those concerns enterprising enough to order the machines, have fallen to the ground. How our practical manufacturers could have been deceived to such an extent it is difficult to understand, as every test was conducted in a fair and apparently straightforward manner in France. From the great loss incurred, however, one good result has been obtained, viz., that it has now become fully recognised that the operations of crushing and scutching, whether conducted separately or in combination, must be left to the farmers.

Any machine which may be invented for this purpose must possess the following characteristics in order to insure success: (1) It must be cheap, the price not to exceed £60 for each machine; (2) if the "holder" system be adopted, a pair of scutchers must be capable of operating upon nearly 1000lb. of material per day; (3) each machine (or pair of machines, as the case may be) should only require the labour of not more than two attendants; (4) the working parts should be few and not liable to get out of order; (5) it is absolutely essential that both the crushing and scutching operations (by whatever means or methods they may be accomplished) should be combined in the same machine; (6) its principle should be such that while effectually separating the fibre from the wood, the former should on no account become broken or ruptured; and (7) the yield of fibre must not be less than 22 per cent.

The object is one well worthy of study and attention, and should be accomplished in one way or another in the near future. That such a machine would benefit the flax trade to a great extent, goes without saying; but it would also probably bring fame and wealth to the inventor. The obstacles in the way of success are no doubt difficult to surmount, chiefly on account of the great length of the flax fibre, which causes it to be so easily cut or broken, and to the fact that it adheres very firmly to the straw. The object, however, can, we believe, be accomplished, and our principal aim in making this reference to Cardon's machine is to give the question publicity, for we consider that flax machinery has not received a fraction of the attention which has been given by mechanical engineers to the machinery used in the manufacture of cotton. That the Cardon machine is an absolute failure is now beyond dispute; but its advent, although costing a few Irish spinners and machine makers probably £10,000, has been the means of directing a large share of public attention to the probability of a successful combination for mechanically separating the straw from the fibre.

Advertisements intended for insertion in the current week's issue must reach the Manchester Offices not later than first mail delivery on Thursday morning. Scale of charges for displayed advertisements on cover and inside pages will be forwarded on application. Orders for single advertisements must be accompanied by payment in order to insure insertion, the charge for which is 2s. 6d. for the first four lines or under, and 8d. for each additional line; one inch and over at 7s. per inch; the line averages eight words. While all practical regularity in the insertion of serial advertisements will be observed, it can only be absolutely guaranteed in the case of those ordered to appear weekly.

All accounts are payable to the Publisher, JAMES F. BUTTERWORTH, *70, Market-Street, Manchester. Cheques should be crossed Manchester and Liverpool District Bank, King-street Branch, Manchester. Post Office Orders to be made payable at Manchester.*

From July, 1886, to December, 1887.

A few Copies, handsomely bound in half calf, gilt lettered, may now be had at the Head Office, 70, Market-street, Manchester, Price 20s. each.

Industries:

FRIDAY, 13TH APRIL, 1888.

NEW MARKETS FOR BRITISH MANUFACTURES.

THERE are two questions which are constantly being debated among men who are engaged in industry and commerce, but which, owing to their speculative character, are extremely difficult of solution. The first question is whether England is being beaten in the competition for the markets of the world by any other nation; the second is whether these markets are likely, in the future, to provide for any such development of our industry and trade as we have witnessed in the past. These questions embrace the sum and substance of the future of British trade, and are therefore at all times seasonable; but they have been invested within the last two or three weeks with a certain amount of additional prominence by reason of the publication of several official documents, viz.: (1) The "statistical abstract of the principal and other foreign countries," issued by the Board of Trade; (2) the "report on the external commerce of the United States during the year 1887," issued by the Treasury Department at Washington; and (3) the "report on the foreign trade of the United Kingdom," prepared by Mr. Giffen, of the Board of Trade. With these and other official data at command, we may be able to throw some light upon the present circumstances and future prospects of British trade.

Probably the first fact that will strike the inquirer into the general course of the commerce of the world, during the last few years, is the comparative stagnation that has been equally a characteristic of all industrial countries, so far as their foreign trade is concerned. It is not easy to illustrate this satisfactorily by any sets of figures applying to the same years, or to the same commodities, because each country is liable to be affected by circumstances peculiar to itself, and by special circumstances in special years; but the broad general fact may be sufficiently exemplified by comparing the export returns of the principal countries over an interval of ten years, taking the two terminal years 1877 and 1886 for comparison, and 1880 as a year of comparatively good trade. The results compare thus:—

Value of Total Exports from Different Countries in Different Years (1=1000).

	1877. £	1880. £	1886. £
United Kingdom	252,316	286,414	268,667
Germany	138,120	218,070	219,230
France	174,832	184,492	169,836
Italy	40,896	47,248	42,775
Austria-Hungary	88,068	84,787	82,396
Russia	52,794	49,867	48,848
Belgium	80,471	89,006	100,485
Spain	20,554	25,489	27,529
Holland	44,151	52,062	78,962
United States	125,515	174,091	141,568

It is evident from these figures that the depression within the last few years has been general. There has not in all cases been an absolute decline; but there has been a cessation of progress which tells much the same tale. Some writers have endeavoured to draw a distinction between machine using and hand labour countries, and have endeavoured to establish the proposition that only the former have been depressed. It is a difficult matter to institute a fair comparison between countries where the resources of civilisation are all but unknown, and countries in which the highest triumphs of civilisation have been achieved. For the present purpose, however, such a comparison is not required. We cannot say with precision what is the economic condition of the kingdom of Abyssinia, for example, because there are no available records to throw light upon the subject. What does concern us to know is that the decline of business, or the very serious depression of prices, which we have so keenly felt in Great Britain for some years previous to 1887, has been quite general among the countries that have dealings with the rest of mankind. It has not, therefore, been our fate to suffer alone, and, so far, this is satisfactory, showing that relatively to their competitors British manufacturers and traders have retained their hold over the chief outside markets, besides our own Colonies. But there are important markets in which Germany, or France, or both, by virtue of their geographical position and trade connections, have made serious encroachments upon our former supremacy. In Russia, Norway, Sweden, Denmark, Holland, and Switzerland, Germany has a considerably larger share of the import trade than our own country. The following figures show the proportions of the trade of those countries which the two rivals had in each of the years 1877 and 1886:—

(1 = 1000.)

	Imports received from United Kingdom. 1877. £	1886. £	Imports received from Germany. 1877. £	1886. £
Russia	16,156	10,800	26,313	13,516
Norway	2,775	1,915	2,907	2,113
Sweden	4,850	4,700	3,742	5,600
Denmark	2,675	3,009	4,720	5,200
Holland	17,150	21,853	16,200	26,200
Switzerland	—	1,824	—	10,447
Totals	43,606	44,101	53,882	63,076

Germany shows in this table to advantage. She has improved her relative superiority, and at the later year was about nineteen millions better than the United Kingdom. But even Germany has not had it all to her liking in markets that nature appears to have intended to make peculiarly her own, and the falling off in her trade with Russia is specially suggestive. The broad general conclusion that follows from the analyses of our foreign trade here set forth is that Germany has no special advantage over the United Kingdom that is sufficient to give her precedence or pre-eminence in the new markets which are every day being opened up in different parts of the world by the discoveries and pioneer labours of geographers and commercial agents, by conquest and annexation, by the development of trading facilities, and by the constantly increasing wants of mankind; and if we are free from fear from Germany, we certainly need be in no great concern about any other industrial rival at present. All other Continental countries, except France and Belgium, are at present barely able to meet their own needs, and as regards these two countries, it is to be observed that while France has dearer labour, higher railway rates, and more limited industrial resources than either Germany or Belgium, the Belgians are prohibited by their limited number, and the necessarily restricted extent of their industries, from pushing us very closely in any except a few special trades.

When we inquire into the character of the demand that is likely to come from new markets that are either at present in course of development, or likely before long to be developed, the first consideration forced upon us is the great diversity that exists between different countries in the consumption of

Digitized by Google

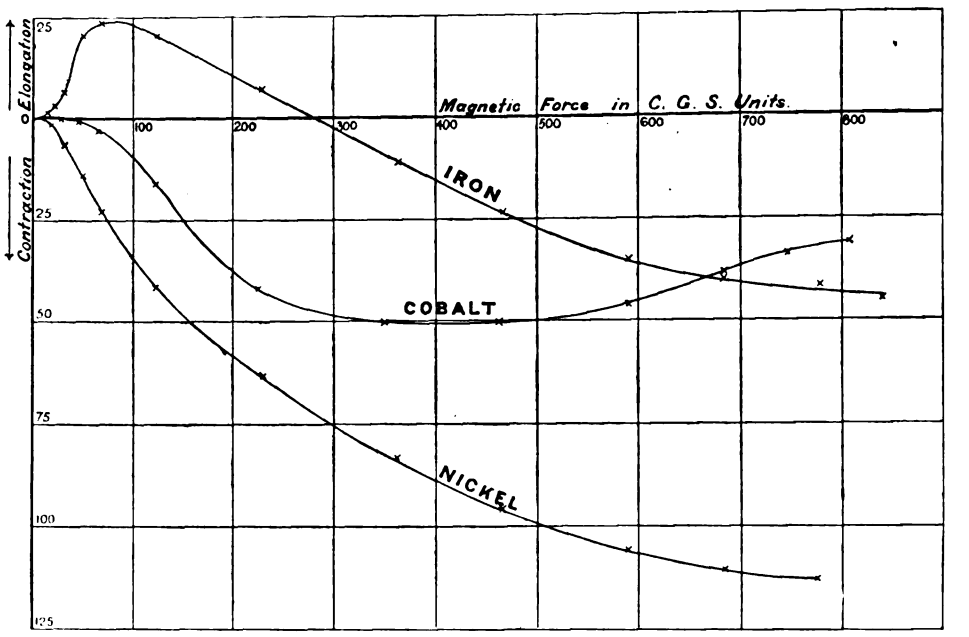
manufactured commodities, and this diversity is so remarkable that it is quite impossible to argue from the experience of any one country what the demands of another are likely to be, even as regards the essentials of food and clothing, and much less so as regards commodities of which the consumption is necessarily varied according to the special conditions of each country. Take, for example, the items of cotton and wool among commodities that are so-called necessaries of life. The consumption of these is higher in the United States than in the United Kingdom, and higher in the United Kingdom than in Germany or France. Take, again, the consumption of iron, which in the United States is twice the *per capita* average of Great Britain, and in Great Britain is twice the *per capita* average of other European countries. The present annual production of pig iron is roughly 21 millions of tons, and of this quantity fully one-third is consumed in the United States, giving an average *per capita* consumption of 260lb. Assume the population of the world to be 1200 millions, and the quantity of iron consumed, if the general average were the same as the particular average of the United States, would be not 21 millions of tons, as at present, but 140 millions of tons, or nearly seven times as much. Iron may appear to be an isolated case, but there are many commodities of which it may be regarded as the proxy and representative, and the consumption of which must eventually increase in similar proportions. The question for the British manufacturer is what countries are most likely to bring about this increased consumption. The three great future fields for the enterprise and occupation of the commercial nations of the world are China, Japan, and Burmah in Asia; the Congo Free State and Abyssinia in Africa; and the various Republics of South and Central America on the Continent of that name. If measured by population alone, the most important market of the future should be China, which has a population variously estimated at 350 to 430 millions, or between one-third and one-fourth of the total population of the world. There is, however, at present less to hope from China than from some other and more progressive countries. It is true that in China a beginning has actually been made with railway construction; but it is only a beginning, and in spite of the approval of the authorities, and the encouragement of many outside friends and advisers, the people are slow to adopt improvements. Moreover, the Chinese intend to develop their industries independently of other nations; they will endeavour to establish engine factories, iron and steel works, and other requirements in their own country, to be carried on by Chinese workmen, to the advantage of Chinese capital and labour. As a national programme this is no doubt excellent; but the Chinese are unacquainted with Western arts and sciences, and if they are to do everything for themselves, their progress must necessarily be very slow. However this may be, China is not at present making great demands upon the commerce of Europe, having in 1886 and three previous years imported less than in the four years ending 1880. Nor can we say much more for Japan, which stands in quite a different rank as regards the characteristics of the people and their desire for advancement, seeing that the value of the imports into Japan were less in 1886 than in 1880. Burmah, on the other hand, is lying at our feet, and if we can only take steps to develop its vast resources we shall undoubtedly reap a rich reward. Recent reports state that Upper Burmah, and the Chinese provinces on its borders, contain a population of 112 millions of people, or, roughly, twice the population of the United States, which is at present hardly touched by our commerce. In United Burmah there is room for an additional population of 80 millions; but in order to create the development of population and commerce, railways are urgently required. It has been established by Messrs. Holt, Hallett, and Colquhoun, that a system of railways between South-Western China and the Burmese littoral could be constructed cheaply—about £5,000 per mile for the greater part of the distance,—and that it would be likely to pay. But they think that the Government should guarantee the line. This is just what the Government do not show any inclination to do; and meanwhile France is endeavouring, from her coign of vantage in Indo-China, to secure the trade of Southern China, Siam, and the Shan States, by connecting them with her ports by railways. Here is one of the gravest perils to which the commerce of Great Britain is at the present time exposed. Once let England secure the possession of the chief means of communication between Upper Burmah, and Indo-China, Siam, and all the adjoining States, and we should enter into the enjoyment of a practical monopoly in one of the most promising fields in the world for trade and commerce. The wealth of this territory has been described by its most recent explorers as "incalculable," but "it lies fallow at present for want of communications, both internal and with the outer world." Already we have in India 268,000,000 of fellow subjects. Add the population that would be brought within the reach of our commercial intercourse by the development of this territory, and we should have at least 112,000,000 more ready and eager to receive our merchandise. British India now takes exports of British produce to the value of about £33,000,000 a year. Since 1872 the export trade with British India has, on an average, increased by a million sterling per annum—that is, from 18,000,000 to 33,000,000. But India is poor by comparison with some of these adjoining States; and if the commerce of these States were developed we should not have to wait long for results. The first thing to be done is to open up railway communication. At the present time all merchandise has to be carried over the very primitive roads of the country, at a cost of from ten to twelve times as much as if carried by rail. This, of course, renders business on a large scale impossible. But railway enterprise does not appear sufficiently promising to attract private capital. What, then, is to be done? Is it not reasonable to ask the Government to give a guarantee of interest on the cost of construction? A 3 per cent. guarantee would secure all the capital required within twenty-four hours, and the risk would be infinitesimal. In China and Burmah we have not, as in Africa, to deal with a population of savages having few wants, but with races "for the most part energetic, sober, hardy, clothes wearing, tool using, trade loving, and industrious;" and in those countries, if anywhere, is a field for British industry and trade.

THE BELL TELEPHONE BEFORE THE AMERICAN COURTS.

One of the most important patent cases on record has been decided at Washington by the Supreme Court of the United States on the 19th of last month. The question on which the Court had to give an opinion was nothing less than the validity of Graham Bell's telephone patents, about which numerous litigations in inferior Courts had previously taken place. In some of these cases appeals were made, and the Supreme Court had to deal with five of these, viz.: Amos E. Dolbear, the Molecular Telephone Company, the Clay Commercial Telephone Company, the People's Telephone Company, the Overland Telephone Company, and a cross appeal in the case of the Molecular Telephone Company. The judgment of the Court was in all cases in favour of the American Bell Telephone Company, who own the Bell patents; but three justices dissented from the finding of the Court in the matter of the appeal of the People's Telephone Company, who own the Drawbaugh patents. The opinion which was written by the Chief Justice is a very lengthy document, containing many elaborate arguments, lengthy quotations from newspapers and other sources, and reads like a counsel's brief for Bell. Some portions of the opinion are of a decidedly sensational character, such, for instance, as the argument in which the Chief Justice dismisses as unfounded the allegation that Bell's patent agent altered Bell's application after it had been filed by interpolating a part of Elisha Gray's claims relating to his variable resistance method. This charge is of such a remarkable nature that it reads almost like a portion of the Arabian Nights; the actual wording in the counsel's brief is "that Mr. Bell's attorneys had an underground railroad in operation between their office and Examiner Wilber's room in the Patent Office, by which they were enabled to have unlawful and guilty knowledge of Gray's papers, as soon as they were filed in the Patent Office; and that an important invention and a claim therefor were bodily interpolated into Bell's specification between February 14th, 1876, and February 19th, 1876, by Pollok, in consequence of the guilty knowledge which the latter already had of the contents of Gray's caveat before the declaration of interference with Gray on February 19th."

The argument of the Chief Justice may be divided into two parts: the first dealing with matters of fact, viz., as to whether Reis, Van der Weyde, McDonough, and Varley had anticipated Bell, and the second with a matter of conjecture, viz., whether he had been anticipated by Drawbaugh. Only circumstantial evidence was forthcoming in the latter case, which presents some peculiar features. Daniel Drawbaugh claims that he invented the telephone years before Bell or anyone else made one, and that, being only a poor mechanic, he was unable to push his invention in the market. His experiments are stated to have extended from 1862 to 1878, and it is asserted that a number of persons saw the instruments in practical operation from 1870 up to 1874. The Chief Justice points out that all that any of the witnesses could say on the subject was that they had used instruments in Drawbaugh's shop, and heard sounds and sometimes words spoken to them, and that Drawbaugh told them the sound was carried on the wire by electricity; but no one could say how the instruments were originally constructed, or what the process was by which the sound was transmitted. Stress is also laid on the fact that Drawbaugh visited the Centennial Exhibition at Philadelphia in 1876, at which Bell's instrument was on view; but seemed to have lost all interest in the subject, spoke to no one as to what he had done, and made no special effort to find out whether what was exhibited resembled his own invention. The conclusion arrived at is that though Drawbaugh may have conceived the idea that speech could be transmitted to a distance by means of electricity, and may have experimented on the subject, he did not discover how to do it before Bell did. The evidence of the seventy witnesses called in connection with this portion of the case seems to have been very inconclusive, for the three dissenting justices are led by it to an exactly opposite opinion. They believe that "this obscure mechanic did do the thing, and that he is entitled to the merit of being the first inventor." With regard to anticipation by other inventors, there was no difference of opinion between the judges. They one and all declare that neither Reis nor Bourseul, nor any of the other early pioneers in telephony, can be considered to have really anticipated Bell. The judges considered that the question was not whether the apparatus devised by Reis can with our present knowledge be made to transmit speech, but whether Reis had in his time found out a way of using it successfully for that purpose, and they are of opinion that Bell's patent would be just as good if Bell had actually used the Reis apparatus in developing the process for which the patent was granted. The point of difference between the inventions of Reis and Bell is that the former aimed at using intermittent currents, whilst the latter used a current of an undulatory nature. Van der Weyde is said to have simply copied Reis, and not to have produced a speaking telephone until Bell had taught him how to do it; and as regards McDonough, the fact of the American Patent Office refusing him a patent proves that he was anticipated by Reis. Varley's patents referred to an electric telegraph, and are, therefore, not considered to be anticipations of Bell. In this way all the claimants for priority are dismissed, and the Bell patent holds the field.

THE BUDGET DEBATE.



The Budget resolutions were passed on Monday evening "without amendment and without division." This was certainly due to the statement by the Chancellor of the Exchequer that the Government regarded their proposals as a whole, and would have all or none. The first Budget of Mr. Goschen exhibited several features questionable from the point of view of sound finance, and the second undoubtedly contains some provisions not quite consistent with sound principles of taxation. The relief of taxation by reducing the sum payable for the redemption of debt was the feature of the first, and the second might, perhaps, be characterised as a scheme for unloading the income tax and loading horses and carts. One of the cardinal principles of taxation is that "the tax ought to be so contrived as both to take out and to keep out of the pockets of the people as little as possible, over and above what it brings into the treasury." All experience goes to prove that the expense of collecting a number of small taxes is proportionally much greater than that of a single large tax. The cart tax will yield, according to Mr. Goschen's estimate, only £300,000, a sum which could have been raised by a fractional increase distributed over existing burdens without inventing a special tax to raise

Digitized by Google

it. This proposal thus infringes the canon of taxation quoted. The cart tax, besides, clearly tends "to obstruct the industry of the people, and to discourage them from applying to certain branches of business." So far as Adam Smith's authority goes, therefore, he is distinctly against the tax. It is in effect a return on a paltry scale to the numerous and vexatious petty taxes that obstructed industry up till within the past half century, during which the tendency has been to consolidate taxation, and to strike off insignificant and expensive sources of revenue. The debate was largely deprived of interest, because it was felt that no criticism would have any effect upon the homogeneous proposals of Mr. Goschen. With his usual astuteness, he was doubtless aware of the weakness of his case if it were attacked in detail, and he realised that its strength lay in a policy of insisting upon the Budget and the whole Budget.

There was truth, though only partial truth, in the statement which several speakers made from the Opposition benches, that the landlords and the richer classes were unduly favoured in the Budget proposals. So far as the contribution to local rates is concerned, it is not quite correct to say that the landlords and the landlords alone will benefit. While it is hard to determine with precision the person upon whom any particular tax actually falls, it is fairly clear that the person who pays the bulk of local rates in rural districts is the tenant farmer, and not the landlord. On the average, the farms are let at a sum above strict economic rent, so that taxes are paid by the tenant not out of what would otherwise necessarily go to the landlord as rent, but what would otherwise, other things being equal, go to himself as profit. Individual cases may of course exist in which the conditions are different from those pre-supposed; but, speaking generally, the tax is paid now by the tenant, and a reduction would, for a time at any rate, benefit him. In urban districts, the conditions are practically the same—the saved rate will go, in the first instance, to the manufacturer, and not to the landlord. The smallness of a local rate may of course act as an advantage of situation, and thus enable a landlord to gain a part of the saving as rent; but this is a remote effect of which the Chancellor of the Exchequer is not bound to take cognisance, since reduction upon any tax might similarly be absorbed, and would thus be open to the same objection. One item in the Budget proposals received comparatively slight attention in the debate. This was the proposal to impose an *ad valorem* tax of £1 per £1,000 of nominal capital on the registration of limited liability companies. Mr. Goschen estimates from this source a revenue of £110,000, calculated upon an annual registration of companies having an aggregate of £110,000,000 of nominal capital. Such a tax has long been advocated by the authorities at Somerset House. It has been felt that limited liability companies receive from the Legislature a protection which the private trader does not receive. Limited companies are liable to their creditors in the last event only to a fixed amount, and not to the extent of the aggregate means of the partners, as in a private concern. For this privilege, it is felt, the limited companies ought to pay. The amount fixed by the Budget proposal is not an excessive one, and is calculable as a legitimate part of the establishment expenses of a limited concern. Mr. Goschen attacked share holding at another point, and on this head he met with some criticism in the course of the debate. His proposal involves the fixing of a stamp of the value of sixpence to each contract note above £100, and from this he estimates a return of £50,000. One of his critics suggested a stamp of one penny per £100 upon all transactions on the stock exchange. There is something to be said for this second proposal, since such a tax would be certain to hit speculators much more heavily than investors. As it is, the stamp duty of Mr. Goschen may not fall upon the client in many cases, but will fall upon the broker. In the case of small transactions, the broker may charge it; but in the case of large transactions, the broker will almost certainly pay it himself. Trifling as the amount is, it thus hits the wrong person; and since it does not apply to speculative transactions in minerals and produce, it does not hit quite fairly. Re-adjustment of the incidence of taxation is a supremely difficult task, partly because of the noise which each attacked interest makes, when it is strong enough to be heard, and mainly because of the impossibility under ordinary conditions of devising a system by which an equitable distribution of burdens may be made. Mr. Goschen's Budget, sound enough in parts, as, for example, in its insistence of payment for the service rendered to the limited liability companies by the State, is to a great extent retrogressive, since it multiplies taxes without correspondingly increasing the equitable distribution of the burden of taxation. The inroads made upon Mr. Goschen's original figures by the provisions of the Local Government Bill, and the handing over to the new County Councils of some taxes now carried to Imperial credit, were properly but slightly discussed in the debate. These belong rather to discussion of the Bill of which practically they form a part.

THE ELONGATION AND CONTRACTION OF METALS IN MAGNETIC FIELDS.

THE ELONGATION AND CONTRACTION OF METALS IN MAGNETIC FIELDS.

It has long been known that a bar of iron when magnetised by a surrounding solenoid alters its length, and with the weak magnetising forces which were originally employed in these experiments, the alteration was invariably an increase in length. One of the earliest experimenters, and probably the original discoverer of this behaviour of iron when magnetised, was Joule; but he invariably found that the length increases with the magnetising force. In his experiments, however, the magnetising force did not exceed 87 C.G.S. units, and an ingenious theory was propounded to show that elongation must take place when a bar of iron is magnetised. It was believed that the molecules as they rotate under the influence of the lines of force, and become more or less parallel, they naturally require more room in the direction of the length of the rod, and therefore cause the latter to extend with a corresponding decrease of diameter. This simple explanation was refuted by the experiments of Mr. Shelford Bidwell, which he made some years ago, and in a paper communicated by him to the Royal Society in 1885, he showed that the elongation does not remain unchanged at its maximum when the magnetising force exceeds that which is sufficient to produce so-called saturation; but, on the contrary, that with increasing magnetising forces beyond this limit the elongation becomes less until the rod, after returning to its original length, ultimately becomes actually shorter than it was in the unmagnetised condition. Mr. Shelford Bidwell has, however, recently contributed to the Royal Society, another paper on the same subject, and in this he points out that his original investigations might be open to the following objections: (1) The field due to the magnetising solenoid was not quite uniform; (2) the effect of the ends of the rods was uncertain, and might have played some material part in the production of the phenomena in question; (3) all the rods used in the experiments retained a certain amount of permanent magnetism. To meet these objections he has carried out a further series of experiments by using rings instead of rods of iron, and observing the changes of diameter. The rings were also demagnetised before every observation, and the battery employed was much stronger than that used in the first experiments, so as to produce very great magnetising forces. He found that in their general character the phenomena of elongation and contraction were the same with rings and with straight bars, thus proving that the effect of magnetisation was independent of the form of the iron, and as it was much easier to obtain intense fields with straight than with circular solenoids, the author made some further experiments with straight rods. These experiments embraced iron, cobalt, nickel, manganese steel, and bismuth, and the highest magnetising force reached was 840 C.G.S. units. We are able, by the courtesy of Mr. Shelford Bidwell, to publish herewith a diagram showing the behaviour of iron, cobalt, and nickel in magnetic fields of varying intensity. The strength of field is plotted on the horizontal, and the change of length in ten millionths of the original length of the rod is plotted on the vertical, the elongations being plotted above, and contractions below, the axis. The line of bismuth, which metal was tested in fields varying from 500 to 840 units, almost coincides with the axis, and manganese steel was also found to be almost unaffected, the elongation in a field of 850 units being only about one-fifty millionth of the length. That the change of length in the other metals which are sensibly affected by magnetisation cannot be due to the mechanical stress produced by magnetic attraction between the ends of the bar, is shown by the author in the case of iron where mechanical stress does not account for more than one-fifth part of the observed magnetic contraction. It should also be remembered that up to a magnetising force of 280 units, iron elongates, and, therefore, the mechanical stress in iron opposes magnetic extension.

THE LIABILITY OF MINE OWNERS.

In reviewing the incidence of mining legislation, we have, in previous issues, pointed out that some provisions for making employers pecuniarily liable for certain classes of accidents, is a necessary corollary of the working of the Mines Regulation Act, and the present system of inspection. The question of the extension of this liability is one of the most difficult problems of the day. On the one hand, there exists abundant proof that, through low prices, increased cost of production due to legislative enactments, and heavy railway and royalty charges, colliery proprietors already experience the greatest difficulty in obtaining any return for the enormous capital invested in mines; and, on the other hand, although it can be shown that the relative earning powers of labour are increasing, miners' delegates are demanding the amendment of the Act of 1880 in many important features. We think, however, that conclusive evidence of the want of change should be forthcoming before any further burden is imposed by the Legislature upon an industry, in the conduct of which the Mines' Regulation Bill, passed by Parliament last session, has been found in practice to increase the cost of getting minerals in many districts by as much as 5 per cent. Pending the production of such evidence, the Bill to amend the Employers' Liability Act, 1880, brought in by Messrs. Burt, Broadhurst, and other labour representatives, ought to be condemned. By its provisions the maximum compensation recoverable by a workman is raised to £500, the negligence of any person in the service of the employer is sufficient to establish a claim, and contracting out of the Act under any circumstances is practically declared illegal. With the more moderate Bill of Mr. Secretary Matthews before the House, it may be taken for granted that this somewhat drastic measure will not be sanctioned by Parliament. The Bill introduced by the Home Secretary is to stand as a complete measure on this subject, and provides for the repeal of the Act of 1880. As some fundamental alterations in the law appear to be required, this probably is the best course to pursue, as unnecessary complications in its application are thereby avoided. The main points of difference between the provisions of this Bill and the Act now in operation consist of an amplification of the grounds upon which, and a simplification of the conditions as to notice, &c., under which, a workman is entitled to recover compensation for accident; in affect-

Digitized by Google

ing the usual common law form of defence, in defining more clearly the relative liability of employers and contractors or sub-contractors, and in legalising contraction out of the Act in accordance with the recommendation of the Select Committee of the House of Commons which sat in 1886—provided a benefit equivalent to the compensation recoverable under this Act is insured to the workmen out of a fund mutually subscribed to by employers and employed, but having regard to the "whole scope of the indemnity given and the proportion borne by the number of accidents in case of which the employer is liable to pay compensation under this Act, to the number of accidents which are the subject of insurance." The amount of compensation recoverable for an injury sustained by a workman shall not exceed the average earnings for the three previous years of a person in a similar grade of employment, or £150, as a maximum. The provisions of the measure are extended to injuries sustained by seamen in course of their employment on British ships. If passed into law the Act will come into operation on the 1st of January, 1889, and we recommend a more detailed consideration of its provisions to those particularly affected by the working of this measure, because, though conceived in a comparatively moderate spirit, it will certainly enhance the liability of employers, and make the not always desirable or beneficial machinery of litigation more accessible to workmen.

Letters to the Editor.

REGISTRATION OF ENGINEMEN.

To the Editor of "Industries."

Sir,—The official report No. 250, of which an abstract is given in your last week's issue, forms, I think, a good argument in support of Mr. Powis Bale's recent advocacy of the registration of enginemen. As the stupidity and ignorance of the engineman in question did not result in any serious accident, we can afford to smile over the report. It is obvious that a man who will adjust the load on the safety valve as he thinks fit, and test the saltness of the water by throwing a potato into it, is not a suitable person to be put in command of a boiler.

Yours, &c.,

Manchester, 9th April, 1888. Looker-on.

ON THE COST OF CENTRAL STATION LIGHTING.

To the Editor of "Industries."

Sir,—In a short letter, which you published on the 23rd March, I drew attention to some errors in the article by Mr. Crompton, which appeared in your issue of the 16th ult. The comparison drawn by him between the two rival systems, designated as the B.T. or battery transformer, and the A.T. or alternating transformer systems respectively, seems to show that of two installations, similar in regard to output and area supplied, based on the two methods of supply named, the prime cost is almost identically the same. If this were the case, and if the cost of maintenance of the two supply systems under consideration were also equal, I believe that the B.T. system might fairly claim to have a decided superiority over its rival, mainly from the fact that storage forms an important feature. That the first cost of the two systems is equal, and that the annual cost of maintenance is fairly comparable, I do not admit, and I will consequently endeavour to show what an ideal installation, such as taken by Mr. Crompton, would cost for construction and maintenance; leaving it to the advocates of the B.T. system to show that their method of supply is equally economical.

Before going into details it would, however, be well to make some further remarks regarding the feasibility and practical value of an undertaking carried out on the lines suggested by Mr. Crompton. No one will admit sooner than I, that a system in which storage is possible has an advantage over any other dependent entirely upon the producing machinery; but what I deny is that the problem of electric storage, suitable for the purposes of a general supply, and capable of being commercially maintained, has yet been solved, and that it is in a chemical contrivance that a solution of the difficulty is to be sought. Every system has its merits and advantages, and just as I would never contemplate employing transformers in a building where the lights are to be within a moderate distance of the producing plant, so would I consider inadvisable and out of place the use of storage batteries supplied direct from dynamos for electrical distribution on a large scale. Let me here enumerate my objections to the principle of the B.T. system for the purpose under consideration. (1) Secondary batteries have but a low efficiency, very low as compared with alternating transformers. (2) The cost of their maintenance is very great, quite out of comparison with that of transformers. (3) They require a great deal of attention; each cell has to be kept in order, and to be tested and examined, I may say daily, if it is to be kept in proper condition. (4) Every cell in a battery forms an important link in the series, and if anything goes wrong with one, it destroys the continuity of the whole series, and requires to be cut out and another put in its place. (5) The circuit of which the battery forms part is, after all, but a liquid circuit, possessing an infinity of joints all more or less imperfect, and liable to go wrong at any moment. (6) High insulation from earth on a circuit of which batteries form part is altogether out of the question, and leakage to earth on a line carrying a high potential is dangerous, and thus the limit of potential is soon reached at which it is practicable to work batteries. (7) In order to keep cells in working order, and each and every cell up to a proper standard condition, more charging must be given to some than to others, and this increases considerably the amount of attention required. (8) Cells designed for a given rate of discharge, if worked over this amount, are almost sure to be affected injuriously, and it is impossible to foretell exactly what the maximum discharge for a central supply station will be. The process of charging must of necessity be slow, as a large ampère current cannot be used if the source of supply be at a distance, and therefore the generating plant must be kept at work for a longer time than would be otherwise necessary. In fact, objections to the direct employment of batteries are numerous, and the difficulty lies in selecting those which are most forcible.

What now are the objections that may be fairly raised against the A.T. system? (1) The distribution of motive power is by this means not feasible at present; but that fault will, I believe, be remedied before long, as a means will be found for making an alternating current motor practicable and efficient. (2) The maximum output which may be required from the generating station at any moment must be provided for by the erection of the necessary producing plant in the first instance, and therefore the amount expended upon running machinery must be greater than would be the case in a storage system. (3) If an accident arises to the producing plant, as may easily happen whilst it is at work, part of the area supplied with electricity is left unprovided for and in darkness. (4) Arc lights worked by alternating currents are unsatisfactory. (5) Great difficulty exists in the maintenance of proper insulation when conductors carrying high potentials have to be placed underground. (6) Accidents may easily occur through the high potential of the primary breaking down the insulation in the transformers, finding its way to lamp circuit and to earth.

That other objections to the employment of the A.T. system exist in the minds of its opponents I have no doubt, but I believe the above list includes all which are important. Against these objections may be set advantages which will counterbalance, if not altogether do away with them. The second and third objections I have named are not so formidable as would appear at first sight, if the units of the producing plant at the supply works be kept small. In all undertakings of a similar nature in the United States it is the practice to employ a number of small dynamos and engines, each forming one integral unit of the supply works, and to throw them into circuit as and when the supply demands. I have before advocated that each unit dynamo forming part of the installation should not exceed 10 per cent. of the total station capacity, as by this means, should an accident happen to one of the units of supply, no serious inconvenience would be felt until another could be thrown into circuit to take its place; and further, no more units of supply plant would be at work at any moment than the output might demand; thus always working the machinery, both electrical and mechanical, at its greatest efficiency.

Although in a town lighting supply there is a portion of the twenty-four hours in which the demand is very considerably above the average, it must not be forgotten that, even with gas works and all their storage plant, during such periods of great demand the supply is *not* up to the requirements, and that the pressure in the mains falls in consequence. This is perceptible in the jets, and may be easily noticed. I remember that Mr. Edison, when advocating the three-wire system, called attention to the habit of the average householder, who instinctively turns his gas taps either more or less on if he finds the pressure in the pipes too great or too little, and trusted to this same habit to compensate for excess of load on either circuit in the three-wire system by making the householder unconsciously regulate the supply when he began to "meddle" with the switches. It is quite possible to imagine a similar scheme of compensation when distributing by alternating currents and transformers; and after all, if the demand is greater than the output, the worst that can happen is that the lights are dimmer than they should be, and such an excessive demand is only for a very limited time.

In estimating for the ideal installation taken by Mr. Crompton, I will assume the conditions laid down by him in his estimates, and will treat only of the A.T. system, taking it for granted that the cost of a similar undertaking carried out by the B.T. method is accurately arrived at by him. For the sake of clearness, I will state the conditions upon which my estimate and the proposed undertaking is based.

1. The central station is to be 1760 yards from the exterior of the district to be lighted.
2. Within this district there will be fixed 15,000 lamps.
3. Of these 15,000 lamps the maximum number that will be in use at any given moment is 10,000.
4. Each glow lamp requires 100 volts and ·6 ampère or 60 watts delivered to its terminals.
5. The length of the distributing main will be such as to comprise 9000 yards of house frontage and 3000 yards of street crossings.
6. Both supply and distributing mains are to be laid underground.
7. The transformer stations may be placed in any convenient positions within the area of supply, and consequently the supply mains may be laid together with those for distributing the current within the area in the same conduit.

I estimate that a building to hold the necessary plant, consisting of boilers, engines, dynamos, &c., if erected at a cost of say sixpence per cubic foot, would, together with smoke stack, engine foundations, boiler settings, and all such items, cost about £6,500. In order to get 600 kilo.-watts delivered in the lamps, about 1200 brake horse power would be required, to which may be added 25 per cent. for loss in engines and transmission, &c.; this would give 1500 i.h.p., and to this amount I will add the same reserve power of 20 per cent., or a total effective power erected of 1800 i.h.p. This is a larger amount than either of the two former writers have allowed in their estimates; but I have based my estimate on the assumption derived from practice, that 500 watts can be delivered to the lamps for each brake horse power of the engines, and I would not be inclined to estimate for a lower amount. I fail to see how Mr. Crompton could have estimated that the buildings for the B.T. and A.T. systems would cost £8,000 and £11,000 respectively. He has perhaps allowed for the purchase of land, but I do not think that in an ideal estimate of this nature the question of the cost of the site should be included; but if included, it would be greatly infavour of the A.T. system. I also do not admit that a building to hold the A.T. plant would cost three-eighths more than a similar building for the B.T. machinery; if anything, the latter should cost more, as space would have to be acquired for the batteries within the area lighted, and certainly a very much larger room would be necessary to contain the cells than would be requisite for a transformer of equal power. This is evident. The generating plant I would propose to erect would consist of twelve engines and twelve dynamos, each indicating 150 h.p., also four exciters, two of which would be ample to serve the ten engines and dynamos required to produce the 600 kilo.-watts. Each alternating dynamo would have its own engine, and be driven by a strap, or coupled direct to the engine, but no counter shafting could be allowed. The dynamos would all be connected to a main switch board, so that each or all the machines, if necessary, can be thrown in parallel into the supply mains as the outside demand requires. No more dynamos would be at work at any moment than the supply necessitated, so that each *unit* of the plant would work at its greatest efficiency.

The supply mains would be laid underground from the engine house to the area of supply, and I have considered that they would also have to be laid for half the length of what Mr. Crompton calls "useful frontage" within the area, say 600 yards. This would give a total distance of say 2400 yards, or, there and back, 4800 yards. The cost of such a cable to carry 300 ampères at 2000 volts I estimate at about £4,300. I have only allowed for 600 yards inside the area, because, although the supply mains would be laid almost throughout the district to be lighted, the size within the area will necessarily become less and less as the current required to supply each transformer is taken off, so that the furthest transformer will be fed by a current of perhaps less than one-thirtieth part of that amount required to be conveyed by the supply mains up to the area of supply. The amount I have therefore allowed, of *half* the length of mains at *full* size, is ample. As regards transformers and distributing mains within the 1200 yards of useful frontage, I would propose to fit one hundred transformers, of an average output of 6 kilo.-watts each. These would then be placed at about 12 yards apart, and consequently the current they would each have to give out in the secondaries would only be 60 ampères. Two thousand four hundred yards of distributing mains to carry this current to 12 yards on either side of a transformer would only cost say £250, as the potential being not more than 100 volts, a lower class of insulation could be allowed. One hundred transformers of about 9 h.p. each would certainly not cost more than £2,700, and if we allow £2 per h.p. for fixing, switches, &c., a further £1,800 must be added.

For the necessary laying of the conductors, opening up streets, providing conduits, &c., I allow 10s. per yard, or say £1,500 for the 2960 yards of roadway opened; 1760 yards without, and 1200 yards within the area of supply. This is as far as we have to go, for service mains, house connections, and wiring do not form part of our estimate, which may therefore be summarised as follows:—

Buildings, foundations, &c.	£6,500
Boilers, fourteen to indicate 120 h.p. each	5,320
Engines, twelve to indicate 150 h.p. each	7,200
Dynamos and exciters	7,000
Supply mains, 4800 yards	4,300
Distributing mains, 2400 yards	250
Laying mains in conduit	1,500
Transformers, 900 e.h.p.	2,700
Fixing ditto	1,800
Station fittings, &c.	500
	£37,070

Say £37,000, or £3. 14s. per lamp.

Mr. Crompton allows nothing, I observe, for contingencies, and generally in an estimate 10 per cent. ought to be allowed on this account; but I have not done so, in order to make the comparison fair. This, then, may be taken as the probable cost of an undertaking based on alternating currents and transformers; and if such a work were to be carried out, we should have a plant capable of easily running the lights required, with 20 per cent. reserve power, always worked at the greatest efficiency; entailing no large loss from depreciation and wear and tear, with perfect control over the supply, as well as simplicity and economy combined. Can Mr. Crompton allege the same for wasteful batteries, always requiring attention and repairs; for sparking dynamos, expensive regulating gear, heavy mains entailing general and continual anxiety?

As regards annual cost of maintenance and working expenses, I do not believe the two will bear comparison, and I should be glad to compare notes with Mr. Crompton in this respect, if he would calculate the probable yearly expenditure upon a similar installation on the B.T. system.

Yours, &c.,

J. Kenneth D. Mackenzie.

Westminster, 9th April, 1888.

FORCED DRAUGHT.

To the Editor of "Industries."

Sir,—Referring to the article on this subject in your last week's issue, I was somewhat astonished to find that the question of forced draught for boiler furnaces has not been much further developed. Some years ago—I think more than twenty—Dr. Percy, in a lecture given before the Society of Arts, showed that, at a pressure above that of the atmosphere, the contact of the atoms of oxygen in the atmosphere with those of the carbon and hydrogen was so much closer than under a minus pressure caused by heated air ascending in a chimney, and that more of the oxygen became effective and less passed up the chimney in a free state. Not only that, but more of the carbon was completely burnt, forming CO^2, instead of simply CO. That being the case, less atmospheric air is required for the complete combustion of the coal; and, therefore, less useless nitrogen passes through the fire to become heated, and in that way carrying a large portion of the total heat away into the atmosphere. So much for the economy of the thing. The practice has been carried out for a number of years by Sir Henry Edwards at his mills at Sowerby Bridge, and I never

Digitized by Google

heard of any had effects produced upon the plates in the fire boxes of the boilers. Certainly, your last week's issue, or at least the portion of it referring to this matter, looks to me like some old periodical of twenty years ago.

Yours, &c.,

Bolton, 7th April, 1888. ALPHA.

AMENDMENT OF THE PATENT LAW.

To the Editor of "Industries."

SIR,—I have read with much interest your notice of the amendments in the patent law which the Institute of Patent Agents seek to promote. There are so many erroneous ideas afloat as to the nature of a patent agent's business and of his duties, that I beg leave to say a few words about the necessity for limiting practice in this profession to those who are able to show that they are qualified for it. At the present time any person may act as a patent agent, take fees, and profess to give that assistance which the inventor seeks. That is to say, anyone, however incompetent and however ignorant, may pretend that he can and will draw up a specification which will "hold water" in the Courts.

I know that a good many well intentioned people imagine that the inventor himself should be best qualified to do this. It is, however, undeniable that, to make a clear, comprehensive description of anything requires a talent which is quite beyond the gifts of many an ingenious constructor. To grasp, and in a few crisp words to set down what is the precise point of novelty in an invention, requires a highly trained analytical capacity, which also is rare amongst inventors, who are too prone to mistake the advantages presented by their improvements for the means by which they are obtained, the latter being capable of protection, whereas the former are not, when considered independently of the means. Add to this that, in order to make a satisfactory specification, precedents as established by the Courts should be kept in view, and it will be obvious that a patent agent who is to be a real help to his client must be as highly trained in his profession as lawyers, physicians, and others are in theirs. This is all the more necessary as the inventor wants help, not only in obtaining a patent in England, but in other countries also, and each country has laws of its own which have to be studied. That many who now practice are in every way unsuited for the work they undertake none know better than the qualified patent agents who are brought into contact with the work of the "black sheep" when, as a rule, the mischief is beyond repair.

Lest some of your readers imagine that the possibility of amendment granted by the Patent Acts is sufficient to save the inventor from harm, I may point out that an amendment may not enlarge a scanty claim, but only reduce an excessive one, and that, if the invention prove valuable and successful, the amendment is opposed almost as a matter of course by some one who is interested in the matter, and who generally is allowed to go scot-free for past infringements. Briefly, if a specification is badly drawn, an injury which is beyond repair is inflicted upon the patentee, and therefore means are required to prevent such damage being worked by unqualified men. The authorisation to practise should, I think, come from the Patent Office as represented by the Comptroller, and in case of refusal an appeal should be allowed to the law officers. I mention an appeal not because I have any fear that the Comptroller would intentionally withhold his certificate from anyone who has a fair claim to it, but because I think that those to whom he would most properly refuse it should not have even the semblance of just complaint left to them. It is but natural that the license should be revocable for misconduct, for incompetency, and for breach of trust. I do not think that a single patent agent of any standing would feel aggrieved by such a system, and I am sure that inventors would benefit considerably if a roll were established. It might be well to have a small annual fee for the license, but this should not be so heavy as to deter poor men from practice.

Yours, &c.,

London, 4th April, 1888. BERNARD DUKES.

THE DEFENCE OF OUR MERCANTILE PORTS.

To the Editor of "Industries."

SIR,—I think your article of the 30th ult. is a useful one as tending to direct the mind of the public in the right direction. I believe that in the report of Mr. Stanhope's Committee, a clerical error has perpetuated a grave mistake. It is said there, that the attack to be expected on our mercantile ports will be made by "armoured" cruisers; I understand that the term should be "armed," not "armoured," cruisers. Naval experts would not have been likely to use the other term, and I believe the guns it is intended to mount for the defence of the ports will not, as a rule, be armour piercing. It is not easy for a naval man conversant with the facts of naval history, remote and proximate, to share in the great alarms now in circulation with reference to the safety of the commercial ports, if reasonable steps are taken in the direction you mention towards keeping the navy paramount. If, after the navy is certainly made paramount at sea, our citizens feel alarm for particular parts of our coast and can spare the money, there is no reason why they should not make assurance doubly sure. But the danger we are in at present arises from our growing conception that fortresses and submarine mines are a substitute for the command of the sea, and for naval defence. There is no ground for such a belief, either in history or in reason. We must never forget that in any serious naval war our naval operations will be hampered with the weight of our commerce, whereas the first thing any possible opponent we could have would do, would be to lighten himself by getting rid of the whole of his sea-borne commerce. In our first war with Holland, the Dutch tried to carry on the war and their commerce together. In the second and third they began by forbidding their merchant ships to leave their harbours. Germany, in our own time, did the same thing in her war with France. She closed the whole of her ports, and telegraphed all over the world for her merchant ships to remain in their neutral harbours till the war was over. France, on the other hand, was able to assert her command of the sea, which was very nearly a complete protection to her commerce everywhere, and by consequence an absolute protection to her coasts and ports. But France, though in this absolute state of power at sea, with an ironclad squadron off the German ports in the North Sea, and another off the German ports in the Baltic, deliberately considered, and deliberately rejected, all proposals for sudden extemporised attacks on German ports which were at all thrust inland. A decision was come to to bombard a small coast town—Colberg—which could as easily be got at from the sea as Sunderland or Hartlepool; but this, owing to circumstances, did not come off, though it was the sole attack considered feasible. At the same time it was clearly decided that Kiel, Hamburg, or any port could, and would, were the war prolonged, be made the object of deliberate organised attack with proper appliances and plenty of time. These decisions were in accordance with the whole course of naval history. Mere sudden passing attacks—*coups de main*—were never uncommon, but were confined to places exposed to the open sea—those most easily got at. Serious conquering attacks, from the time of the Dutch raids up the Medway and the Thames, to Farragut's wonderful capture of Mobile, were directed up inlets and estuaries, but only when the command of the sea was complete behind the attacking force. I do not know that any of those who believe in the danger to the commercial ports, which we are now spending heavily to repel, are thinking of the conditions under which Farragut attacked Mobile, or Bouet-Willaumez declined to attack Kiel. They do not postulate the loss of the command of the sea by England, they only postulate an attack hasty in conception, carried out in a hurry, and more or less in fear of the arrival of an equal or superior English naval force before the work is done. But I think their hypothesis must throw over every lesson of history, experience, or reasonable probability. I know of no train of reasoning, no array of facts, or of reasonable suppositions, which will permit me to agree with them. But, on the other hand, if they postulate the loss of the command of the sea to England, navally armed as she is at present or is likely to be for some time—unless she wakes up—then, though I am neither alarmist nor pessimist, I cannot say they are unreasonable. The first steps in asserting the command of the sea—whenever we have had it—has always been to mask our enemy's main fleets in their own ports, and either to prevent them coming out, or to fight them and render them too far neutral should they come out. This can only be done by placing at least an equal force to what they have inside of armour clads in the immediate vicinity of each of the enemy's ports. Taking France, there is a reasonable belief that she would now muster fifteen ironclads at Toulon, five at Brest, and nine at Cherbourg. It is not usual to say this, because two of the ships at Brest and four of the ships at Cherbourg are coast defence vessels. But they are all powerful armour clads, quite competent to fight an armour clad in their own waters, though not prepared to go far to sea. If we sent three armour clads off Brest, it would be unreasonable to suppose that they would not be beaten by the three armour clads and the two coast defence armour clads there, which could come out and fight them. If we sent only five armour clads off Cherbourg, we could hardly hope that they would not be forced to retire before the five and the four which would there come out to fight them. No one has ventured to credit us with more than thirty ironclads, and it is evident that under such conditions we should be at the bare end of our armour clad resources. But it is worse than that, for the French forces inside the harbours would remain intact and ready—for months if necessary. It would be impossible with only nine armour clads to keep nine armour clads at sea off Cherbourg, or with five to keep five at sea off Brest. Coal and foul bottoms—the latter as great a trouble as it was two hundred years ago—would necessitate constant relays, and we have them not. I suppose that to keep five ships off Brest, the very least reserve necessary would be two, and to keep nine ships of Cherbourg, a reserve of three would be necessary. There are no such reserves.

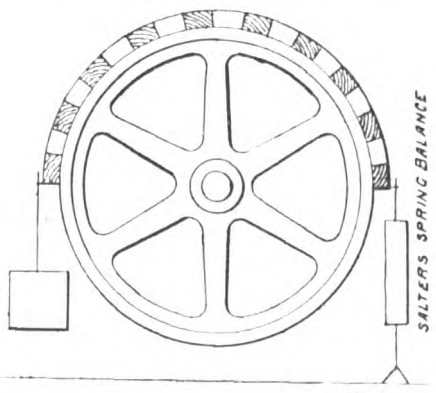
I saw it stated in an influential paper the other day that it did not matter about armour clads as long as we could protect our commerce. A curious error to fall into if one imagines how commerce is to be protected when nine enemy's armour clads are placed between the Isle of Wight and Cape La Hague. In these waters there is a British ship wanting to come either way every ten minutes or so, and one does not quite see how they are to gratify their desires under the circumstances. It is about two hundred years since an enemy's fleet has occupied that advantageous position; but when it did, it took excellent care of our commerce according to its lights. This is one side of the picture, the other is this: that this same superior squadron, in the Channel now, must confine itself to the commercial business because of that squadron of ours which has retired before it. It was precisely the case of the great French fleet two hundred years ago, and it would be so now. It would be a superior fleet only while it held a superior position in the vicinity of Cherbourg. If it went away after a commercial port—even if it took the whole of the ships, which it could not, as four of them could not quit their base—yet could they not dare to set about an attack on a commercial port for fear of the inferior squadron catching them at a disadvantage in the middle of the business.

We are always told now, in preparing to spend a million or two on some kind of defence which is not naval, that we are to begin by assuming that we have no Channel Fleet. Though it is, or ought to be, rather a startling assumption, our forefathers at the beginning of this century, when war had taught them the lessons we are so complacently forgetting, would have but said: "What then? There is our reserve in the Downs," and they would and did decline to spend money in the face of that fact. So now with us, we cannot, perhaps, have a reserve fleet after we have masked the French in Toulon, Brest, and Cherbourg, if we spend the money which would have gone on that reserved fleet in forms of defence which are not naval. But it seems impossible to doubt, if we add up all the millions that have gone, that are going, and that are to go, in defending each port in England separately, that for a great deal less money we could have our old reserve fleet in the Downs, in war, connected with every port by electric telegraph and—merely by its attitude—preventing hostile squadrons, which could only get to sea by the failure of our masking squadrons, even dreaming of such a thing as an attack upon them. So, if I am asked to consider the mysterious disappearance of what people, not understanding fully, are pleased to call the Channel Squadron, I answer at once, give me my Downs Reserve, and I should decline to answer any more questions till I had got it. For it is plain to be seen that this Downs Reserve would not only protect the commercial ports, but would keep the command of the sea, and make the first step towards commerce protection, which no fixed defences can make.

Yours, &c.,

London, 7th April, 1888. P. H. COLOMB.

REPORT ON THE "GRIFFIN" PATENT GAS ENGINE.



THE following report on the "Griffin" patent double acting horizontal gas engine, by Professor Jamieson, professor of engineering at the Glasgow and West of Scotland Technical College, will no doubt be read with interest. An illustration of this engine is given on page 374.

[COPY OF REPORT.]

To Messrs. DICK, KERR, & Co.,
101, LEADENHALL STREET, LONDON, E.C.

GENTLEMEN,—I have now the pleasure of reporting to you on the results of my examination and tests of your 8 h.p. nominal "Griffin" patent gas engine, as made at your Britannia Engineering Works, Kilmarnock. My tests extended over four hours on November 25th, four hours on November 26th, 1887, and over one hour on January 27th, 1888.

The engine, in its general style and behaviour, more closely resembles that of an ordinary double acting steam engine than any other gas engine with which I am acquainted, for both ends of the cylinder are closed in, and an impulse is given to the piston every one and a half revolutions, *i.e.*, combustion takes place at each end of the cylinder alternately every three revolutions of the crank shaft, when the engine is working under normal conditions. This feature naturally causes the *speed of the gas engine to be more constant than single acting gas engines, and therefore better adapted for driving dynamos* or other machinery where constant speed is required. The governing and ignition of the combustible mixture (gas and air) are effected in a manner similar to most gas engines—the former by entirely cutting off the gas supply, and the latter by plain slides. The charging and exhaust valves are of the lifting type. They are actuated by a simple and neat arrangement of cams on a side shaft, which is driven by worm gear from the crank shaft. The engine has been specially well designed with the view of transmitting the working stresses to the foundation, and thus avoiding as far as possible any annoyance from vibrations and racking. Great care has been taken to make all the working parts strong and simple, while the workmanship and finish throughout seem to me all that could be desired. Throughout the whole of my electrical test the *engine* WORKED VERY STEADILY; *in fact I have never before tested a gas engine which maintained such uniformity of speed* at full power, *no pulsation or blinking being observable in the incandescent lamps.* The mechanical efficiency or ratio of brake horse power to indicated horse power, as shown by the following results, is equal to 78·7 per cent., thus proving that but a comparatively small proportion of the whole power developed is absorbed in working the engine itself. The engine is very powerful for the so-called "nominal" horse power (a term still common among gas engine makers); in fact, it develops very nearly double the nominal horse power on the "brake." The absolute and the practical efficiencies or ratios of indicated horse power and of brake horse power to gas consumption in terms of heat units (as demonstrated in the appendix), are respectively equal to 19·2 per cent. and 15·1 per cent.; *which results are better than I have obtained from any other gas engine.*

Industries.

The following tests were mainly directed to two objects, viz.: (1) To obtain simultaneously the indicated and the brake horse power; (2) to obtain simultaneously the indicated and the electrical horse power. The following instruments were used by me in obtaining data for my results, viz.; (1) A Richards' indicator of Elliot Brothers' make, with spring yielding $\frac{1}{64}$in. per lb. of pressure per square inch, was used for taking the pressure diagrams from each end of cylinder at intervals of about five minutes during the various tests for the indicated horse power. (2) A revolution counter of Schaffer & Budenberg's make was fixed direct to the slide valve shaft, whereby the exact number of revolutions were obtained. (3) A Young's tachometer of Elliot Brothers' make was connected to the crank shaft, and another to the dynamo spindle, as a check on the mean revolutions per minute, and to indicate variations of speed. (4) A gas meter (Alder & Mackay's), 80-light, sealed and certified correct by an Edinburgh gas company's official, was used to measure the gas supply for developing the power. A separate small meter was used for the pilot and ignition lights. (5) Two thermometers (Fah. scale) were employed to indicate the rise in temperature of water passed through the cylinder jacket, one being placed on the supply tank, and the other where the water left the cylinder jacket. (6) A water supply tank,

fixed a short distance from and a few feet above the cylinder of the engine, with a regulating cock close to the same, was used to give any desired flow of water through the cylinder jacket. The quantity of water passed through the cylinder jacket was reckoned by careful measurements of the fall of water in the tank every five minutes. (7) The brake used was of the form shown on the preceding page, and one was placed on each fly wheel. It consists merely of a strap and blocks, with the dead weight on the one side, and a spring balance attached to the floor on the other. The load on each wheel, as well as the several dimentions, were as nearly as possible the same. The mean reading of the spring balance, plus part of the weight of the spring balance, was deducted from the dead weight, to arrive at the *net brake load* on each wheel.

Brake Tests.

Duration of test in minutes	60
Total revolutions in sixty minutes	11,016
Mean revolutions per minute (n)	183·6
Mean effective radius of brake load, in feet (r)	2·78
Mean net load or brake, in lbs. (p)	140
Brake horse power from above $\left(\frac{2\pi r n p}{33{,}000}\right)$	13·6
Number of indicator cards taken	12
Mean effective pressure from twelve cards, in lbs.	64
Indicated horse power from above	17·28
Gas used by engine in sixty minutes, in cubic feet.	333
Gas consumption per brake horse power	24·48
" " *indicated horse power*	19·27
Percentage efficiency of engine $\frac{\text{brake h.p.}}{\text{indicated h.p.}} \times 100$	78·7

The following instruments and appliances, in addition to those previously mentioned, were used, viz.:—(1) Dynamo: One of the fly wheels was connected direct by belt to a Rankin-Kennedy single magnet horseshoe compound wound dynamo of about 8000 watt power, which was kept running steadily at about eight hundred revolutions per minute. (2) Lamps: In parallel circuit with the dynamo were placed eight large incandescent lamps, capable of giving five hundred candles each, with twelve ampères at 80 volts, and one sixteen candle lamp. (3) Voltmeter: The difference of potential between the terminals was measured by a Cardew voltmeter. (4) Current Meter: The total current passing through all the lamps was measured by a Siemens electro-dynamometer. The voltmeter and ampère meter had been tested before leaving the Woodside Electric Works, and simultaneous readings were taken on each every five minutes.

Tests when Driving Dynamo.

Duration of two tests combined, in minutes...	45
Revolutions of engine fly wheel, per minute...	187·7
Mean pressure in cylinder, in lbs. per sq. inch.	63·2
Indicated horse power (from above data)	17·4
E.M.F. at lamp terminals, in volts	79
Current through all the lamps, in ampères ...	92
Electrical horse power spent on all the lamps.	9·74
Ratio of electrical to i.h.p., per cent.	55·8
" " brake h.p., per cent.	71
Gas used in cubic feet, per hour (without including pilots)	333
Gas used in cubic feet, per minute $\left(\frac{333}{60}\right)$	5·55
Heat equivalent of the 5·55 cub. ft. of gas used per minute in foot-pounds ($5{\cdot}55\times691\times773$) =	2,964,500
Water passed through cylinder jacket, in lbs. per hour	1,272·4
Mean rise in temperature of the above water in degrees Fah.	55°
Heat carried away by water per minute in B.T.U. $\left(\frac{1272\times55}{60}\right)$ =	1,166
Heat equivalent in foot-pounds ($1166{\cdot}4\times773$) =	901,600
Percentage of total heat carried away by jacket water $\left(\frac{901{,}600}{2{,}964{,}500}\right)\times100$ =	30·4

It remains, therefore, only to estimate the heat passing away in the exhaust and scavenger strokes and by radiation, which is done here "by difference," so that we have of the total heat due to the combustion of the gas:—

	Per cent.
I. *Converted into indicated horse power*	19·2
II. *Carried away by the cooling water*	30·4
III. *Discharged in exhaust and scavenger strokes, and by radiation, &c.*	50·4
	100·0

APPENDIX I.

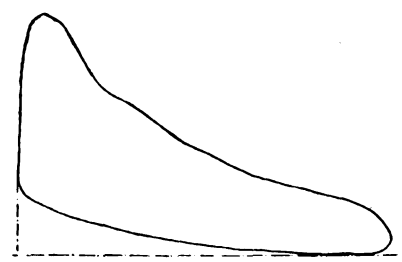
Determination of the heat evolved per cubic foot of gas used during the tests.

A sample of the gas was analysed by Mr. C. J. Wilson, F.I.C., F.C.S., and gave the following results:—

Carbonic acid and oxygen gas	·5
Carbonic oxide, CO	4·1
Olefines, C_2H_4 and C_4H_8	5·5
Marsh gas, CH_4	43·4
Hydrogen, H	44·1
Nitrogen (by difference)	2·4
	100·0

The percentage of C_2H_4 and C_4H_8 should have been given separately, because the heat value of C_2H_4 is only about half that of C_4H_8 for a given volume. Assuming, however, that two-thirds of the olefines is C_2H_4, and one-third is C_4H_8 (which is probably not far from correct), we get the results shown in Table I.

Table I. shows the amount of heat evolved by the complete combustion of 1 cub. ft. of the gas measured at 14·7lb. pressure, and 32°F., but the pressure was 14·8lb. per square inch, and the temperature 67°F., hence the heat evolved per cubic foot of the gas used will be



$$= 745{\cdot}7 \times \frac{14{\cdot}7}{14{\cdot}8}\left(\frac{460+32}{460+67}\right) = 691 \text{ B.T.U.}$$

Taking one B.T.U. as equivalent to 773 foot-pounds, the heat evolved by the complete combustion of 1 cub. ft. of the gas is equivalent to 691 B.T.U. × 773 = 534,500 foot-pounds.

Heat evolved by complete combustion of 1 cub. ft. gas		534,500
Gas used in cubic feet per brake horse power per hour	=	24·48
Do. equivalent in foot-pounds ($534{,}500\times24{\cdot}48$)	=	13,085,000
1 h.p. in foot-pounds per hour ($33{,}000\times60$)	=	1,980,000
Practical efficiency of engine $\left(\frac{1{,}980{,}000}{13{,}085{,}000}\right)\times100$	=	15·1 per cent.
Gas used in cubic feet per indicated horse power per hour	=	19·27
Do. equivalent in foot-pounds ($534{,}500\times19{\cdot}27$)	=	10,300,000
Absolute efficiency of engine $\left(\frac{1{,}980{,}000}{11{,}108{,}172}\right)\times100$ =		19·21

APPENDIX II.

Determination of equations for compression and expansion curves from the indicator diagram attached (which is a sample of a large number taken from both ends of the cylinder).

Let V=volume in cubic inches occupied by the gas at any part of stroke.

Let v=volume in cubic inches through which piston has swept from end of stroke.

$\therefore$ V=v+404 (where 404 cub. in. is the volume of clearance space at back end of cylinder).

Total volume swept by piston=890 cub. in.

P=absolute pressure on expansion curve.

p=absolute pressure on compression curve.

[See Table II.]

The equation to the curves will be $PV^m=k$ (a constant), and $pV^n=k^1$ (another constant).

Hence we have log P+m log V=log k; and log p+n log V=log k^1.

$\therefore$ If log P and log V are taken as co-ordinates of points and plotted on squared paper, these points ought to lie in a straight line. From a square paper diagram it is evident they lie very nearly in a straight line. Taking the straight line which lies most evenly among them we have:—

Log V=3·07 where log P=1·73
and log V=2·73 where log P=2·2

$\therefore$ $1{\cdot}73+3{\cdot}07m=\log k$
$2{\cdot}2+2{\cdot}73m=\log k$
$\therefore$ $m=1{\cdot}382$, and $k=926{,}000$

Hence the equation of expansion becomes $PV^{1\cdot382}=926{,}000$.

In the same way the equation for the compression curve is found to be $pV^{1\cdot4}=263{,}000$.

For an isothermal curve the formula is PV=k, and for an adiabatic curve the formula is $PV^{1\cdot375}=k$.

From the above, the expansion curve is evidently but very slightly steeper than an adiabatic curve, thus observing that the rate at which heat is generated during expansion, is nearly the same as the rate at which it is carried away by the water in the jacket.

The compression curve is also seen to be rather steeper than an adiabatic curve, thus showing that the mixture gains heat from the piston and the end of the cylinder, which more than compensates for the loss to the water jacket during compression

THE TIMMIS SYSTEM OF TRAIN LIGHTING BY ELECTRICITY.

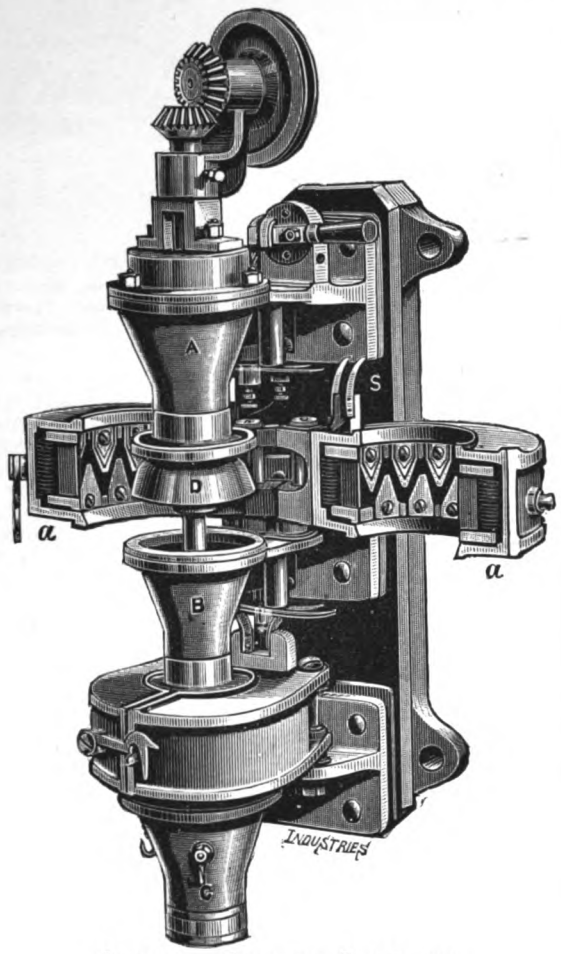
ALTHOUGH on the first glance the problem of lighting railway carriages by incandescent lamps seems a simple one, careful consideration shows that it is coupled with many difficulties, which arise chiefly from the necessity of so arranging the lights that they should be independent of each other, no matter how the train is made up. Various methods have from time to time been brought forward, and among those which were most successful, or, to speak more correctly, the failure of which was the least conspicuous, we may mention the following: (1) The direct system of lighting by means of a dynamo driven by a separate engine, and supplying current to mains which run the whole length of the train, and to which the lamps are connected. A very early example of this system, and perhaps the first example in England, was the installation tried by Mr. Massey several years ago on a London suburban train. In this case the dynamo and engine were placed in the front guard's van, and the lighting was under the control of the guard. Another example is the experiment made by the Great Eastern Railway, some four years ago, when several locomotives were fitted with steam dynamos (Crompton machines and Tower engines), and a cable, with special couplings, was laid throughout the train, from the locomotive to the last carriage, branches being taken off to the glow lamps, which were all coupled in parallel. The great objection to either system is that all the carriages in the train must be provided with electric fittings, for if a carriage not so fitted be inserted, all the carriages behind it would be cut off from the supply of current. Another objection is, that if the train has to be split up at a junction, and one portion be coupled to a train not provided with the same electric light apparatus, this portion will not be lighted at all, since the usual oil lamps have been replaced by incandescent lamps. The system appears therefore only applicable to short suburban trains, the make-up of which is never altered. The system is also objectionable because of imposing upon the engine driver or guard the additional duty of attending to the steam dynamo. This duty becomes particularly irksome on lines containing many tunnels, because, in the daytime, the dynamo must be started and stopped each time the train passes a tunnel. (2) The combined dynamo and battery system of electric train lighting, which is in use on a number of trains of the Brighton Company, and which has also found considerable favour on the Continent. The arrangements vary according to local circumstances; but the essential features are a dynamo and a set of accumulators, the dynamo being placed in the guard's van, and driven by belt gear from one of the axles. Automatic appliances are necessary to keep the electromotive force of the dynamo within such limits as will insure the batteries not being damaged by an excessive charging current on the one hand, and will, on the other hand, prevent a back discharge from the battery through the dynamo. For the latter purpose an arrangement must be provided which interrupts the charging circuit when the speed of the train, and therefore that of the dynamo, has fallen below a certain limit. All these automatic appliances are objectionable, because of their liability to get out of order The dynamo and gearing take up a large amount of space in the guard's van, which is of great value in main line trains; and the belt gearing, which is necessarily more or less exposed to dust on the road, entails a heavy outlay for maintenance. The depreciation of the dynamo and engine is also great, because guards' vans are often left standing in a siding, and the machinery is therefore liable to be neglected. Another objection is, that whilst the

Digitized by Google

THE TIMMIS SYSTEM OF TRAIN LIGHTING BY ELECTRICITY.

batteries cannot be charged when the train is standing, the gear must always be worked when the train is in motion, whether the light be required or not. (3) The system of sub-divided batteries with or without dynamo carried on the train. The essential feature of this system lies in the employment of small storage batteries, one being fitted to each carriage. It is evident that by this means the lighting of each carriage is rendered perfectly independent of the other carriages, and also independent of the way in which the train is made up; but as hitherto carried out, the control of the lights in each carriage during the day when the train is going through tunnels, could not be effected from one place in the train by the guard, as in the previous systems. The lamps must therefore either be under the control of the passengers, or an attendant must be provided for every carriage. This system has since the beginning of the year been in use on the Alsatian State Railways, where the battery of each carriage consists of thirty-six cells carried in a tray, for facility of handling at the charging station. The batteries, which are of 40 ampère hours capacity, are fitted in the place of the gas reservoirs underneath the carriages, and are charged at certain stations which already possess electric lighting plant. Each carriage is fitted with five 10 c.p. lamps, requiring together about 3 ampères of current, so that the batteries have sufficient storage to light the train for thirteen hours before being re-charged.

A similar system of electric train lighting has been introduced into this country by Mr. J. A. Timmis, of 2, Great George-street, Westminster; but it is a great improvement upon the system in use on the Alsatian lines, and has been worked out quite independently. Mr. Timmis employs sub-divided storage batteries, ten of the Union Company's cells being placed under each of the carriages composing the train; but the lighting and extinguishing of the lamps is performed by the guard and not left to the passengers, thus removing the objection we have above alluded to. There are, however, other advantages connected with this system which we shall presently describe. Experiments with the Timmis system were begun on the Midland Railway in October last, and an electrically lighted train is now regularly running between Derby and Manchester. The light is supplied to a saloon carriage, a composite first and second class carriage, and the guard's van. Each battery, as already stated, consists of ten of the Union Company's storage cells, and weighs about 4cwt. These batteries are charged by a dynamo at the station at Derby, and supply current to 5 c.p. Swan lamps, of which two are placed in each compartment of the ordinary carriages, and four in the saloon. In this system, Mr. Timmis does not only provide for the electric lighting of every carriage independently of the others, but he also utilises the electric apparatus as a means of inter-communication between passengers, guard, and driver, and to a certain extent as an automatic alarm which will give notice in case the train parts. It is not necessary that the storage cells should be charged at the station, and Mr. Timmis has elaborated an arrangement by which the train is rendered perfectly independent of a fixed charging station, each locomotive being provided with a steam dynamo, which is used for charging all the batteries in the train from mains running from the locomotive to the last carriage. In elaborating his plans, he laid down the following conditions as essential to meet the requirements of railway engineers in lighting trains electrically: (1) Every vehicle must carry its own lighting power, because it may be put into a siding, or be slipped or break loose from the train; (2) the guard of the train must have the power to light or put out all the lamps in the train without quitting his van; (3) if a portion of the train is slipped or breaks loose, the lamps in that portion, as well as in the front part of the train, if lit, must remain lighted, and if they are not lit they must automatically light up so as to give the passengers warning that an accident has happened. This last condition is important, because it may happen that a train parts after leaving a tunnel, and while ascending an incline, when the rear vehicles will run back into the tunnel. If such an accident happens in the day time, the lamps in the whole of the train will automatically light up, and thus give notice that the train has parted. By the courtesy of Mr. Timmis we are enabled to put before our readers a diagram showing the manner in which these various functions are performed by the electrical apparatus.

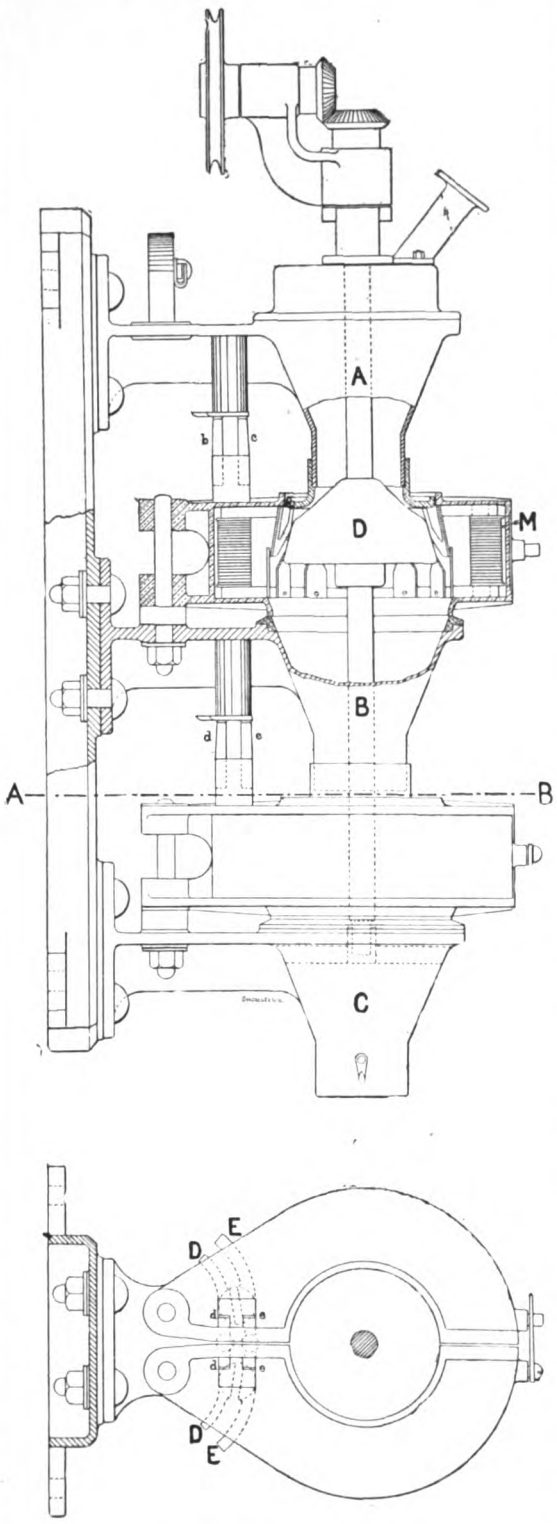


The steam dynamo is placed on the tender, as shown in the sketch of a portion of a railway train on the top of the diagram, and a four conductor cable with suitable couplings is led from the dynamo to the guard's van, and from there to the successive vehicles. Each vehicle is provided with a small local battery, marked Acc: in our illustration, weighing from 180lb. to 250lb., according to the size of the vehicle and the number of lamps in it. There is also in each carriage a local lighting circuit with the lamps in parallel, a magnetic switch M, and a communication pull P. The guard's van contains in addition a call bell B and a controlling switch C, the function of which will be presently described. Another call bell is placed on the locomotive. The dynamo D is driven direct by a high speed engine E, and the current from it is controlled by a magnetic switch O. In our illustration the four conductors of the main cable are shown by the lines A B C D. Circuit A leads from the negative terminal of the dynamo through the switch O to the end of the train, and branches are connected in each vehicle to the batteries, call bells, and negative local lighting circuit, the latter branches passing through the magnets M S. In the guard's van this magnet is omitted and the connection is direct. The circuit D is similarly connected with the positive terminal of the dynamo, the positive pole of the local batteries, and with the positive branch of the local lighting circuit. The two middle circuits B and C serve respectively for the pull communication and call bell, and for the magnetic switches M S. Each vehicle has a local lighting switch L, which is opened when the carriage is not in use in order that the current may not be wasted; but this switch is always closed when the carriage is in service, whether the light be required or not. The control of the current when the carriage is in service is not effected by the switch L, but by the magnetic switch M S. When the magnet M is energised, its core is pulled down and the switch S is thereby opened. All the magnets are controlled by the switch C in the guard's van. As long as this switch remains closed, a very small current flows through the magnets M and keeps all the switches S open, so that none of the lamps are lighted; but if the guard wishes to light up the train he opens the controlling switch C, the magnet M in each vehicle becomes demagnetised, a spring pushes the core up, and brings a contact piece into electrical connection with the springs of the switch S, thereby establishing a local circuit between the battery and lamps, and the latter light up. It will thus be seen that the lighting up is due to the breaking and not to the establishing of a current, and therefore, if the train should part, the current through the magnets M will be similarly broken, and the lamps will light up, giving the passengers notice that some of the carriages have broken loose. The bell circuit B is put into electrical communication with the general negative upon pulling out the plug P, when the springs which were previously separated by this insulating plug come in contact, and a current flows from the circuit D through the communication plug to the bell circuit B, thence through the bell and back to the accumulators or dynamo by the negative general circuit A. The connection of the four conductor cable between adjacent vehicles is effected by special coupling pieces, which we show in detail, and the arrangement of which explains itself. When no call bell is required, only three circuits and smaller couplings, with three contacts, are employed. The contact pieces are so arranged that it is impossible to couple the cables in any other way but that which is correct. It will be seen from the brief description we have here given of this system, that it complies with the requirements laid down by the inventor for a perfect system of train lighting without introducing any special complications. Mr. Timmis estimates that it will be possible to obtain an electrical horse power hour with an expenditure of from 40lb. to 45lb. of steam per hour, and in this case the extra amount of coal consumed by the locomotive for supplying current to a train fitted with 122 lamps would only be $\frac{1}{2}$lb. per mile. This estimate is based on the assumption that the light is required for a quarter of the time the train is in use.

THE HOLROYD SMITH MAGNETIC SEPARATOR.

The number of magnetic separators now in the market is considerable, but any apparatus of this kind hitherto constructed was intended for the treatment of a material in which the magnetic particles were of a size large enough for picking out by hand if required. Separators have become a necessity in many industries. As an example we might mention those which came into use shortly after the introduction of sheaf binders. As will be remembered, in the earliest combined reapers and binders the sheaves were bound with wire, and it often happened that when this wire was cut previous to the sheaf being introduced into the thrashing machine, a small piece of the wire, or perhaps the whole of it, passed through the drum, with the result that the finished grain as it was delivered from the machine contained occasionally short pieces of wire, and before the grain could be put on the mill these pieces of iron had to be taken out. This was done by magnetic separators of various designs; but since the abandonment of wire, and the introduction of string binders, magnetic separators are no longer required for treating grain. They are, however, largely in use for other purposes, notably for treating shop sweepings for the recovery of brass, copper, and gun metal. The particles of iron in this case, as in the previous example, are of fairly large size, and can therefore be acted upon

Digitized by Google



by a magnet at a considerable distance. The attraction of a magnet upon a particle of iron is a differential force. As the particle of iron comes into the field of the magnet, that end of it which is nearest assumes the opposite polarity to that of the magnet pole, and is attracted, whilst the opposite end, which assumes the same polarity, is repelled. The force with which the particle is drawn through the surrounding mass of non-magnetic material is equal to the difference between these attractive and repelling forces, and this difference will be the greater the greater the dimensions of the particle, not only because of the greater bulk of iron coming under the action of the magnet, but also on account of there being a more sensible difference in the distance of the induced poles from the inducing pole. It is thus a comparatively easy matter to separate magnetic particles from a loose mass of non-magnetic material if the particles are of fairly large size, such as chippings and turnings, or pieces of wire; but if the magnetic particles are in the form of powder, fine filings, &c., the problem becomes extremely difficult. It has, however, been solved in the magnetic

General View of Separator.

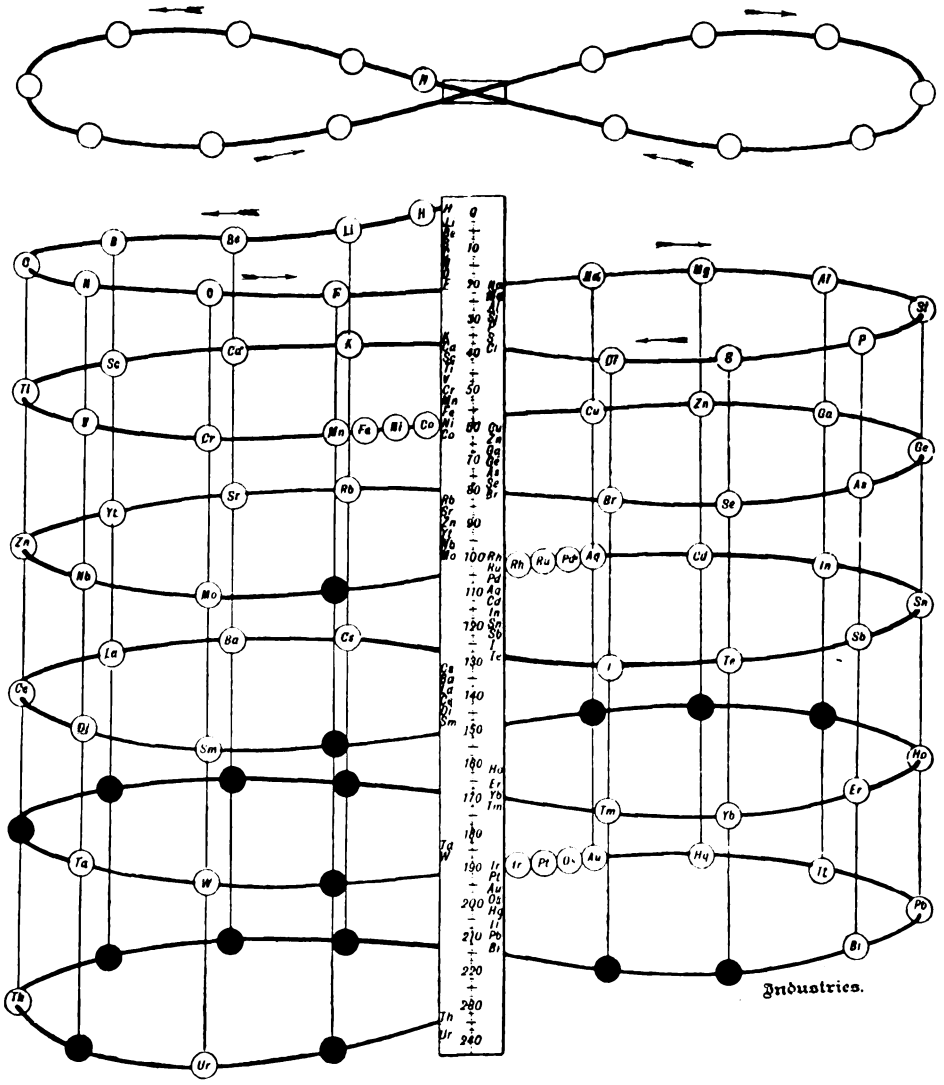
separator which we herewith illustrate. The machine was designed by Mr. Holroyd Smith, of Halifax, for use in the potteries. The material required for the manufacture of pottery, be this ordinary earthenware or porcelain, contains, besides china clay, also other substances, of which powdered flint is one. Flint is so hard that it has to be calcined before it can be crushed and reduced to the impalpably fine powder necessary for the potter's work, and the machine which used to be employed for the reduction, the "slipper mill," was found to be so slow in its action that potters have lately resorted to various more modern disintegrators or other pulverising machines. This change, although accelerating the work, has brought with it the serious evil that considerable quantities of metal are ground off the working parts of the machine at the same time that the flint becomes pulverised, and these small particles of metal become so thoroughly mixed with the flint as to make it almost unsuitable for the better class ware, because the iron produces stains and streaks in the china. It therefore became necessary to treat the powdered flint after it had passed through the pulveriser in some apparatus which would remove even the finest particles of iron. The question was taken in hand by Mr. Thomas Malkin, the proprietor of the Legal Mills, Burslem, who determined to put down a pulverising plant; but before doing so he had some flint pulverised by the maker of the plant, and he submitted the samples of the material so obtained to various makers of magnetic separators, to see whether their machines would efficiently treat this stuff. Existing separators, although they were able to extract nuts, washers, nails, turnings, &c., out of coarse grained non-magnetic material, were utterly unfit to deal with the very small particles of iron when intimately mixed with impalpable flint powder. Mr. Malkin then consulted Mr. Holroyd Smith, who undertook to design a machine specially for this purpose, and which we illustrate herewith.

The leading idea of the design is to bring the material into the closest possible proximity to the magnet poles, and for this purpose it is thrown against a series of poles by means of a revolving bell D, mounted upon a vertical spindle, which receives motion by a pair of bevel wheels and rope pulley on the top of the machine. As will be seen from our illustration, the machine is intended to be

Elevation and Plan.

fixed to a wall, and is provided with a spout and hopper A, into which the material is poured. The revolving bell is surrounded by two sets of electromagnets M, arranged in semi-circular casings *a*, which are hinged at the back, so that they can be opened for inspection. The poles are a series of triangular iron blades, the top row consisting of several plates, so as to present as many edges as possible. As the material passes by these poles the iron particles are retained, and cluster round the edges, whilst the flint powder falls into the second hopper B, and passes over a second bell and by a second set of electromagnets in the lower casing, where any particles of iron which might have escaped the first set of magnets are retained. The purified powder is finally discharged through the spout C into sacks. The magnets are energised from secondary batteries, or from a separate little dynamo, or from the lamp circuit, if the factory should possess an electric lighting plant. Ingenious self acting switches are employed, by means of which the exciting current is interrupted when the magnet casings are opened. These automatic switches consist of springs *b* and *c* for the upper magnets, and *d* and *e* for the lower magnets, which meet contact pieces D and E when the casings are closed, but which leave them when the casings are opened. By this means the current is interrupted automatically each time the casings are opened, and as thereby the magnets lose their carrying power, the iron dust which previously adhered to the poles falls off or can be brushed off. The percentage quantity of iron contained in the material is very small, and a considerable quantity of material can therefore pass through the machine before it is necessary to open and brush out the casings. The rate of feed can be adjusted in accordance with the nature of the material to be treated, by raising or lowering the bell D; and the best speed for the vertical spindle is about three hundred revolutions per minute. When we saw the machine at work there was a marked difference in the appearance of the material fed in at the top and passing out at the bottom, whilst the particles of iron brushed out from the magnets formed a very fine powder. So far as can be judged from a casual inspection, the machine appeared to do its work thoroughly well, and we are informed by the inventor that one of these machines has lately been supplied to a pottery in East Liverpool, Ohio, where it was submitted to the following test: A small sack of pure powdered flint was mixed with half an ounce of powdered iron, and the mixture was passed through the machine, when in the first passage 75 per cent. of the iron was recovered. The machine we illustrate is intended to deal with from 15cwt. to 50cwt. of flint powder per hour, according to the quantity of iron contained and the degree of purity required.

ELEMENTS AND META-ELEMENTS.



In reviewing the progress in the science of chemistry during the past year, at the anniversary meeting of the Chemical Society, the President (Professor W. Crookes, F.R.S.) called the attention of the Fellows present to the recent important work of Drs. Krüss and Nilson on the so-called rare earths, and the investigations of Grünwald on the spectra of the elements, whose work foreshadows the conclusion that hydrogen, oxygen, carbon, and magnesium are not simple, but compound substances. Mr. J. A. R. Newlands, who first pointed out the periodic nature of the elements, has at last received public recognition of the importance of his work by the Royal Society. The President was of opinion that we are now on the dawn of some epoch making, far reaching discovery concerning the nature of matter and the relations which exist among the elements. In previous communications at the British Association, and elsewhere, Professor Crookes has unfolded the views which he entertains concerning the nature of the elements, and has shown how his own work on the rarer elements supports the conclusions to which he has come. It is difficult when dealing with these substances to draw a line of distinction for an element; and he asked the question: "Are we going to open the portals and admit as an element every applicant, or make the examination a stiff one, so as to exclude all but sixty or seventy?" Among the known elements it is easy to distinguish and separate them when their basicity is different, or when their bascity is the same and when there is a marked difference in the colour of the salts, as in the case of nickel and cobalt; but when we meet with elements with the same degree of basicity unaccompanied by a marked difference in physical properties, it was extremely difficult to distinguish them, and in some cases, as in those which he himself had worked at, a difference in phosphorescent spectra alone was all that could be found to distinguish between them. The difficulty of accurately defining an element, in the present uncertain state, fades away if for an element we read an elementary group, and if we consider that there may be several different kinds of matter, all possessing nearly the same atomic weight, and have very similar degrees of basicity. Such a complex group of elements we have hitherto considered an element; but he has shown that in some cases, by a series of laborious separations by fractional precipitation of the bases from their salts by means of ammonia, it is possible to sort elementary yttrium into different kinds. The action which takes place is of a selective character, the elements present differ very slightly in their basicity, and the more basic are those which are first precipitated on rendering the solution alkaline. By repeated precipi-

Digitized by Google

tations the basic constituents are sorted from the less basic, and after "many hundred times we educate the atoms, drawing out properties previously masked."

The evolution theory of the origin of these elementary groups from the vibratory protyle may be compared with the formation of small crowds of people in a crowded street in which each person has his own rate of movement and direction. A finely divided powder falling through water separates into different groups, owing to the slight differences of specific gravity, and each of such groups is comparable to an elementary group. A similar kind of sorting goes on when rarefied gases are subjected to an electrical rhythmic action. In space in the same way the elements and cosmic masses have probably been formed from the protyle of primary motion. This primary matter was at a high potential, and in running down, a secondary motion was produced, causing aggregations and polymerisation of the primary matter into elementary groups. These elementary groups would likewise form molecular and molar groups of greater complexity and less potential, the ultimate final size being determined by the loss of potential which the primary protyle has undergone. The element chlorine may be viewed as a grouping of atoms round one centre, of which the mean density is 35·5; but some of the atoms may have a higher and some a lower atomic weight than this, some having a weight which is only a little below that which would be attracted towards the nucleus whose mean weight is 80, and which we call bromine. The elements having similar properties and weights intermediate between bromine and iodine will be similarly drawn towards the centres 80 and 127. Didymium has recently been split up into two component elements, praseo- and neo-dymium, and it is probable that all the elementary groups might be similarly resolved into their components if we could find the right way of attacking each individual problem. In the accompanying zig-zag diagram, the formation of the elements in a periodic manner, from the primary protyle, gradually losing its potential, is shown. The representation in space of three dimensions instead of the pendulum figure which the author has been in the habit of using in his previous discourses, better illustrates the variation in properties and the periodic nature of the elements. In the first cycle from hydrogen (1) to chlorine (35·5) space and electricity remain the same during this period; but the temperature has fallen, causing the cycle not to return to its original starting point. If the temperature had not changed, or the potential had not been lowered, the first cycle would have been repeated, instead of a second period of elements of lower temperature values but of similar properties to the first cycle from potassium (K=39) to bromine (Br=80) being produced. The groups of similar properties will thus be situated on vertical lines, forming, as it were, pillars to the walls of the winding staircase. In the centre is a scale showing the gradual increase in atomic weight for the different periods. There is not necessarily any waste of energy in the universe, if the particles of secondary motion have their energy transformed into energy of primary motion at the confines of space. In conclusion, Professor Crookes expressed the hope that others would study the problem, and that the truth which, he had no doubt, underlay these speculations might soon be found.

ELEMENTS AND META-ELEMENTS.

Notes.

RAMIE FIBRE.

General L. Sewell, of New Orleans, in a report containing some practical information on the culture of the ramie plant, attributes the difficulty of obtaining a good supply of the fibre to the error of attempting to decorticate the plant when in an unripe state. He also states that none of the machines he knows of have the power to fibrise the ramie stalk when at its maturity. Consul de Fonblanque, of New Orleans, reports, however, that a Scheifner decorticator has since been imported from France and works well; but, unfortunately, a sufficient quantity of ramie to make a thorough test of the machine could not be obtained. As matters stand, farmers will not plant the crop, because they think that the machinery for utilising it is not perfected; on the other hand, the machinery cannot be perfected until there is enough of the raw material to test it with.

A NEW SUGAR CANE.

The *Times* states that for about one hundred years most of the sugar in the West India Islands has been obtained from the Otaheite cane, originally brought from the Pacific Islands by Captain Bligh in His Majesty's ships in 1796. Latterly strenuous efforts have been made to introduce new canes, in the hope that they would prove richer in yield of sugar. In one instance it is stated that a cane introduced by the present Assistant-Director of Kew Gardens, when in charge of the Botanical Gardens at Jamaica, has supplanted the Otaheite cane, and proved most productive. A planter at St. Kitts says the new cane, which he has called the Jamaican, is a "marvellous cane." He adds that "it stands dry weather well, and is entirely superseding the Otaheite cane."

ANNEALING STEEL BOILERS.

Our American contemporary the *Marine Journal* publishes the following account of a process for annealing steel boilers. It states that "a discovery of great importance to steamship and steamboat owners has recently been made by George V. Sloate, superintendent engineer of the Old Dominion Steamship Line, New York. It is a well known fact that steel plates forming the furnaces and connections of marine boilers after a few years' use become crystallised, and crust to such an extent that in many cases they have to be renewed at great expense. By using Sloate's process of annealing about once every three years, the metal is fully restored to its normal condition, viz., full strength, ductility, and proper reduction of area when tested. This treatment will insure the furnaces and connections lasting as long as the boiler. Boilers with the advantage of surface condensers should, with proper management and care, give twenty years of actual service, with moderate cost for repairs. The furnaces of the steamships 'Roanoke' and 'Guyandotte,' after five years' service, commenced to crack over the bridge walls to such an extent that the company had to renew two of them on each ship. Upon examination, it was found that the steel in the old furnaces had become crystallised, and was as brittle as cast iron; in fact, it resembled the latter more than the original steel. By heating it to a mild red heat, and afterwards allowing it to cool off gradually, the apparently worn out metal was restored to its original condition and tensile strength. Thus it was that Mr. Sloate conceived the idea of heating and annealing it. The work of accomplishing this object is very simple. The boiler is emptied of water, all manhole and handhole plates are put on, and the boiler is hermetically sealed. Before closing the furnace doors, a bridge wall is built up within 3in. of the furnace all round. After this a form is made of boiler iron, 2ft. less in diameter than the furnace, and about 3ft. long. The space between is then filled with chemical or tinder dried wood, after which the ash pans are closed, and the fires lighted. When a red heat is reached, the dampers are closed, and all air excluded from furnaces. The fire burns slowly for from twenty-five to thirty hours, and after all the wood is consumed the furnace is allowed to cool off gradually. Upon opening the furnaces the steel is found to have become annealed and restored to its normal condition without any injury to the boiler or loss of time to the ship. The boilers of the steamships 'Seneca' and 'Guyandotte' have undergone this treatment, thereby saving the owners the expense of repairing the furnaces."

THE MAXIM GUN.

The Maxim Gun Company has just issued a portion of the official report of the Austrian War Office of the trial of this new weapon. The report is extremely favourable. The preliminary trials of last July established the superiority of the Maxim system over all others, both as regards rapidity of fire and ease of manipulation, and thereupon the Austrian Government ordered exhaustive experiments to be made, which included tests for range and accuracy at distances from 200m. to 1575m., and tests for strength and durability. The results showed that the accuracy of the Maxim is superior either to the two-barrel Gardiner or the five-barrel Nordenfelt. For testing durability, series of 334 rounds, fired consecutively, were almost exclusively used, and an average speed of ten rounds per second was obtained, not only with the greatest elevation and greatest depression, but also when traversing the gun laterally through the greatest angle that the mounting would allow. In all 13,504 rounds were fired, and the report states that on the whole the gun behaved extremely well, the loading and firing mechanism operated faultlessly, and if certain reserve parts are supplied, and the buffer spring made stronger, the durability of the weapon would be guaranteed under all circumstances. After 6356 rounds had been fired, the weapon was tried for accuracy, at a target 2m. by 3·6m., at 600m. range, and an excellent diagram obtained. The 11mm. rifle cartridge (model of 1877) was used, and trials of the barrel with English "Henry" rifling did not show any advantage over that of the Werndl barrel. The report is signed by Colonel H. Huffzky.

Patent Record.

Compiled from "The Official Journal of the Patent Office," by W. E. Heys, *70, Market-street, Manchester.*

APPLICATIONS FOR PATENTS.

(The names in italics within parentheses are those of Communicators of Inventions.)

ENGINEERING.

31st March, 1888.

4838. Richardson, H. F. ..... Beater bars used in threshing machines (*Woolnough*).
4841. Wilson, J..... Improvements in walls, buildings, silos, bins, warehouses, forts, batteries, theatres, safes, strong rooms, ships, barges, and other vessels, bulkheads, partitions, shields, tanks, vats, vehicles, refrigerating safes, houses, and fire proof screens.
4846. Rogers, S. A..... Tramway cars.
4850. Jucker, J..... Power looms.
4851. Kilbourn, J. K..... Compression pumps for gaseous fluids.
4855. Jones, W. P..... Cartridge ramming, crimping, and closing press.
4858. Smith, J..... Brakes for tram engines.
4859. Yewdall, W. H. ..... Writing machines.
4860. Abraham, J. F..... Recording the flow of water and the pressure of steam in pipes.
4861. Taylor & Warburton. Manufacture of figured fabrics.
4862. Holt, T..... Reeling machines.
4863. Sinnatt & Humphreys. Manufacture of stoppers for bottles.
4865. Barlow, C. A. ..... Moving boats from one canal on to another.
4867. Hughes, F. J..... Automatic car coupler.
4875. Wilson & Tafe..... Raising and lowering submarine telegraph cables.
4877. Prince, J. ..... Metallic dies for brick and tile making.
4883. Murgatroyd, E. ..... Wheels of carts.
4884. Thomson, W..... Wheel axles of tram cars.
4886. Forder & Forder ..... Hansom cabs.
4887. Figge, A..... Cleaning vegetable fibre.
4888. Turrettini, F..... Endless saws for cutting stone.
4889. Holmes, R. J. P. G..... Machine comprising a combination of tools.
4893. Read, H. V. R..... Sugar cane mills.
4894. Dobroff, S., & others... Manufacture of woven fabrics.
4896. Campion, W..... Seaming machine.
4897. Campion, W..... Turning-off machine.
4902. Lake, H. H..... Railway ties (*Sea*).
4904. Howard, J., & others... Straw trussing and sheafing machines.
4907. Sander & Hoffmann... Manufacture of checkered yarns.
4910. Chatwood, S., & others. Safes, strong rooms, and locks.

3rd April, 1888.

4917. Roberts, H., & others... Removing the scale from steam boilers, &c.
4918. Clyne & Mitchell..... Apparatus for polishing stone.
4919. Clegg & Moorhouse ... Self acting mules.
4920. Melling, J. W..... Valve gear.
4922. Gallon, W..... Breaking and beating engine rolls and elbow plates.
4923. Beck, I. ..... Punching machines.
4924. Ruck, H..... Pressing and tying up straw, hay, and flax into bundles.
4925. Smith & Smith ..... Jacquard machines.
4926. Seyfert & Donner..... Knitting machines for making plush.
4928. Bardsley & Johnson... Brakes and winding and drawing apparatus.
4932. Gilchrist, G..... Thrust blocks for screw propeller shafts.
4933. Lee & Croll..... Shuttle picking for looms by means of compressed air.
4934. Reaney & Blakemore.. Colliery cages.
4938. Priest, E..... Feeding slivers of wool to carding machines.
4939. Eaton & Birch..... Machinery for rubbing types.
4944. Wilson, A..... Combined gas engines and gas producers.
4951. Lindenthal, G..... Refining iron.
4956-7. Moseley, J..... Apparatus for making cards for carding fibrous materials.
4961. Boult, A. J. ..... Steam boilers (*Rushton*).
4963. Beardsley, G., & others Apparatus for carrying the bobbins of traverse warps.
4965. Caulfeild, F. St. G..... Maintaining submerged mines at a given distance from the surface of the water at all states of the tide.
4968. Papleux, J. ..... Apparatus for ungumming rhea.
4970. Stitzel & Weinedel ... Semaphore signalling apparatus.
4973. Dowling, J. P..... Presses for hay, straw, and wool.
4975. Warner, A. M..... Manufacture of iron.
4976. Noble, A. ..... Breech loading guns.
4978. Lake, H. H..... ..... Machines for pulverising ores (*Gates*).
4980. Sohn, A. H. ..... Dams.
4981. Jarvis, S. E..... Steam engines.
4984. Edwards, E..... Presses (*Gayon*).
4986. Appleby & Abrahams.. Machinery for stamping mineral ores.

4th April, 1888.

4993. Bland, J. ..... Washing, wringing, and mangling machines.
5000. Swanson, W. M..... Floating docks.
5004. Mitchell, W. ..... Propelling ships.
5007. Jucker, J..... Testing top rollers of spinning machines.
5009. Cartwright & Cartwright..... Self indicating weighing machines.
5012. McDougall, I. S..... Heating feed water.
5016. Thompson, W. P..... Rolling tubes and columns from hollow ingots and piles (*Kellogg*).
5018. Robertson, J. ..... Manufacture of metal tubes.
5021. Cheevers, J..... Apparatus for measuring granular materials.
5023. Collingbourne & Roe. Ball bearings.
5027. Lawrence, R. S. ..... Shells containing high explosives.
5033. Wilson & Pirrie..... Ships.
5034. Nordenfelt, T..... Machine guns.
5035. Schmidt, C. A. G..... Washing, dyeing, and bleaching textile materials.
5038. Haddan, R. ..... Dyeing skeins of textile material (*Decock*).
5040. Merryweather and Jakeman..... Fire engines.

5th April, 1888.

5048. Fletcher, J. M. ..... Engines.
5050. Unwin, F. ..... Tension pulleys.
5051. J. T. Hailwood ..... Lubricators.
5052. Rose & McLellan ... .. Looms for weaving fire hose.
5053. White & Wallbank ... Combustion of gases in steam generator furnaces.
5054. Burt, P. ..... Wringing machines.
5057. McDougall, I. S. ..... Steam generators.
5058. McDougall, I. S. ..... Securing tubes in tube plates and flanges.
5060. Lynde, F. C..... Spindles and flyers used in twisting and winding machines.
5062. Radcliffe, F. ..... Revolving furnaces for roasting cement.
5065. Rose, G. ..... Force pumps for use with spray, vapour, and other oil lamps.
5070. Jenkinson, T. ..... Roller bars and rag engine bottom plates.
5076. Birkett, I. R. E. ..... Hoists for warehouses.
5081. Winter, J. ..... Forge cranes.
5083. Walker, J. A. ..... Generating steam by liquid fuel.
5084. Twynam, T. ..... Manufacture of ingot iron and steel.
5085. Pellas, E..... Balanced lug sail.
5088. Walker, T. J. ..... Heating fluids.
5089. Campbell & Campbell Masts of ships.
5094. Hasted, G. ..... Thrashing machines.
5095. Bentall, E. H..... Lawn mowers.

ELECTRICITY.

31st March, 1888.

4844. Thompson, W. P. ..... Incandescent electric lamps (*Garczynski*).
4909. Fell, J. C..... Telephonic apparatus (*Otzen*).

3rd April, 1888.

4929. Gillett & Haseltine.. Magneto-electric generators.
4940. Parker, T. ..... Alternating current dynamo-electric machines.
4945. Proctor, C. F..... Coupling alternate current electric machines.
4964. Boult, A. J..... Regulating electric currents (*Doubrava*).

4th April, 1888.

5029. Morsby & Davies ..... Generation of electricity by tidal or river power.

5th April, 1888.

5069. Randall, C. A. ..... Mechanical and electromagnetic motor.
5082. Sellon & Jackson ..... Electricity meters.
5098. Kricboom, P. L. ..... Electrical signalling in connection with telephone circuits.

CHEMISTRY.

31st March, 1888.

4842. Jarvis, G. A. ..... Manufacture of sodium or potassium.
4843. Staveley, W. W..... Carbonates, sulphites, bisulphites, or hyposulphites of the alkalis, and phenol.

3rd April, 1888.

4959. Lewis, J. J. ..... Extraction of ammonia from tar water.

4th April, 1888.

5031. Selwyn, J. H. ..... Extraction of metals and production of nitric acid.

5th April, 1888.

5086. Donald, W. J. A..... Manufacture of chromates.

MISCELLANEOUS.

31st March, 1888.

4847. Rogers, S. A. ..... Apparatus for winding "Waterbury" watches.
4848. Prestwich, W. H. ..... Draught regulator for stoves.
4849. Howard, J. ..... Check tills.
4853. Taylor, W. .... Fire extinguishing apparatus.
4854. Powell & Dickinson ... Skinners' knives.
4856. Donovan, E. W. ..... Self regulating valve.
4866. Sanders, A. ..... Lamp fittings.
4868. Wilson, T. ..... Water taps.
4870. Brown & Mackenzie ... Door springs.
4871. Stuart & Young ..... Regulating the surface flow of liquids from tanks.
4881. Robertson, W..... Velocipedes.
4885. Dinsmore, J. H. R. ..... Manufacture of gas.
4890. Alexander, A. E. ..... Roasting coffee by superheated steam (*Cardozo*).
4892. Hazeldine, J. T..... Glass houses.
4895. Slazenger & Matthews Manufacture of boots.
4899. Schmidt, M. von..... Treatment of fatty substances for candles.
4903. Lake, H. H. ..... Barrels (*Cooke & Alvord*).
4906. Schroeter, W. ..... Bicycles.
4911. Hitchcock, R. ..... Fences.

3rd April, 1888.

4915. Avis, W. H. ..... Twisting and laying twines and cordage.
4916. Southall, R. H. ..... Paring the soles of boots.
4931. Turnbull, J..... Boiling esparto grass.
4941. Rice, W. H. ..... Rowlocks.
4947. Bailey, T. ..... Fire proof partition.
4949. Dick, R. ..... Manufacture of boots.
4953. Westphal, C. ..... Production of water gas.
4954. Hart, A. ..... Decanting the contents of oil cans.
4966. Petrie, G. ..... Taps.
4967. Wallis, H. E. A..... Liquid basins for gas governors.
4971. Kertsch, C. ..... Apparatus for preventing waste of water.
4977. Dutton, S. T. ..... Regulating the charge supplied to the oil cisterns of railway signal, carriage, ship, and other lamps.
4982. Duggan, J. ..... Lamps.
4983. Dehany, G. E. ..... Extinguishers for lamps.
4989. Beck, W. H. ..... Devices for winding clocks (*Diette and Hour*).

4th April, 1888.

4995. Lindsay, R. ..... Briquettes.
4997. Bunting, S. ..... Stoppering of bottles.
4999. Musselwhite, W. ..... Safety tap for effervescing liquids.
5001. Fahie, A. ..... Apparatus for counting boards, planks, rails, &c. (*Nielsen*).
5003. Weston, T. R. ..... Safety lamp.
5006. Ballardie, D. ..... Lamps.
5008. Phillips, J. H..... Vehicle with advertising attachments.
5010. Oliver & Hethering-ton..... Production of moulded wood articles.
5013. Tate, J. W. ..... Lamps.
5017. Paton, J. M. C. ..... Manufacturing gas for heating and illuminating purposes from molasses (*Van Dyk & Wilkinson*).
5020. Downie, T. ..... Metallic packings.
5022. Hutchins, H. E. ..... Rack pulleys.
5026. Reeve, J. T. ..... Receptacles for powdered matters.
5028. Eades, W. S..... Manufacture of boots.
5030. Newton, P. A. ..... Cock for conduit pipes (*Christopherson*).
5032. McNish, J..... Glazing paper and textile fabrics

5th April, 1888.

5044. Blagden & Slaytor ... Automatic measuring taps.
5045. Ross, J. H. ..... Lamp clock.
5047. Allen, J. J. ..... Gumming, pasting, & damping apparatus.
5059. Beesley, J. ..... Velocipedes.
5061. Müller, H. ..... Safety fuse.
5063. Kilsby, W. ..... Lamps.
5067. Carpenter, J. ..... Pendulum clock.
5068. Tautz, F. G., & others... Manufacture of hats, caps, and gloves.
5071. Bullen, J. ..... Apparatus for emptying carboys.
5072. Knowles, E. ..... Valves employed in sprinkler installations.
5079. Birkett, J. ..... Paving blocks for street crossings and gutters.
5080. Knowlton, M. D..... Manufacturing boxes of paper, straw, board, and wood. (Received 5th April, 1888 Ante-dated 14th February, 1888, under International Convention).
5090. Heimsoeth, B. ..... Locks.
5091. Chambers, G. J. ..... Earthenware bottles.
5092. Cunliffe. W. ..... Lamps.
5097. Vavasseur, J. ..... Cartridges for ordnance.
5100. Stark, J. ..... Velocipedes.

COMPLETE SPECIFICATIONS ACCEPTED.

Persons interested in opposing the grant of the following patents may give notice of opposition at any time within two months after the dates given.

ENGINEERING.

7th April, 1888.

17010. Lake, H. H..... Button hole sewing machines (*Wheeler*).
4754. Gorgeon, N. J..... Apparatus for crushing and grinding.
4786. Riley, G. ..... Circular knitting machines.
4912. Gandy, M..... Textile belts for driving machinery.
5674. Newall & Blyth ..... Steam engines and pumps.
5730. Metcalfe & Davies ... Injectors.
5837. Edwards, E..... Self acting spinning machines (*Schneider*).
6045. Fox, S. ..... Manufacture of tubular parts of steam boilers.
6235. Watts, J. W..... Circular latch needle knitting machines.

Digitized by Google

6351. Cranston, W. McI..... Binding mechanism of harvesting machines (*The Walter A. Wood Mowing and Reaping Machine Co.*)
6397. Edwards, E..... Apparatus for measuring water.
6455. Leuty, J. E..... Compressing ensilage stacks, hay, trusses, and bales.
6585. Walsh, E. Y..... Loom pickers.
6701. Thwaite, B. H., & others Portland cement.
6925. Obach, T. ..... Endless wire ways.
6973. Hall & Parry..... Machines for making casks.
7134. Gürtler, W..... Structures formed of asphalt and metal frame work.
7348. Stayner & Roberts ... Manufacture of coke forks.
7367. Parkes, G. W. ..... Automatic time keeping apparatus.
7460. Williamson, T., & others Turning over ingots on feed rollers.
7558. Whitaker, A. ..... Gearing for extension rails of railway turntables.
7828. Lloyd, G. H., & others.. Welding boiler flues.
7840. Pegden, J. B. ..... Steam steering gear.
7916. Dewar & Mair..... Washing machines.
7917. Hahlo, C., & others ... Pattern mechanism for looms.
7925. Wallwork & Sturgeon Gas engines.
7938. Hipkins, T. ..... Steam boilers.
7946. Oliver, W. S. ..... Sewing machine.
7947. Boothby, A. C..... Movable stern dock for screw steamers.
7948. Boothby, A. C..... Cleaning the bottoms of iron or steel vessels.
7964. Anderson & Pollock... Sewing machines for button holes.
7997. Ashenhurst, T. R. ..... An improved figured cloth.
8017. Sommerfeld & Hensel Sewing machines.
8052. Noble & Murray ..... Disappearing gun carriages.
8053. McEvoy, C. A. ..... Firing mechanism fuses for the ignition of cartridges in guns.
8060. Smith, F. H..... Preventing accidents in shafts, hoists, or elevators.
8160. Wood, J. ..... Paper making machines.
8276. Dowie, A. L..... Treating iron and castings.
8492. Quénéhen & Vansteenkiste..... Apparatus for grinding.
8550. Shapton, W..... Cranes for working grab buckets.
8628. Newton, H. E..... Sewing machines for button holes (*National Machine Co.*).
8860. Gauhe, O. W. ..... Detachable elevator chain.
9123. Tschörner & Wein..... Looms for the manufacture of damask.
9910. Leigh, H. H..... Table for guillotine machines (*Simoulin*).
10659. Thompson, W. P..... Converters (*Robert*).
10896. Colclough, W. A. ..... Mounting the bodies of vehicles.
11515. Lindsay & Allan ..... Shaping the teeth of bevel wheels.
11806. Bland, W..... Machines for taking copies of written or printed matter.
12013. Allison, H. J. ..... Apparatus for copying writings and designs (*Sanders.*)
14617. Clark, J. ..... Metallic belts for conveying coal.
16080. Moore & Palmer ..... Manufacture of hosiery.
17677. Griffiths, W. J..... Holding and guiding twist drills during grinding.
690. Aniello, J. A. ..... Lifeboat.
2154. Martin, M., & others... Apparatus for dressing hides and skins.
2540. Allison, H. J. ..... Chaff cutters (*Stout & Underwood*).
2571. Boult, A. J. ..... Car couplings (*Brown*).
3270. Winder, R. ..... Type composing machines.
3337. Windrath & Hausmann Reed for looms.
3347. Matthews, S. ..... Water gauges for steam boilers.
3474. Edwards, E..... Automatic starting and braking apparatus for cars (*Feenel*).

ELECTRICITY.

7th April, 1888.

6104. Foster & Anderson ... Electrical measuring instruments
6219. Swinburne, J..... Induction apparatus.
7184. Mackie, W. ..... Electric arc lamps.
7950. Smith & Jackson..... Telephones.
7982. Fitzgerald, C. L. W.... Telephonic instruments.
8159. Smith, W. ..... Telegraphic communication to lighthouses.
2179. Wheeler, M. ..... Incandescent electric lamps.
2246. Lake, H. H. ..... Dynamo-electric machines (*Fickemeyer*).
2250. Linville, J. H. ..... Printing telegraphs.
2308. Coerper, C. ..... Dynamo-electric machines.

CHEMISTRY.

7th April, 1888.

5124. Wells, G. I. J..... Evaporating liquors containing salts (*Pick*).
7812. Liebmann & Studer ... A new mono-sulpho acid of alpha-naphthol.
7998. Kennedy & Green ..... Apparatus for washing ores.
9363. Jacquemin, G. E..... Manufacture of wine from barley.
3393. Milligan, T. P. ..... Production of gelatine, glue, and size.

MISCELLANEOUS.

7th April, 1888.

4773. Boult, A. J..... Door checks and closers (*Elliott*).
4862. Darling, J. ..... Needle threader.
4876. Boult, A. J..... Files (*Custer, Napier, & Napier*).
5262. Simmons & Simmons ... Lithographic and letterpress rollers.
5792. Sparrow & Osgerby.... Automatically regulating the supply of gas.
6936. Heffter, P. J. E..... Clarifying and saturating sugar solutions by tannic acid.
7018. Fletcher & Clare..... Apparatus for automatically controlling the supply of gas to atmospheric gas burners.
7517. Tyzack, T..... Saws.
7907. Barthel, A. E..... Fluid reservoir.
7980. Klic, K..... Treatment of paper for drawing purposes.
8002. Granger & Alvey ..... Signalling between passengers and guards on railway trains.
8011. Nicholas, A..... Call bells.
8031. Gould, R. ..... Composition for distempering.
8198. McMullen, W. J..... Dust bins.
8334. Nicholls, J..... "Silver cleaning" paste.
8835. Fry, L. A. ..... Decorating clay ware.
9259. MacMahon, C. ..... Fire escape.
10034. Smith, R. ..... Chimney pots.
11032. Reid, J..... Pantograph drawing instrument.
14169. Hicks, J. J. ..... Hydrometers & saccharometers.
15107. Horn, W. W. ..... Argand burner (*Dodd*).
15889. Grimbleby, T. N. ..... Roofing tile.
16366. Baker, F. R..... Oil lamps.
691. Martinson, O..... Measuring & drawing off liquids.
838A. Sayer, R. C. ..... Filters. (This Application having been originally included in No. 838, dated 19th January, 1888, takes, under Patents Rule 23, that date.)
2356. Butler & Stanton..... Velocipedes.
3019. Goode, C. P..... Portable compressed forage.
3156. Lawrence, H. ..... Chimney cowl.
3255. Wheatley, W. T. ..... Cement for securing the handles of cutlery.
3412. Birkbeck, H..... Wind vanes (*Mattison*).
3468. Boynton & Johnson ... Bobbins for spinning machines.

PATENTS VOID THROUGH NON-PAYMENT OF RENEWAL FEES.

(To the 31st December, 1887, inclusive).

Year 1883.

5859. Brookes, A. G..... Augurs (*Swan*).
5865. Warburton, E. C., & ano. Dynamo-electric machines.
5866. Lake, W. R. ..... Printing presses (*Nowell*).
5868. Weldon, W. ..... Manufacture of chlorine.
5871. Hartley, J. W. ..... Locomotives.
5873. Henderson, N. McF. ... Obtaining oil and gas.
5874. Brandon, R. H. ..... Electrical conductors (*Campbell*).
5876. Brandon, R. H. ..... Compressing rods, &c. (*Billings*).
5880. Greenwood, A., & ano. Sewing machines.
5883. Keywood, F..... Knitting machinery.
5884. Wood, E. M..... Greenhouses.
5885. Brookes, A. G..... Signalling by electricity (*Downs*).
5886. Glaser, F. C. ..... Treating zinc ores (*Erben & ano.*)
5887. Haddan, H. J. ..... Expansion wrenches (*Lytle*).
5888. Paddock, W..... Rotary engines, &c.
5892. Greenwood, A. ..... Sewing machines.
5893. Imray, J. ..... Distilling, &c., liquids (*Egells*).
5894. Imray, J. ..... Vessels exposed to corrosive action (*Egells*).
5900. Lake, W. R. ..... Steam engines (*Porter*).
5901. Hill, O. W. F. ..... Imparting motion to parts of mechanism.
5902. Scott, D..... Production of patterns.
5903. McCulloch, J., & ano... Obtaining oil.
5904. Stott, D. ..... Production of patterns, &c.
5906. Wylie, R. P..... Raising sunken vessels, &c.
5907. Stevenson, G. ..... Steam boilers, &c.
5921. Beesley, W. T..... Cutting sheets of metals.
5923. Sombart, C. M. ..... Gas engines.
5928. Welch, E. J. C., & ano.. Gas engines.
5929. Campbell, J. ..... Ships' logs.
5933. Heath, W. E. ..... Storing up structures.
5935. Lake, W. R. ..... Repeating fire arms (*Larsen and another*).
5938. Morewood, E..... Coating metal plates, &c.
5939. Danchell, F. H. ..... Electromotor engines.
5942. Newton, G. E..... Lawn mowing.
5943. Howaldt, H. ..... Slide valve for steam engines.
5950. Gill, J. W. ..... Generation of steam, &c.
5952. Dempster, J..... Furnaces.
5954. Green, W..... Treatment of mineral oils.
5956. Wastfield, E. G..... Gas engines.
5962. Haddan, H. J. ..... White lead (*Schmoll*).
5963. Sombart, C. M. ..... Refrigerators (*Moebius*).
5964. Sinclair, D., & another Telegraphic, &c., apparatus.

ABSTRACTS OF BRITISH PATENT SPECIFICATIONS.

Compiled from the Published Specifications by W. E. Heys, *70, Market-street, Manchester.*

ENGINEERING.

Casting Metals under Pressure.—*J. J. C. Smith, Passaic, New Jersey, U.S.A.*—Several improvements are here introduced into the construction of an apparatus described in patent No. 1443 of 1869 granted to B. J. B. Mills. The general arrangement is shown in cross section in the accompanying diagram. The supports B carry the cross bar C, and form guides for the plates D and E. The hydraulic cylinder I is bolted to the sliding table F, which is movable sideways by means of the rack F^1, pinion G, and hand wheel H^1. The plunger I^2 projects above the top of the cylinder I, and it is surmounted by a layer of clay J^4. The cylinder J is made in two halves, which are hinged to I on

one side, and bolted together on the other. An asbestos lining J^5 prevents the heat of the molten metal in J from escaping through the walls, and a washer J^7 serves a similar purpose. The cylinder M is fastened to the plate E in the same manner as I, and is also made in two movable halves. The moulds are contained inside the cylinder M; those in the drawing are intended for the casting of elongated projectiles. In operating the machine the screw L is raised together with the table E and the mould receptacle M. This movement enables the slide F to be moved out of its central position, carrying the cylinders I and J along with it. After the molten metal has been deposited in J, the table F is replaced in its normal position. The screw L is then depressed, so as to form a tight connection between the receptacle J and the flask M. The valve admits the water underneath the plunger I^2 after the moulds are in position, and the metal is forced up into the moulds. After the casting is completed the top M^4 is unscrewed, and the flask M is separated into its two parts to facilitate the removal of the castings. Nine claims are made for the construction of the flask M and the cylinder J, for the interior lining employed, and for the disposition of the vessel J.—No. 9322. June 30th, 1887. 8*d.*

Drying Cotton.—*J. D. Sutcliffe, Manchester, and B. T. O'Brien, Liverpool.*—The object of the present invention is to obviate the damaging of the fibre when exposed on the floors of the drying chambers. A series of perforated platforms are arranged one above another, and the material which is placed on them is agitated continually by hand or by power. Steam or hot air pipes are laid round the chamber in which the platforms are erected, and the heated air is caused to circulate through the perforations by means of a Blackman air propeller. When the air has become saturated with the moisture which it has absorbed from the fibre, it is sent through a colder chamber, where the water is liberated and condensed. The same air may thus be used over again several times, and a reduction is effected in the cost of primarily drying, cleansing, and heating the air. Two claims are made for the perforated platforms, and for the manner of circulating the air.—No. 6208. April 28th, 1887. 8*d.*

Sand Moulds.—*O. Jones, London. (S. P. M. Tasker, Philadelphia.)*—This invention relates to an improved method of compressing the sand in the flask containing the patterns. A mass of shot, pebbles, or grains of sand which do not adhere, and are capable of relative motion, is placed upon a flexible presser or diaphragm, and is arranged in combination with an assemblage of rammers which are capable of independent movement, so that when the pressure is applied the surface of the mass next to the flask will conform more or less to the patterns. The yielding pressure is thus more evenly and uniformly distributed through the sand surrounding the various

Digitized by Google

parts of the patterns. Several different methods of carrying out this idea are described in the specification. Six claims are made for this method of compressing the sand through the medium of shot or pebbles, as described.—No. 6750. May 7th, 1887. 8*d*.

Feed Apparatus for Boilers.—*A. Mayhew, London.*—Fig. 1 represents a vertical section of the apparatus, and Fig. 2 illustrates an application of the invention to a steam boiler. The apparatus consists of three cylinders A B C, arranged tandem; the upper two are made in one piece, and form a combined steam and hydraulic cylinder. The main piston A^1 and the loose fitting plunger B^1 extend into the central hydraulic cylinder B; the lowest cylinder C contains a regulating device, consisting of the piston C^1 with a spiral spring S fixed to its

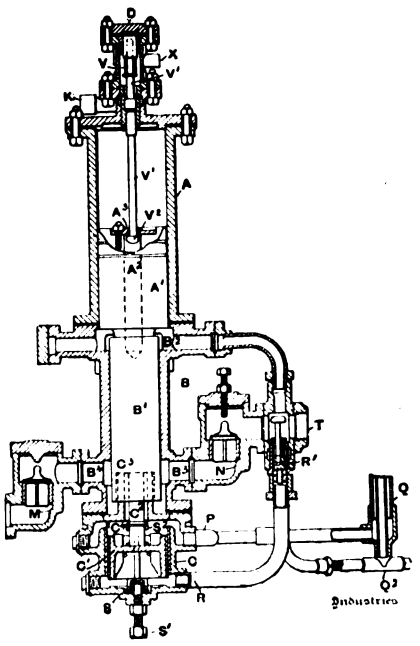

Fig. 1.

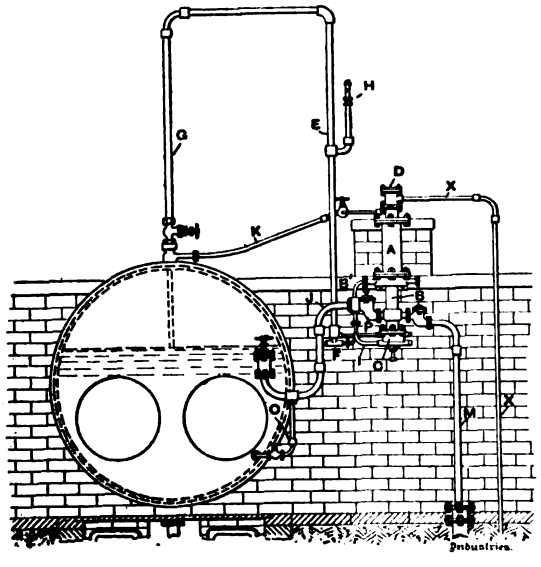
lower side. The weight of A^1 B^1 is made in excess of the pressure against which the apparatus is to act, and the spring S carries the weight of the piston C^1 and of the plungers A^1 B^1. The admission and exhaust of steam takes place through the slide valve V, which is actuated automatically by the main piston and plunger through the spindle V^1. This spindle is furnished with a stop V^2, which works within the main piston in a hole A^2. The valve casing D is connected by a pipe K to the steam space of the boiler, and the exhaust passage X leads to the feed supply. The pipes B^2 and B^3 communicate with the delivery pipe T and the water space of the boiler, and B^4 leads to the feed supply; the suction and delivery valves are shown at M N. The action of the apparatus as applied to the steam boiler is as follows: When all the valves are opened the piston A^1 B^1 descends by gravity and forces the liquid into the delivery pipe T, and the valve R^1 is automatically closed; when the down



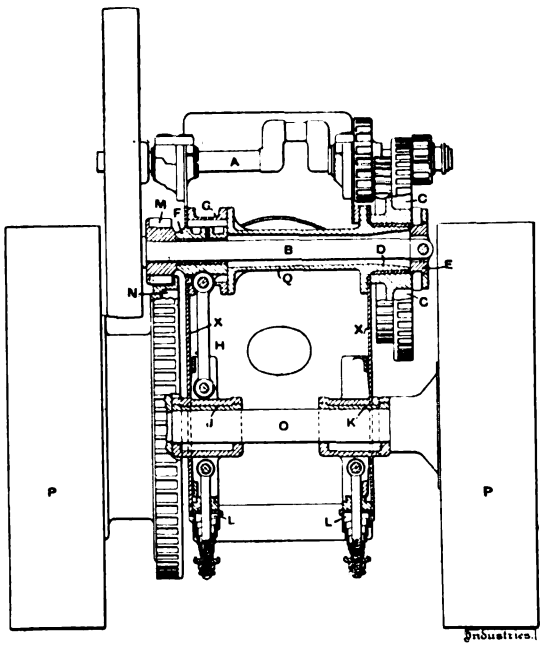


Fig. 2.

stroke is nearly completed, the stop V^2 comes against the plate A^3, draws down the slide valve V, and admits steam to the piston valve. The boiler liquid pressure acting upon the top part of B^1 and the lower side of A^1, forces them up and draws the feed supply through M B^4 into the cylinder B. When the piston has nearly reached the top of its up stroke, the plate A^3 comes against V^1, and raises the slide valve; steam thus enters through K and to the space above the main piston; the piston A^1 B^1 descends and forces the feed supply through T into the boiler. If the liquid in the boiler be at its normal working level the foot of the pipe Q^2 is sealed, and a column of water stands in it; the spiral spring S is now extended, and the rod C^2 passes up into the hydraulic cylinder B, and catching against the plunger, prevents the completion of the down stroke; the apparatus is thus brought to rest. As evaporation continues and the water level falls below the end of Q^2, the column of water falls into the boiler; the steam enters the pipe Q P, and forces down the regulator piston C^1 against the action of the spring S; the operation of the apparatus is then continued as before. Four claims are made.—No. 3729. March 11th, 1887. 8*d*.

Close Annealing Iron and Steel.—*J. E. East, Bilston, Staffordshire.*—The apparatus here described is intended as a substitute for the iron covers, dishes, and other appliances usually employed in close annealing iron and steel sheets. A dish is constructed as a movable platform which will form part of the bottom of the annealing furnace when it is in position. It consists of a cast iron plate, strengthened with ribs on the under side, and is carried on wheels which run on rails. The upper surface of the plate is protected with fire brick, and the cover which is placed over the metallic objects is composed of the same material. Cold air is allowed to circulate underneath the metal plate, in order to preserve it from the injurious attacks of the heat of the furnace. The advantages of this apparatus are that it is easily removable, is cheaper at first cost, and lasts longer than the apparatus hitherto employed. The inventor makes eight claims.—No. 6569. May 4th, 1887. 8*d*.

Hydraulic Lifts.—*B. Turner, London.*—In order to insure the safety of the cages of hydraulic lifts, the inventor suspends the cage by a single rope and connects them by a safety catch which grips the guides. Also two ropes are arranged so as to bear under ordinary circumstances only a slight straining load. These safety ropes are made of the same strength as the main suspending rope, so that if the latter rope should break and the safety catches fail to act, the cage will be suspended by strong ropes which have not been weakened by wear. To prevent the chafing of the three ropes, they are each run over separate pulleys; the ropes, when placed in this way, will not wear out so quickly. Three claims are made for the extra ropes which are not usually in strain, and for the method of arranging them upon the pulleys.—No. 16832. December 7th, 1887. 8*d*.

Traction Engines.—*F. J. Burrell, Thetford, Norfolk.*—The annexed diagram represents a transverse section of a traction engine embodying the present improvements. The crank shaft A transmits motion to the counter shaft B by means of pinions

gearing with the spur wheel C. This spur wheel revolves on the fixed tube D, and is connected to the counter shaft B by a universal joint. The other end of B is carried in a bearing F, which is free to move up and down in the box G. The link H connects F to the axle box J, which is free to slide up and down in the guides S secured to the horn plates X. A pinion M is fixed to the counter shaft, and gears with the wheel N, thus communicating motion to the road wheels P. The wheels M and N are prevented from altering the distance between their centres by the link H, and there is sufficient clearance at the sides of the teeth to allow for the sideway motion of the engine on its springs. An extension Q to the tube D is carried across the engine, and is bolted to the box G, thus forming a solid bearing for the spur wheel C, and a stay between the horn plates X. The inventor makes two claims: (1) For engine mounted on springs and having the counter shaft over the main axle; (2) for coupling one of the main axle bearings to the counter shaft, and connecting the opposite end of the counter shaft by a flexible coupling to a spur wheel mounted loosely on the fixed tube for the purpose described.—No. 5747. April 20th, 1887. 8*d*.

Valve Gear.—*W. Payton, Richmond, Surrey.*—The slide valve is operated by a mechanism attached to the cross head and connecting rod of the steam engine, and the usual eccentrics are dispensed with. A lever is pivoted at one end to some fixed part of the engine, and its other end is connected by means of a pin jointed rod to the cross head. The lever is vibrated on either side of a line at right angles to the line of motion of the cross head. A slotted link is fitted to a saddle piece, which is pivoted to the lever at such a distance from the fulcrum that each vibration of the lever moves the link through a distance equal to the travel of the slide valve between the two positions known as "lead." The saddle piece is pivoted to the lever in such a way as will permit the link to vibrate upon its pivots, which are placed near the centre of the slot. The end of the lever which is pin jointed to the rod connecting it with the cross head is provided with a bell crank lever moving on the pin of the said joint. One of the arms of the bell crank lever is connected by a pin jointed rod to an arm attached to the connecting rod of the engine, and the other arm is connected by a pin jointed rod to the above mentioned saddle piece in such a way that the motion of the connecting rod imparts motion to the saddle piece and slotted link. The slot in the link is of a curved shape, and a curved block slides in it. This block is connected to the slide valve by a rod whose length is equal to the radius of the curved slot. When the block is so placed in the slot that the centre of its pin joint is concentric with the pivots of the vibrating link, the motion of the cross head will cause the slide valve to travel from lead to lead only; but on shifting the block to any other position the slide valve will travel through a greater distance; and the engine can be reversed by moving the block from one side of its central position to the other. Two claims are made.—No. 6516. May 4th, 1887. 8*d*.

Pumping Engines.—*J. D. Wardale, Gateshead.*—The engine described in this invention is adapted to pumping matter which is not perfectly fluid, without the valves becoming clogged up. In the annexed diagrams, Fig. 1 represents a vertical section through the steam and water cylinders; and Fig. 2 is a cross

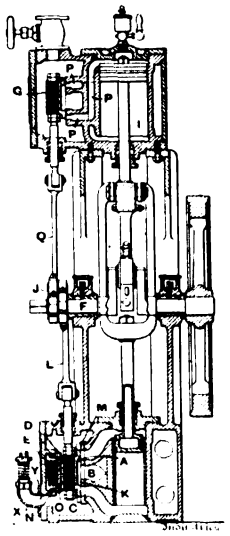

Fig. 1.

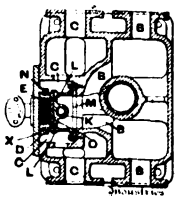

Fig. 2.

section of the water cylinder and valve. The slide valve A is employed to open the suction and delivery passage to and from the pumping cylinder; the inner part K opens to the suction passages at B, and the outer part of A opens to the delivery passages at C. The pressure of the delivery acts upon the back of A, and keeps it against the port faces at M; and any pressure in excess of that which is desirable is taken off the valve by a non-reciprocating box D pressed against the back of the valve by the delivery pressure. The inside of this box is in communication with the suction through the holes L; instead of this, a hole Y may be made for any leakage water to drain out, and in such case the atmospheric pressure would be inside the box. The spring E keeps the box D and valve A against their faces. The box may be of any shape, and is mounted so as to be capable of being pressed forward by the spring. In Fig. 1 it is shown mounted on the part of the casting N, and provided with loose packing rings X. The valve A is worked from the crank shaft F by cams, which also work the valve G. By crossing the ports P of the steam cylinder, so that they open to the valve chest at the ends opsosite to those at which they communicate with the steam cylinder I, one eccentric J can be employed to give motion to the valves of both the steam cylinder and the pump, by the rods Q and L^1. By the application of a slotted link over the eccentric, the travel of the valves may be regulated separately. Four claims are made—for the slide valve A which opens to the suction and delivery on its two sides, for the crossed ports of the steam cylinder, and for the slotted link, all for the purpose described.—No. 5584. April 16th, 1887. 8*d*.

Spinning Machinery.—*H. Stevenson, J. Webb, & S. Hallam, Manchester.*—These improvements relate to former patents granted to the same inventors, viz., Nos. 13440 of 1885, 4995 of 1886, and 3484 of 1887. In the apparatus described in these former patents, a hollow revolving spindle was employed, with a spinning device placed centrally above the tube, and with a wire hook placed centrally at the bottom of the tube. The present improvements consist in placing a flier below the hollow revolving tube and secured to it. The yarn is taken down the hollow tube, doubled over the leg of the flier, and led to a traveller. The effect of the flier is to assist materially in driving the traveller, thus tending to diminish and equalise the strain on the yarn as it is wound upon the bobbin. Three claims are made for the application of the flier on the bottom of the revolving spindle, in conjunction with the traveller, as described.—No. 6904. May 11th, 1887. 8*d*.

Yarn Taping Machines.—*J. Sugden & H. Colburn, Keighley, Yorkshire.*—The object of this invention is to deliver the threads from the beaming rollers to the loom warp beam at a uniform tension. A series of beaming rollers, having a gudgeon at each end, are mounted in a frame, and the gudgeons project into vertical slots; the roll of thread on each beam rests on a revolving driving drum, which causes the beam to rotate by frictional contact. The loom warp beam is driven in the usual manner, and the driving drums are caused to revolve by a shaft and gearing connected to the winding head of the machine. The gearing is so arranged that the circumference of the roll of warp on the loom warp beam travels slightly faster than that of the roll on the beaming rollers. Three claims are made.—No. 6526. May 4th, 1887. 8*d*.

ELECTRICITY.

DYNAMOS.—*A. J. Gravier, Paris.*—In order to increase the efficiency and economy of a dynamo, the armature is placed within a field whose magnets are either not opposed to each other, or if opposed in position, are, by reason of their unsymmetrical form, caused to act and re-act in a new manner. This arrangement is applicable to various constructions of dynamos. In applying it to the Gramme machine, the extension of one pole is made to the right, reaching nearly round to the opposite pole, and the extension of the other pole is made to the left in a similar manner. Also the armature is made to carry an amount of wire equal to that of the field magnets, in order to increase the e.m.f. Nearly the whole of the armature wire is used to the profit of the induction; it follows that the neutral field is reduced almost to a point. The same results are obtained in machines of the Siemens type by coiling the upper right hand bar and the lower left hand bar of the field. Three claims are made.—No. 5709. April 19th, 1887. 8*d.*

TANNING BY ELECTRICITY.—*E. Worms & J. Balé, Paris.*—The current of electricity sent through the contents of the tanning vessels has been found to accelerate the process of tanning. The vessel used in the apparatus here described consists of a rotating drum, upon the circumference of which are fixed two metallic rings electrically connected with circular conductors in the interior of the drum. By means of two spring rubbers connected to the two poles of a battery, and bearing against the external rings of the drum, an electric current is caused to pass through the contents of the drum during its rotation. Two claims are made for the construction of the drums with the rings for the purpose described.—No. 9515. July 5th, 1887. 8*d.*

DISTRIBUTION OF ELECTRICITY.—*W. Maxwell, London.*—This invention relates to a system of generating and distributing electricity in which continuous currents are employed. The continuous current is transmitted from the dynamos to the distributing centres, where a set of transformers change the current and its electromotive force. In conjunction with the transformers, secondary batteries are used to store either the primary or the secondary currents. When there are a number of distributing centres connected to one generating station, they may be connected together, so that no inconvenience shall be entailed by a temporary breakdown. The inventor makes two claims for the combination of reproducing transformers with storage batteries, as described.—No. 5562. April 16th, 1887. 6*d.*

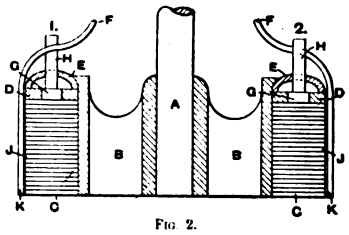
ELECTRICAL CONTROLLING APPARATUS.—*A. Siemens, London, and E. F. H. H. Lauckert, Charlton, Kent.*—The electric lamps being in the main circuit of the dyamo and the field magnets in a shunt circuit, the current is regulated by introducing a resistance into the latter circuit varying with the number of lamps in use. The main current is led through the coil of a regulating solenoid which has a movable equipoised core. The core moves in obedience to the attraction of the solenoid, and consequently makes one or other of two sets of contacts, according to its direction of motion; a small electromotor is brought into circuit by this means, and a greater or less number of resistances are introduced into the shunt circuit of the field magnets; the current in the main circuit is thus kept constant. The accompanying drawing illustrates diagrammatically an arrangement suited to supply a number of arc lamps Z. The main dynamo is at D; to the terminals T T¹ is attached a shunt circuit, which includes the field magnet coils of a small electromotor M. The worm W gears with a wheel which carries an arm S moving over

contacts for a number of resistances R. The regulating solenoid B has a core P linked to one end of the beam F, and a counterpoise C P is fixed to the other end. The arm G projects down from F, and is linked to a vertical arm L of a rocking shaft E, from which four wires project into the mercury cups $C^1C^2C^3C^4$. The current from T passes through the lamps and the coil of the solenoid B and back to T^1. When the current increases, the core P is drawn down and cants the beam F and shaft E, thus causing the wires to be immersed in the cups C^3C^4. A current from T is thus passed through C^3 to I, and from I^1 through C^4 and T^1, causing the worm W to revolve and drive the wheel in one direction, so that its arm S introduces an increased number of resistances R into the field magnet circuit until the current is brought back to its usual strength. When, on the other hand, the current from the dynamo decreases, the core P is raised and the shaft E is canted so as to immerse the wires in C^1C^2. A current from T then passes through C^1 to I^1, and from I through C^2 to T^1, causing the worm W to revolve in the opposite direction, and the arm S to move so as to lessen the number of resistances R in the field magnet circuit. Four claims are made.—No. 5637. April 18th, 1887. 8*d.*

GALVANOMETERS.—*P. Jolin, Bristol.*—The inventor attaches the magnet of a Thomson's syphon recorder directly to a rigid horizontal or vertical plate, which also carries the central core. This core is preferably formed of a compound magnet, in order to strengthen the field. The lower suspension is carried by a spring attached to the same plate, and the suspension is lengthened when in the vertical form by drilling a hole through the neutral part of the magnet, and allowing the suspension to pass through it to the spring; the electric connection is in that case made from this plate through the spring and lower suspension to the coil. In order to allow an adjustment for the coil the top suspension is attached to another plate, or to a tube with a suitable metal head capable of a rotary motion in a horizontal plane. The head is provided with another adjustment to raise or lower the coil; the top plate forms the other connection through the metal head and top suspension of the coil. The two plates, or the plate and tube, are attached to a piece of hard wood, which is provided with binding screws. The connection is made with mercury cups of a peculiar kind. The cup is of large size, and is well amalgamated in the interior up to ½in. of the top; an inverted cone piece fits tightly into the top of the cup; the cone is small at the bottom, and tapers inside and out in order to be of uniform thickness, and has a large opening at the top like a funnel. The inside of the cone is lacquered and the outside is amalgamated. By this arrangement, when the instrument is tipped over, the mercury follows the amalgamated part into the top of the cup instead of falling out. The inventor makes twelve claims.—No. 4369. March 23rd, 1887. 8*d.*

DYNAMOS.—*W. H. Ravenshaw, Halifax, W. T. Goolden, & A. P. Trotter, London.*—In winding a drum armature the inventors cover the whole of the periphery with the wires wound thereon, and hold the wires in place by passing between the coils a series of projecting pieces attached to the ends of the armature. The whole of the periphery is thus used for the purpose of winding. In the accompanying drawings Fig. 1 is a sectional elevation of part of the commutator end of the armature, and Fig. 2 is a plan of the opposite end. The core C is formed of iron discs J; outside the discs is placed a disc of vulcanised fibre D, which is

FIG. 1.



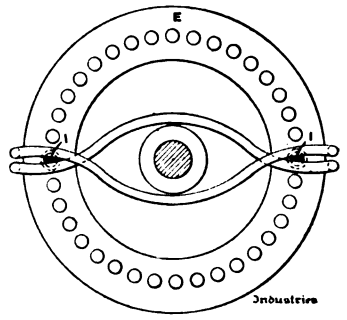


FIG. 2.

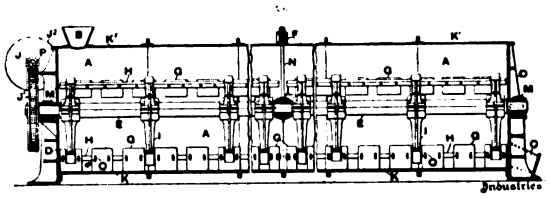
pierced to receive the heads G of the fibre pins or projecting pieces H. These pins are formed with flattened shanks, as shown in Fig. 2. An outer ring of cast iron E is secured to the armature, in order to retain these pieces in their places. The ring is pierced with holes, through which the shanks I of the fibre pins project. The wires K, after traversing the periphery of the armature in any desired manner of winding, have their ends F brought past the pins 1 2 to the commutator. In Fig. 2 a typical method of passing the wires round the pulley end is shown, the pins I in this case serving to retain the two adjacent wires in place. It is equally permissible to employ two or more sets of pins, as the particular method of winding may necessitate. The inventors claim the method of constructing the armature with end pins for the purpose of retaining the wires in their places.—No. 5303. April 12th, 1887. 8*d.*

CHEMISTRY.



CHLORATES OF THE ALKALIES.—*H. Gall & Viscount Amaury de Montlaur, Paris.*—The process described in this invention relates to the manufacture of the chlorates of the alkalies from the corresponding chlorides. The solution of the respective chloride is submitted to the action of an electric current in a trough which is provided with a porous partition. The trough may be of earthenware, and is divided into ten parts by a diaphragm, which may be composed of porous earthenware. To avoid the reducing action of the hydrogen which is separated at the negative pole, the liquid in the negative compartment is caused to circulate by exterior tubes towards the positive compartment, so that the base formed may combine with the chloric acid. Platinum and iron are employed for the positive and negative electrodes respectively. For separating the chlorate advantage is taken of their difference in solubilities in water. One claim is made.—No. 4686. March 29th, 1887. 6*d.*

TREATMENT OF PHOSPHATES.—*W. L. Wise, London. (E. Solvay, Brussels.)*—In order to prepare phosphates for use in agriculture, the inventor mixes the phosphate with silica or alumina in such quantities that the silica and alumina will be sufficient to take up all the bases, either free or united to the phosphoric acid. The mixture is heated along with fuel which is adapted to the particular phosphate in use. To the products thus obtained is added common salt or chloride of potassium, and the whole is calcined in the presence of air or steam. Chlorine or hydrochloric acid is set free, and the residuum contains a soluble phosphate of soda or potash. This phosphate, on being treated by lime, gives precipitated dibasic phosphate and a solution of caustic soda or potash. The apparatus employed in carrying out this process consists of a reverberating furnace, or of a revolving furnace used in the Leblanc process. One claim is made for the process for liberating the phosphoric acid from the phosphate of lime, as described.—No. 6632. May 5th, 1887. 6*d.*

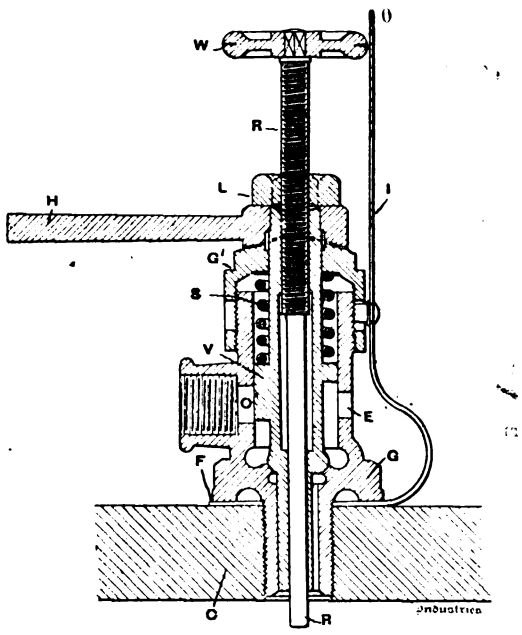
CAUSTIC SODA AND POTASH.—*A. Delhaye, Brussels.*—This process is based on the preparation of phosphate of soda either by decomposing sea salt with phosphoric acid, or by precipitating a concentrated solution of acid phosphate of calcium by sulphate of soda. The phosphated mineral is mixed with a sufficient quantity of hydrochloric acid to dissolve the whole of the phosphoric acid. The reaction having taken place, some sulphuric acid is added, and sulphate of lime is precipitated. Common salt is then added, and the acid phosphate of sodium is produced. If sulphate of soda is employed the mineral is mixed with a certain quantity of sulphuric acid; the mass is stirred until the reaction ceases, and sulphate of soda is then added. Sulphate of lime and acid phosphate of soda are thus produced. The acid phosphate so obtained is employed in the manufacture of soda, after the addition of a proportion of carbonate of soda. Four claims are made for these two processes.—No. 4371. March 23rd, 1887. 6*d.*

SACCHARINE.—*A. G. Salamon, London.*—The object of this invention is to prepare a soluble powder of saccharine without the usual quantity of alkali. The amounts made use of in this preparation are: Saccharine 25lb., bicarbonate of soda 10lb. 3oz., and a suitable proportion of water. The mixture is evaporated, and the resulting product weighs 28lb. 3oz. The powder thus obtained contains 90 per cent. of saccharine, and is soluble in 20 per cent. of its weight in cold water. The inventor makes one claim for this process.—No. 13839. October 12th, 1887. 6*d.*

MANUFACTURE OF CAUSTIC ASH.—*T. T. Mathieson & J. Hawliczek, Liverpool.*—According to the present invention, caustic ash is manufactured from a mixture of monocarbonate and bicarbonate of soda by the injection of a spray of strong caustic liquor while the soda is being continually agitated. One form of apparatus designed for carrying out this process is illustrated in longitudinal section in the diagram. The lower half K of the vessel A is made of cast iron, and the upper half K^1 of wrought iron or steel. The upper half is of light construction and serves chiefly as a covering, while the bottom part is placed above a furnace, and also bears the greater proportion of internal wear, owing to the action of the agitated material. B represents the hopper which allows the introduction of the carbonates, and C the shoot through which the ultimate product makes its exit. The ends D are made in halves, and carry the bearings M for the main shaft E; the suspended bearing L is placed midway between the ends, and is held in position by the rods N. The blades or scrapers G are secured to bars H, which are of rectangular cross section, and are carried by the arms I mounted on the shaft E. The ends of these arms are provided with caps, which are bolted to the arms, gripping the bars H between themselves and the main portion of the arm. J represents a worm, and J^1 a worm wheel mounted on the end of E; this gear serves to drive the shaft and scrapers. The caustic liquor is supplied in the form of a spray through special perforations in the side of the case. It is so arranged that the bicarbonate shall have been converted by the scrapers into monocarbonate

before the sprays reach it, on account of the fact that the liquor affects the monocarbonate more readily. The interior of the chamber may be kept free from scale by providing every alternate blade with an auxiliary scraper. The case is preferably 30ft. long, and the shaft performs three or four revolutions per minute, and the material will be propelled from one end to the other in three-quarters of an hour. Five claims are made for the process, and for this and another form of apparatus.—No. 5757. April 20th, 1887. 11*d.*

MISCELLANEOUS.



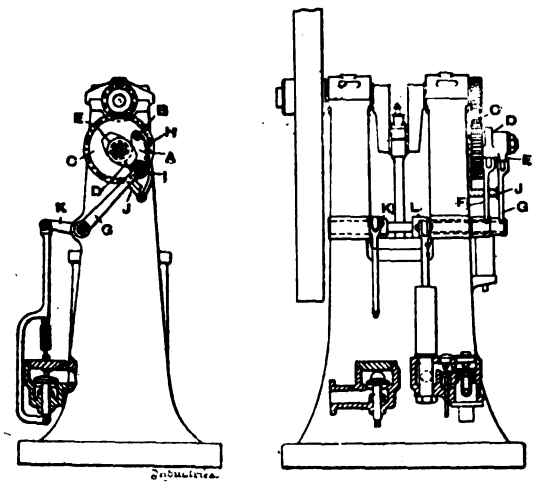
TREADLE MECHANISM.—*P. L. Gerisher & F. W. M. Schröder, Leipzig.*—In the improved mechanism there is a crank, one of whose arms moves in a slot radially arranged in the fly wheel, while the shorter arm is connected by a rod with the treadle. The shorter arm of the crank is turned by foot pressure, and the motion is transmitted to the longer arm, which moves the fly wheel. The crank shaft is so arranged with regard to the main shaft that the longer crank arm acts eccentrically on the fly wheel. The longer arm is so arranged that the lever length with which the fly wheel is moved is the greatest when the poise of the fly wheel acts with its gravity against the revolution of the fly wheel; and its lever length is smallest when the poise has arrived at its opposite position, in which case it contributes to the revolution of the wheel. Therefore the lever length with which the fly wheel is moved is increased with each revolution in the same proportion in which the action of the poise against the revolution of the fly wheel increases, and is decreased again in the same proportion in which the action of the poise for the revolution of the wheel increases. In this way, it is claimed that the utilisation of force of each revolution is more uniformly distributed, and a more uniform motion of the fly wheel is obtained. One claim is made.—No. 6512. May 3rd, 1887. 8*d.*

MANUFACTURE OF PAPER PULP.—*A. Wilkinson, Chiswick, Middlesex.*—One hundredweight of vegetable fibre is submerged in a tank containing 250 gallons of hot water, to which is added about 5lb. of chloride of lime and 3lb. of sulphuric or hydrochloric acid. After this solution has stood for twelve hours, the gummy matter contained in the fibre will be loosened. On the completion of this process, the fibre is removed to an ordinary close boiler, and there boiled to any suitable pressure depending on the nature of the fibre under treatment. The fibres are afterwards boiled in a vessel containing spent chlorine liquid. For this purpose 250 gallons of chlorine liquid is placed in a close boiler, with about 80lb. of crystalline soda and 14lb. of hydrochloric or sulphuric acid. This mass is allowed to remain at a temperature of 75°F until the solution is complete. The

Digitized by Google

fibre is then boiled in this liquid to any suitable pressure for six or eight hours; the liquid is afterwards drawn off and placed in tanks for the next batch of fibre to be treated. The fibre is washed in hot water and boiled in another similar solution of chlorine liquid. The next operation to which the fibre is submitted is the washing in 500 gallons of water in which is contained 28lb. of acid. After this treatment the fibre is ready for bleaching. For this purpose 1cwt. of the fibre, 7lb. of sulphide of barium, and 7lb. of acid are mixed in a tank and allowed to remain for six hours, after which time the fibre is transferred to a solution of 4lb. of bisulphide of lime or magnesia and 1lb. of sodium hypochlorite in 500 gallons of cold water. In weighing the pulp before it is run on to the rollers of the paper machine, a pulp of rice, animal size, and baryta is mixed with the fibre, and a little starch and borax may be added to produce a glaze upon the surface of the paper while passing between the rollers. One claim is made.—No. 3937. March 15th, 1887. 6*d*.

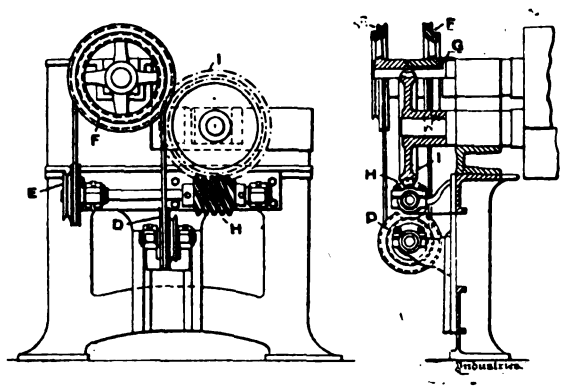
Safety Apparatus for Steam Cylinders.—*J. S. Warburton and H. J. Sanderson, London.*—In order to reduce the clearance in the cylinder to a minimum without entailing any danger, the inventors place relief valves at both ends of the cylinder. A spindle projects from the valve into the cylinder, and as long as the piston pursues its right path it does not come in contact with it; but directly the spindle is pressed the valve is operated as afterwards described. The figure represents a longitudinal section of the apparatus. The valve box G is furnished at its lower end with a screw thread for fixing it to the cylinder. The orifice E allows the steam to escape when the alarm is given, and the orifice O is brought into operation when the apparatus is used as a drain cock or relief valve. The valve V is held to its seat by the spring S, whose reverse end presses against the inside of the gland G¹. The rod R passes through the centre of the relief valve, and is surmounted by an index wheel W. The



check nut L locks the rod R after having adjustment, and prevents the emission of steam beyond the end of the relief valve. The index plate I carries a scale on which can be read the distance between the end of the rod R and the cylinder cover. The handle H is provided with an inclined boss, which rests upon the gland G¹. This gland is also provided with a corresponding scroll, so that when the handle is turned the valve will be raised from its seat to allow a free passage for the steam, either to the drain orifice O or to the alarm orifice E, according to the direction in which the handle is turned. When the handle is in the central position the relief valve V remains upon its seat, and all communication is stopped until the valve is raised by pressure at the end of the rod R. The rod R may be raised either by the piston or by the too great pressure of the steam. Five claims are made for the combination of valve V, rod R, and handle H, as described.—No. 5585. April 16th, 1887. 8*d*.

Elevating Band Chains.—*J. Qualter & E. Hall, Barnsley.*—The usual picking bands and elevating band chains have hitherto been made from expensive forgings or malleable castings. The present inventors use a section of L shaped iron, rolled expressly for the purpose, and cut into lengths to form links. These links are riveted together at suitable centres, so as to pass over flat sided drums. A semi-circular piece is taken out of each end of the links; at the upper side of each link a steel plate is secured, which is riveted to the flange of the link. The inventors do not limit themselves to this particular form, but claim the construction of the improved band made from specially rolled iron or steel for the purpose described.—No. 6374. May 2nd, 1887. 6*d*.

Decorating Tin Plates.—*F. H. Rees, London.*—In the ordinary transfer system of decorating and printing on tin plates, the impression is often spoilt by the removal of the paper. In order to obviate this and other disadvantages, the inventor takes a piece of mill board and renders it water proof by rubbing it over with hydrocarbon oil. A covering of varnished cloth or oil baize is attached to the board; the surface of this material is made perfectly level and smooth, and is rubbed over with hydrocarbon oil and turpentine. The required design is made in the usual manner upon the stone, wood, or metal plate. An inked impression of the design is made on the prepared board, and from thence transferred to the tin plate. In practice the two sides of the board are used alternately, so as to save time and expense. One claim is made for the process of transferring the printed design by means of the prepared board.—No. 14321. October 21st, 1887. 4*d*.



GERMAN PATENT ABSTRACTS.

Gas Engines.—*C. Pieper, Berlin.*—This invention relates to the valve gear and regulation of gas engines. The igniting apparatus and the exhaust valve are actuated by the catches D and E and the levers F, G, K, and L. The catches D and E are

revolved by a cog wheel C, which is fitted with a weight A. If the speed of the engine exceeds a given limit, the weight A is moved towards the circumference of C, actuating the lever I in such a manner that the catch J engages with the lever G, thereby influencing the exhaust valve and retarding the speed of the machine.—No. 42600. August 31st, 1887.

Rolling Mills.—*P. Tafel, Augsburg.*—The motion of the roller actuated by the power is transmitted to the other roller by means of a rope and a worm H and worm wheel I. The endless rope is conducted over a pulley C keyed to the roller

shaft, then over an adjustable pulley D to a loose pulley F on the same shaft as C. From F it goes round a pulley E keyed on to the shaft of the worm H, and then back over C. In order to alter the relative speed of the two rollers, the pulleys are cone pulleys, and the tension of the rope is adjusted by moving the pulley D up or down.—No. 42354. March 31st, 1887.

UNITED STATES PATENT ABSTRACTS.

Steam Engine.—*J. D. Bowne, Jamesburg, New Jersey.*—The cylinder oscillates in horizontal bearings, and is supported on two trunnions fixed to the middle of its length. One of the trunnions is bored out so as to form the sides of the steam chest. The steam pipe passes through a circular stuffing box, and the steam arrives on the face of a stationary side valve. The oscillating motion of the cylinder over the face of this valve brings the two steam ports and the exhaust port into register with openings in the valve at the right time. The inventor makes three claims for this method of supplying the cylinder with steam.—No. 379630, dated 20th March, 1888.

Propelling Water in Pipes.—*T. H. Bolmer, New York.*—The apparatus here designed for the purpose of setting up a current of liquid consists of a chamber which forms an enlargement of the pipe. The water enters the chamber through a valve which opens in the direction of the flow, and another valve at the point where the water leaves the vessel opens in the same direction. Two gas chambers containing air and hydrogen respectively are connected by means of pipes to the upper part of the large vessel, and their contents fill it partially with the explosive mixture. When sufficient water has entered the chamber an explosion is caused which drives the water through the valve in the exit pipe. The repetition of this process generates a constant flow of the water. Two claims are made.—No. 379674, dated 20th March, 1888.

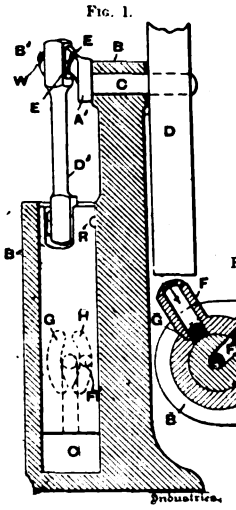
Corn Planting Attachment for Ploughs.—*F. L. Aten, Round Rock, Texas.*—This attachment may be combined with a plough of any construction, and is supported by a downwardly projecting bracket secured to the inner side of the rear end of the beam. A box or flanged way is fixed upon the side of the bracket, and a standard slides in it. A seed box is carried at the upper end of the standard, and is provided with a longitudinal groove in its upper side, and with slots in the end walls registering with the groove. An arm projects laterally from the lower end of the standard, and carries a wheel; a system of levers transmits the rotary motion of the wheel to the rear end of the seed slide, and so causes the grain to be deposited in the ground at intervals. Two claims are made.—No. 379554, dated 20th March, 1887.

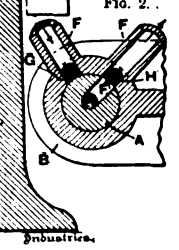
Filtering Plug.—*W. H. Macdonald, Washington.*—This invention is intended to be inserted in ordinary house water taps. The plug is of the usual shape, but is made hollow for the reception of some coarse filtering material such as charcoal. The openings in the side for the passage of the water are covered with fine wire gauze in order to confine the charcoal. A handle at the top screws on a short thread on the upper end of the plug, so that the plug can be turned round in one direction; when turned in the contrary direction the handle screws off, and exposes a hole in the plug through which the filtering material is inserted. In order to prevent the screw jambing, two notches are made in the handle, which fit in corresponding notches below the screw thread on the plug. Four claims are made.—No. 379801, dated 20th March, 1888.

Steel Springs.—*E. W. Gillon, Brooklyn.*—In forming steel springs from Bessemer steel wire, the wire is first hard drawn, and then bent into the requisite shape. The hot metal is immersed in an oil bath, and afterwards in a bath of molten metal. The spring thus formed is finally cooled by being plunged into a common tempering bath. Two claims are made for this process, as described.—No. 379573, dated 20th March, 1888.

Valve Gear.—*L. H. Nash, Brooklyn.*—This invention is a device for making the piston act as its own inlet and exhaust valve. The piston A works in the cylinder C, and the connecting rod D¹ imparts rotary motion to the shaft C¹. A port F¹ is formed in the side of the piston, and leads to its lower end. The two

Fig. 1.





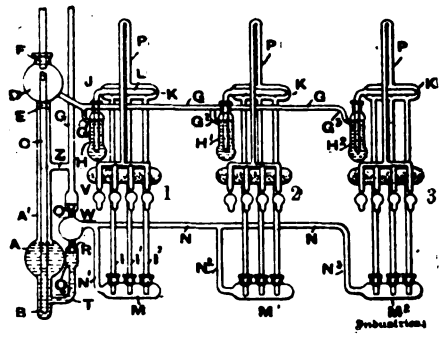


Fig. 2.

ports G H in the side of the cylinder act as the steam and exhaust ports respectively. The crank pin is inclined to the axis of the shaft C¹, and the bearing parts E at each end of the connecting rod have cylindrical interior and exterior bearings arranged at right angles to each other. The piston A thus receives an oscillating motion round its cylindrical axis, and acts as its own slide valve. Five claims are made.—No. 378847, dated 28th February, 1888.

Air Pump.—*H. J. Doerr, Newark, New Jersey.*—The arrangement of this mercury air pump will be understood by reference to the diagram. The mercury reservoir is shown at A; the

tube A¹ is closed at its upper extremity; and the suction pipe C extends between the upper reservoir D and the lower reservoir A. The tube Y is connected with the tube A¹ through the tubes T and Z; and two valves W and R regulate the entry of the air and mercury into the bulb O. The bulb O is in communication with two series of chambers M M¹ through the pipes N N¹, and the bulb D is connected with the vessels K K¹ by means of the tubes G J. The fall tubes are shown at I, and the exhaust tubes at P. Two claims are made for this air extractor.—No. 378666, dated 28th February, 1888.

The full specifications of the British and United States patents, and the Official Journals of the German Patent Office, from which the above abstracts have been compiled, and the Official Journal of the United States Patent Office, may be seen by subscribers and clients at the Reading Room, Manchester Office of Industries, *where also Patent Indexes from* A.D. 1617 *may be consulted. Copies of the British specifications may be obtained on application to* H. Reader Lack, Esq., *Comptroller-General, Patent Office, Southampton Buildings, London, W.C. The published price must be remitted, together with a sum sufficient to cover postage, which may be reckoned at ½d. for every 10d. or fraction of 10d. Remittances exceeding one shilling must be made by Post Office Order.*

IMPROVED STEAM SANDING APPARATUS.

ARRANGEMENTS to prevent locomotive wheels from slipping have hitherto not received that attention which their practical importance deserved. This fact is the more surprising, when we consider how greatly the economic working of the locomotive is affected by the slipping of the driving wheels. The apparatus we illustrate herewith has been devised to meet this want, and is manufactured by Messrs. Gresham & Craven, engineers, Salford. As will be seen, it is extremely simple in construction, and a great improvement upon the old fashioned system of sand box and pipe. Referring to our illustrations, Fig. 1 shows a side elevation of a locomotive fitted with the complete apparatus, and Figs. 2, 3, and 4, vertical sections of the details. It will be seen from Fig. 1 that the arrangement consists essentially of three parts: The steam valve A for supplying and regulating the steam to the ejector, a sand trap B which can be fitted on existing sand boxes, and the small ejector C, which lifts the sand, and impels it under the wheel at the line of tread. In this apparatus it has been found desirable that the steam should be perfectly dry, and an ingenious method of accomplishing this end may be seen in the steam valve section (Fig. 2); the condensed steam which accumulates being allowed to escape through ports in the plug, and conducted away by a drip pipe. The method of working this system is as follows: The driver, by means of the valve A, admits steam to the ejector, as shown by the horizontal arrow in Fig. 4. As indicated by the arrows, the air is thereby drawn in through the hole in the cap of the sand trap. It then strikes on the sand, which is scoured on the surface, and carried down until it comes in contact with the steam jet. It then mixes with the steam, and is driven under the wheel. The makers claim the following advantages for this system: The use of coupling rods may be dispensed with, as a single engine fitted with this apparatus has as much adhesion as a coupled engine without it; great saving of sand, as the apparatus is able to deliver in large or small quantities; absolute certainty of delivering at the position required, irrespective of wind; simultaneous delivery to both wheels, thus minimising the liability to injure or strain the driving axles; and no rods or levers are required for working the gear. No additional train resistance is caused, as no superfluous sand is left on the rail, and by the prevention of slipping some economy in fuel is effected. We understand that the apparatus is being used on nearly every important railway in the kingdom, including the Midland, Great Northern, and the Manchester, Sheffield, and Lincolnshire lines, and has given complete satisfaction.

(Concluded from page 366.)

THE next paper read was by Mr. W. C. Wallace, on

THE MATERIAL BEST SUITED FOR PROPELLER BLADES.

In this paper the author presented data regarding the strength, durability, and cost of propeller blades made from various materials. These materials were the following: Cast iron, steel, gun metal, manganese bronze, phosphor bronze, delta metal, and aluminium bronze.

Until recent years cast iron was the material most generally in use for propeller blades, and is still in favour with some engineers. Its most serious defect is its liability to fracture, and the increase in thickness of the blade necessitated thereby. It is not to be recommended where trustworthiness is a desideratum, but has the advantage of being cheap, of preserving the true form of the screw in casting, and of having a smooth surface. Cast iron propeller blades require to be renewed every five or six years. The cost of finished blades may be taken as from £20 to £24 per ton.

The introduction of mild steel as a material for propeller blades has been a great improvement, rendering them absolutely trustworthy as regards strength, but bringing about the evil of corrosion. The blades become so pitted and broken in a few years that they have to be renewed, and with steel it is not possible, as with cast iron, to burn on new tips. The life of steel blades varies from three to six years. Many attempts have been made to protect steel blades from becoming pitted by a covering of some other metal. Mr. Johnstone applied tin to the back of the blades near the tip, and other inventors have applied brass plates to cover that portion of the back of the blades which is most subject to corrosion. It is, however, extremely difficult to prevent water from getting behind the coating, and thus setting up galvanic action. The present price for finished steel blades is from £35 to £40 per ton.

Gun metal has been used almost as early as cast iron, but the use was restricted to the Royal Navy and to small private vessels. It has great resistance to corrosion, the life of the blades being in most cases longer than that of the ship; but owing to the galvanic action between the blades on the hull, serious pitting would take place in the stern frames and plating if the latter were not protected by placing strips of zinc round the inside of the propeller aperture. The zinc is consumed, but the hull is preserved. The quantity of zinc required for a propeller of 20ft. diam. is about 3cwt., and must be renewed every twelve or fifteen months at a cost of about £10. In point of strength gun metal is only slightly ahead of cast iron, but it is not so brittle. The present price for finished blades is about £130 per ton.

Manganese bronze, like gun metal, is free from corrosion, but is difficult to cast, and sets up galvanic action, requiring the application of zinc, as already explained. Its price is about £5 higher than that of gun metal.

Phosphor bronze has an ultimate tensile strength of 15·8 tons, and in this respect is not much superior to either gun metal or manganese bronze; but its elongation is 17½ per cent., showing its great ductility. No large propellers have, so far as the author is aware, been made of this metal; but in steam launches and torpedo boats it has been used. The price of finished blades is £170 per ton.

Delta metal, which is an alloy of copper, zinc, and iron, and which has a breaking strength of from 15 to 23 tons, with an elongation of from 10 to 20 per cent., has to a limited extent been used for the propellers of sea-going ships; but the author was unable to speak either of its trustworthiness or of its lasting qualities. The price for finished blades was given as £115 a ton, or five times that of cast iron, and three times that of steel.

Aluminium bronze has up to the present been little used for propellers of any size; but if aluminium brass is all that the advocates of this material claim for it, the author considers it likely that it will be largely used for propellers. The following table gives some data as to the strength and elongation of some aluminium alloys manufactured by the Cowles Company:—

Bronze composition.	Elongation per cent.	Tensile strength. Tons per sq. in.
Copper and 8% aluminium and silicon.....	23·7	26·1
" 10 " "	3·2	30·4
" 8½ " "	26·0	27·2
Brass composition.		
Copper, 3½ aluminium and 33½ zinc	1·6	31·3
" " "	2·5	36·8

An 8½ per cent. aluminium bronze is recommended by one of the officials of the United States Navy for twin screws, but the high price of £235 per ton for finished blades renders its adoption in the merchant navy almost impossible. The following table contains a summary of the strength and elongation of the various materials above enumerated:—

	Ultimate tensile strength. Tons per sq. in.	Elongation. Per cent.	Weight to break bar 1in. by 1in., 12in. between supports. Cwt.
Cast iron	10	—	18
Steel	31	10	55
Gun metal	14	9	23
Manganese bronze.....	15	—	28
Manganese bronze (by Bronze and Brass Co.)	—	—	45
Phosphor bronze (by Phosphor Bronze Co.).....	16	17	24
Delta metal.....	19	15	—
Aluminium brass	34	2	—

Digitized by Google

Practical experience has led to steel blades being made 25 per cent. thinner at the root than cast iron, whilst for manganese bronze and aluminium brass an allowance of 30 per cent. may be assumed. Delta metal may be allowed 25 per cent. reduction, and gun metal and phosphor bronze each a reduction of 10 per cent. Making these allowances, the relative cost of blades compared with cast iron is as follows:—

	Cost per ton.	Equivalent cost of blades for every ton of cast iron blades.
	£	£
Cast iron	24	24
Steel	38	33
Gun metal	130	144
Manganese bronze	135	123
Phosphor bronze	170	153
Delta metal	115	110
Aluminium bronze	145	139

The relative first cost is, however, not the only item of expenditure which must be considered. Shipowners must remember that the renewal of blades and the difference in power consumed are also important matters. Assuming cast iron blades to last six years and steel blades four years, then for a vessel of 5000 tons, having four propeller blades of joint weight 12 tons, if of cast iron, an expenditure of £288 every six years, and if of steel an expenditure of £396 every four years, would have to be incurred. The saving in the cost of cast iron would allow of three out of the four blades being replaced every four years, after failure due to accidents of such a nature as would leave steel intact. Comparing steel with the other metals in the table, the author pointed out that with steel the coal bill would be larger and the renewals more frequent. The power required with a propeller of manganese bronze is 4 per cent. lower than that with a steel propeller of the same shape and doing the same work, and in the case of a 5000-ton ship, consuming 50 tons of coal a day, the saving would be £2 daily, representing an annual charge against steel blades of £300, taking one hundred and fifty as the number of days at sea. In four years the amount becomes £1,200, which, added to the £396 given above as the price of steel blades, makes £1,596 as the disbursement in connection with steel blades for four years; whereas with gun metal blades the total cost of the propeller would be £1,728, and this expenditure would be equivalent to that of a steel propeller if the gun metal propeller had to be renewed every 4⅓ years.

The discussion was opened by Admiral Colomb, who asked for information as to the cause of corrosion of steel blades. It seemed to him remarkable that the corrosion should take place at the back of the blades, and that the grooving should be radial instead of circumferential.

Mr. Hall, although speaking as a steel manufacturer, could not deny that as regards corrosion, steel is far worse than cast iron. The speaker advanced a very extraordinary theory as to the cause of corrosion. Some four years ago, he had to examine an old steel boiler, in which the rivets were of wrought iron, and he found that the material surrounding the rivets had deteriorated. This he explained by a transfer of carbon from the steel plate to the wrought iron rivet, which, as he termed it, sucked away the carbon out of the boiler shell. Similarly he thought that a wrought iron stern post may suck the carbon out of the steel propeller blade, and as a remedy he proposed to make the stern post also of steel. In his opinion corrosion is aided by the vacuum behind the blade causing the water to surge. On the whole he considered the use of mild steel for propellers a mistake, and anticipated a great future for some suitable steel alloy.

Mr. Martell, referring to Admiral Colomb's question, remarked that the inventor of some antidote to corrosion would certainly secure a big fortune. At present the only plausible theory in explanation of corrosion is, that the front of the blade meets with a solid body of water, but that air penetrates to the back of the blade, and so produces scouring. The speaker agreed with Mr. Hall's condemnation of mild steel, and remarked that the most tenacious and therefore the softest iron becomes more pitted than hard iron. He was surprised to see that "mitis" metal had been completely omitted from the list given in Mr. Wallace's paper, and he believed that there is a great future for this material in connection with propellers.

Mr. Manuel said he had devoted considerable attention to the question as to the best material for propeller blades since the year 1880, the immediate reason for discarding cast iron being the frequent cases of breakage when the blades strike an obstacle, and the blunting of the edges, which increases the resistance. He had had some steel blades made by Messrs. Vickers, of Sheffield, which were found to possess the very desirable quality of not breaking when striking an obstacle, but of simply bending. On the other hand, the corrosion at the forward part was much greater than with cast iron. To remedy this evil he applied brass sheathing let in flush with the surface, and this lasted in some cases for six or seven years, but in others only for two or three years. He had recently improved the brass sheathing by shaping it like a ploughshare, so as to keep a fair cutting edge. As regards manganese bronze, he had long hesitated to adopt it, owing to the many cases of breakage of the blades in the Atlantic, which sometimes were simply due to the racing of the engine. In discussing the matter with Mr. Parsons, the maker of manganese bronze, he learned that these failures occurred to propellers which were made by other manufacturers, but that his own had never broken, and the speaker therefore fitted one of his company's steamers with a manganese bronze propeller, and on the next voyage to Australia the average speed of 12·35 knots was made instead of 12·11 knots as on previous voyages. To further test the relative value of manganese bronze, he had recently fitted two sister ships, the "Britannia" and the "Victoria," one with steel and the other with manganese bronze blades. On the measured miles the results were as follow:—

	Revolutions of engine.	Steam pressure.	Speed.	Slip, per cent.
"Victoria," with manganese bronze blades	63	146	16·52	8
"Britannia," with steel blades	64·64	146	16·47	10

The speaker thought that the superiority of manganese bronze was not so much due to the smaller thickness of the blades as to the sharper cutting edge.

Mr. Fothergill, referring to the possibility of a ductile blade bending instead of breaking, considered that this is not altogether an advantage, as especially in four-bladed screws the speed of the vessel may be seriously retarded, and power may be wasted, by one of the blades being bent; whereas, if the blade were entirely lost through breakage, the efficiency would be almost the same, whilst the speed would be only slightly diminished.

The last paper read was by Mr. J. H. Heck, on

The Influence of Size and Speed on Collisions at Sea.

The author drew attention to the vague character of the existing regulations as regards reduction of speed in foggy weather, and the omission of the element of size, which is of some importance. It is quite possible for a small vessel, when going at full speed, to be more under control than a large steamer going at half speed. By theoretical investigations, which the author gave in an appendix, he arrived at the following results:—

(1) Two steamers of different maximum speeds, but of equal size and displacement, when going at full speed, can be stopped in the same distance by the reversing of the engines. Showing in vessels of equal dimensions and form, but of different maximum speeds, that in foggy weather the faster vessel can go at a greater speed, and still be under the same control as the slow vessel.

(2) If two vesssels of different maximum speeds, but of equal size and displacement, are going at equal speeds, the fast vessel would be under greater control, and could be stopped in a lesser distance, by the reversing of the engines.

(3) A vessel when in the light condition is under much greater control than when loaded, and can be stopped in a shorter distance by the reversing of the engines. In thick or foggy weather, therefore, a loaded vessel should go at a less speed than when simply making a voyage in ballast.

(4) Of two steamers of the same form and speed, but one having twice the dimensions of the other, the smaller vessel is more under control, and can be stopped in half the distance; in other words, the larger vessel would go through twice the distance after the engines were reversed before she would come to rest. From this it follows that if the condition of the weather renders a reduction of speed prudent, then the reduction of speed should be greatest in the case of larger vessels.

(5) Of two vessels of the same size and form, but having different maximum speeds, while both can be stopped in the same distance by the reversing of the engines, the faster vessel will come to rest in less time than the slow one. The loss, of course, of a few seconds by a captain or mate being undecided what to do would be of more consequence in the case of a fast than a slow vessel.

(6) Of two vessels of similar form and speed, but of different dimensions, the smaller vessel will come to rest in less time than the larger; more promptness is, therefore, necessary in the case of the larger vessel.

(7) Steamers travelling between ordinary speeds will go an enormous distance before coming to rest if the engines are simply stopped but not reversed, this distance being at least from twenty to thirty lengths, according to the speed and size of the vessels, showing how much less under control a sailing vessel is when compared with a steamer.

In conclusion the author advocated that experiments on retardation and steering qualities of vessels should be made during the course of the ordinary speed trial trips, to enable seamen to get more reliable and accurate information in regard to the vessels under their charge.

COMPRESSED OIL GAS AND ITS APPLICATIONS.

At the ordinary meeting of the Institution of Civil Engineers, held on the 10th inst., a paper was read on the above subject by Mr. Arthur Ayres, M.Inst.C.E. In considering this system of illumination, its applicability to buoys, isolated beacons, lighthouses, and railway carriages, &c., the author treated it under the primary heads of mode of manufacture, illuminating properties, cost, storage, and transit, and in doing so he referred to the early history of oil gas, and the patents taken out from time to time in connection with the system. In 1825 Faraday contributed a paper to the Royal Society "On New Compounds of Carbon and Hydrogen, and on certain other Products obtained during the Decomposition of Oil by Heat." That communication, however, dealt with the chemistry of oil gas. It was mentioned in that paper that 1000 cub. ft. of good gas yielded nearly one gallon of hydrocarbon. The gas from which the hydrocarbon was obtained was manufactured by the Portable Gas Company, and was compressed to 30 atmospheres. It was drawn from a gasholder and passed over water into a large and strong receiver, and from it into portable vessels, the principal condensation taking place in the receiver. The oil gas manufactured by the Portable Gas Company was not distilled from shale oil or petroleum, but from other oils and fatty substances, mineral or vegetable. Between the years 1792 and 1883, numerous ingenious patents were taken out for manufacturing and compressing oil gas for lighting and heating purposes. Oil or hydrocarbon gas was the product of heavy petroleum, or shale oil once distilled. It had a specific gravity of about ·840, and flashed at about 220°F. In detailing the process of the manufacture of oil gas, the author described the works erected at the South Foreland by Pintsch's Patent Lighting Company, Limited. The illuminating intensity of oil gas might be taken at from forty to fifty candles when burned in a London standard Argand burner, with a consumption of 5 cub. ft. per hour, under a pressure of 0·5in. of water. The price varied from about 5s. 6d. to 16s. per 1000 cub. ft., being directly influenced by the quantity of gas produced, the management of the retorts, and the price of oil, fuel, and wages. Until the adoption of oil gas for their illumination, buoys and isolated beacons were only useful for the purposes of navigation by day; but they were now equally so by night (in clear weather), enabling vessels to navigate with safety intricate channels, which hitherto could not have been attempted except at considerable risk. Gas buoys (see *Industries*, Vol. I., page 560), as at present used by the Honourable Corporation of Trinity House, were constructed of best mild steel; they were spherical, 9ft. in diameter, and surmounted by a light wrought iron superstructure, carrying a lantern enclosing the illuminating apparatus. The total weight of one of these buoys complete was about 80cwt., the weight of the buoy being 78¾cwt., and that of the illuminating apparatus 1¼cwt. The buoys were usually charged to a pressure of 5 or 6 atmospheres, or from 75lb. to 90lb. pressure per square inch. The gas was contained in the spherical portion of the buoy, the capacity of which was about 382 cub. ft., and was consumed at the rate of 0·75 cub. ft. per hour, burning night and day continuously. When fully charged to 5 atmospheres, and burning at the above rate of consumption, the light would be maintained for 106 nights and days. The intensity of the light was from 17 to 20 candles through the lens. The estimated cost of a first class gas buoy, including the lantern and illuminating apparatus, also royalty, was about £420. In a new form of gas buoy, constructed wholly of mild steel, it was intended to carry the gas in the lower portion of the buoy. The capacity for storage of gas would be 383 cub. ft., which, at a pressure of 5 atmospheres, would sustain the light (consuming 0·75 cub. ft. per hour) for 106 nights and days. The advantages of this form of buoy were improved stability and its applicability to the recently adopted uniform system of buoyage. The estimated weight of this buoy was about 6 tons, without moorings. In 1885 the Canadian Government adopted a combination of the bell and gas buoy for service in the Gulf of St. Lawrence; the bell, weighing 3cwt., giving the usual warning by day and night, supplemented by the light. The gas was stored in a welded cylinder (independent of the buoy proper) having a capacity of 339 cub. ft. The cylinder, when charged to 6 atmospheres, was capable of maintaining the light for 113 nights and days. The weight of the buoy complete was 9½ tons. In 1881, a beacon, lighted automatically by compressed oil gas on Pintsch's system, was adopted by the Clyde Trust Commissioners, who had recently erected another on the Gantock Rock, off Dunoon, on the Argyleshire coast, and who were extending this system of illumination at Cardross and Dumbuck lighthouses, Donald's Quay, Rashilee, and Dalmuir light towers. In December, 1885, two iron lighthouses, similar in construction, were erected by the Trinity House, one at Stoneness, opposite Greenhithe, and the other at Broadness, on the Thames Estuary. At Stoneness Lindberg's system had been adopted, the burner for producing the light being that of Lyth, of Stockholm. The light burned day and night at full power, showing a white light with short occultation at periods of about five seconds. A description of this system was given. The first cost of Stoneness Lighthouse had been £630, and the cost of its annual maintenance was £88. Broadness Light was produced by the combustion of compressed oil gas. The intensity of the flashes at Stoneness was about 60 candles, and at Broadness about 500 candles. The first cost of Broadness Lighthouse had been £1,026, and the cost of its annual maintenance was £128. Both Broadness and Stoneness Lighthouses were under the charge of a boatman, who visited them at least twice a week, when he adjusted and cleaned the apparatus. These systems being comparatively new, no reliable comparison had yet been made as to their relative efficiency. An important installation of an oil gas apparatus for lighting and fog signalling had recently been made by the Commissioners of Northern Lighthouses at Ailsa Craig, on the Frith of Clyde (Min. Proc. Inst.C.E., Vol. LXXXIX., page 297), the first cost of which had been £24,000, while the cost of its annual maintenance was £725. There were now 214 buoys, lightships, beacons, and other lights in use in various countries on Pintsch's system.

The author next dealt with the application of compressed oil gas to the lighting of railway carriages, which he stated was one of growing importance. It was probably first tried in the year 1871 with satisfactory results, in Germany, on the Lower

Digitized by Google

Silesian Railway, and in England in 1878 on the St. John's Wood trains of the Metropolitan Railway, with equally satisfactory results. The Great Eastern Railway Company was the next to adopt it, the Metropolitan Railway Company definitively adopted it for the whole of its rolling stock a few weeks later, and other companies quickly followed suit. The systems chosen were those of Messrs. Pintsch and Messrs. Pope & Sons, which differed but little from each other. Some trials were also made of Messrs. Bower's system on the Great Northern Railway. The gas holders were attached either to the roofs or to the under framing of the carriages, and were charged to a pressure of from 6 to 8 atmospheres. The gas was conveyed to the roof lamps by pipes from the gas holders, passing through a contrivance for regulating the pressure at the burners, one such regulator being attached to each carriage. There were now 23,499 carriages so illuminated on Pintsch's system, and 2791 on Pope's system. Taking the double journey between Euston and Aberdeen, the cost of compressed oil gas was 0·0404d. per lamp per hour, and for the ordinary oil system 0·385d. per lamp per hour, showing a greater cost of the ordinary oil system of 0·3446d. per lamp per hour, or eight and a half times more than oil gas.

AUTOMATIC DAMPER FOR BOILER FURNACES.

THE accompanying illustrations show in Fig. 1 a section and in Fig. 2 a side elevation of an automatic damper regulator, designed by Messrs. White & Carson, for controlling the consumption of fuel and the pressure of steam in boilers. The arrangement is in direct communication with the boiler or the main steam pipe, and as soon as the pressure of the steam exceeds a given limit the regulator is actuated, causing a corresponding depression of the damper. When the fires are sufficiently low, and the steam has assumed its normal pressure, the damper is raised, thereby adjusting the fires in such a manner as to maintain the required pressure in the boiler. The steam pipe E, shown in Figs. 1 and 2, is provided with a bend in which the condensed steam is retained. The steam thus condensed passes into the cylinder B and actuates the brass ram D. The motion of D is transmitted to the cone pulley A, thereby imparting a downward motion to the damper. In the column on the opposite side of the pulley is suspended a weight F, which is sufficiently heavy to raise the damper to its highest position as soon as the pressure on the ram D is relieved. The ram D is constructed in such a manner that all parts are in equilibrium so long as the normal steam pressure is maintained. If the pressure increases the ram D is actuated and the damper moved downwards, while the weight F is raised in the column. As F ascends it is gradually loaded by chains suspended from the cover of the column which collect in the space C on the top of F. These chains act as a brake, and check the too rapid ascent of F. After the fires have been sufficiently checked and the steam pressure begins to decrease, the weight F descends, and the chains again come into action, for the lower F sinks the lighter it gets in proportion to the decreased pressure on the ram. By means of this differential arrangement the damper may be moved up or down gradually, or stopped in any required position. The damper may be adjusted for slow combustion and low pressures by detaching part of the weight F, thereby economising fuel during the night or other times of partial working. This arrangement, which appears to be neatly designed, is being introduced by Messrs. J. M. Adam and Co., the Engineering Bureau, Glasgow.

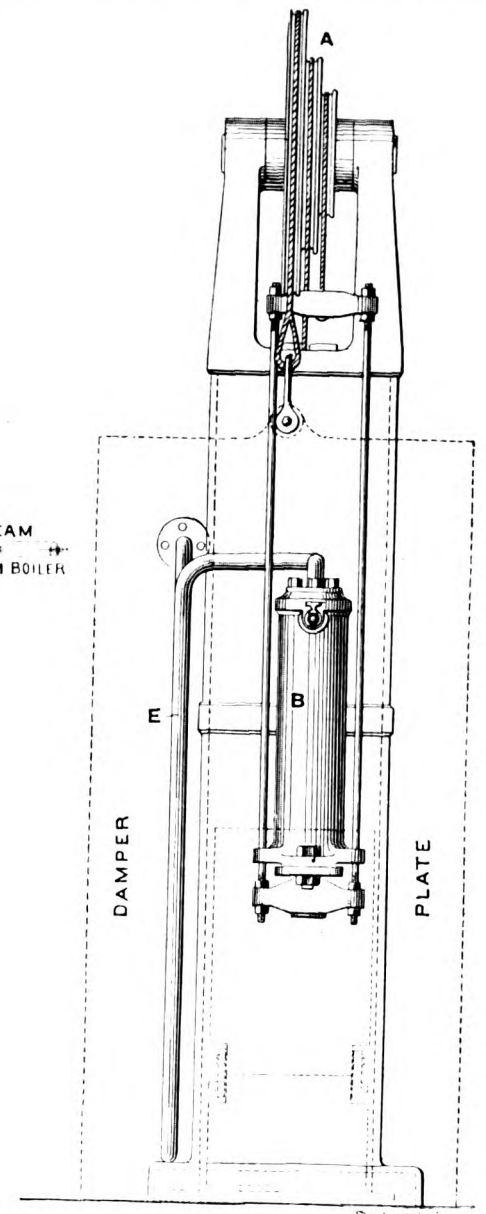

FIG. 2.

SOME RECENT OFFICIAL REPORTS ON BOILER EXPLOSIONS.

THE explosion of a small vertical boiler about 11-50 a.m. on the 13th December, 1887, belonging to Mr. S. Carnelly, Red House Farm, Kimberworth, near Rotherham, deserves the special attention of wharfingers, farmers, hay and straw dealers, and others who use small boilers intermittently, being an example of a danger not usually borne in mind, except in relation to circulating boilers for heating water, viz., the danger from frost. This boiler, which was a second hand one, having its age and maker's name unknown, was only 2ft. 5⅝in. in diameter, and contained a fire box 2ft. 1¼in. in diameter and 2ft. 10½in. high, connected to an uptake 6in. in diameter. The shell plates were $\frac{5}{16}$in. thick, and those of the fire box and uptake ⅜in. thick, all single riveted. It was provided with the usual mountings, the safety valve being loaded to about 90lb. per square inch. A farm labourer who was attending to the fire was severely scalded by the explosion, which was of a violent character, rending the shell into six pieces. There appears to be little doubt that fracture commenced at one of the vertical seams of the shell, where a crack through the rivet holes of the inside lap, 13½in. long, had existed some little time before, caused by freezing of the water in the narrow space between the fire box and shell. The boiler only worked once a week, and stood in a shed exposed to the cold air; and the water, which was allowed to remain in the boiler after the fires were drawn, had on several occasions been found frozen. This shows that great care should be taken by all those who have charge of boilers, not regularly in work and exposed to the atmosphere, to carefully empty them after ceasing work, so as to prevent the formation of ice. Care should also be taken to empty boilers during the cold season which may have been undergoing test by water pressure, as we have known several serious accidents not only to boilers, but to the cylinders of portable engines which have become filled with water during test. This explosion was the subject of preliminary inquiry No. 252. Preliminary report No. 253 deals with the explosion of a cylindrical multitubular boiler, externally fired, belonging to Messrs. Beare & Sons, tanners, Heigham-street, Norwich, which took place on the 5th December, 1887, about 7-30 a.m. The boiler was made by Messrs. Sabberton Brothers, Norwich, in 1881; it was 5ft. 3¼in. in diameter, and 11ft. 7½in. in length, made of ⅜in. plates, double riveted. The ends, which were flat, were $\frac{9}{16}$in. thick, stayed by three gusset stays at each end, and two longitudinal stays 1½in. in diameter, in addition to the support given by fifty-eight tubes 3¼in. in diameter, and it was provided with the usual mountings, the blow-off tap being at the bottom of the back end. No person was injured by the explosion. The boiler was inspected and insured by the National Boiler Insurance Company, Limited, St. Ann's Square, Manchester. The explosion was caused by overheating of the plate over the fire grate, due to the accumulation of deposit; the solid plate bulging down and opening out 14¾in. in the longitudinal direction. From an analysis made by the authorities at Somerset House, it appeared that the deposit formed by the feed water contained, among other matter, carbonate of lime, 24·62 per cent.; sulphate of magnesia, 7·67 per cent.; and carbon and organic matter, 53·66 per cent.; from which it was evident that the feed water was most unsuited for use in an externally fired boiler. By a frequent use of the blow-off tap the accumulation of deposit had previously been kept down; but owing to the absence of the regular attendant from illness, and the sinking of the foundation, so that the front of the boiler had become lower than the back, deposit in large quantities had been allowed to gather over the fire grate, with the result already detailed. Deposit of the nature described does not form into hard masses, and can easily be removed by a proper system of blowing off, particularly from the surface, as being of a light and floury character much of it will float in the form of scum, and is easily carried away by the escaping water. Or the objectionable qualities of the feed water might have been removed by the adoption of some method of water purification. A useful lesson may be drawn from this accident, and it would be well for those who through local circumstances are compelled to use such objectionable water, to well consider the type of boiler best suited for their special circumstances, as for example, in the present case, one of internally fired construction, as the worst that usually occurs in the event of bad water is simply deformation, or collapse of the furnace tube or tubes from overheating, caused by deposit; whereas, in an externally fired boiler, the result, as in the case under notice, is generally rupture and explosion. There is no doubt that in an exceptional case of bad feed water sufficient deposit might be formed, and accumulate on the furnace crown even of an internally fired boiler, to produce serious injury; but the form of the surface and the motion of the water from ebullition and circulation, do not favour retention so well as in the case of an externally fired boiler, where all the deposit must necessarily settle along the bottom, exposed to the fire or heated gases. Practice shows that an internally fired boiler will work satisfactorily, or at the worst with slight recurring leakage from the furnace seams, using water which would produce overheating, fracture, and possibly explosion of a boiler externally fired; and in laying down new plant, embodying steam power, no point requires

more careful attention than the quality and nature of the available supply of feed water. This question is very often passed over, and, in some cases, entirely neglected, thereby involving increased coal bills, expensive repairs to boilers, loss of wages, and not infrequently serious accident.

HENDERSON'S MECHANICAL STOKER.

THE accompanying illustrations show in Fig. 1 the elevation, and in Fig. 2 the longitudinal section of a patent mechanical stoker and self cleaning furnace invented by Mr. Thomas Henderson, 40, Castle-street, Liverpool. The power is supplied to the apparatus by means of a belt, and fast and loose pulleys secured to a horizontal shaft, shown in Fig. 1. This shaft is provided with a worm gearing into the worm wheel B (Fig 1), which is attached to a vertical shaft carrying the worms A and C. The worm A engages with a worm wheel secured to a horizontal shaft by means of which the fuel crushers are actuated, which break the coal into pieces of suitable size. Below these crushers four fans are arranged, and a plate, which is adjustable by means of a screw, is interposed between the crushers and fans for regulating the supply of coal. The fans are revolved in opposite directions by friction pulleys attached to the main shaft, and distribute the broken up fuel in a suitable manner over the front of the grate. The worm C secured to the lower end of the vertical shaft engages with a worm wheel attached to a short horizontal shaft, to which the grate bars are connected by a simple rocking or cradle arrangement, shown in Fig. 2. By means of this rocking arrangement one half of the number of grate bars are moved up and down, thereby breaking up the clinker; while the rest of the grate bars receive a reciprocating motion, thereby conveying the clinker and other refuse to the back end of the furnace—depositing it over the end of the fire bars into the combustion chamber. The deposit when cold is removed from the combustion chamber through a damper door below the end of the fire bars. The fire bars of each furnace may be thrown out of gear by means of thumb screws fitted into the cranks. A clutch arrangement is also provided, by means of which the gear actuating the fire bars is disengaged from the feed apparatus in such a manner that the latter stands still while the former continues to work. The fire doors are arranged so as to allow hand firing to take the place of the automatic supply in case of the feeding apparatus getting out of order. The clutch mentioned above is then disengaged, and the feeding apparatus stopped and repaired, while the fire bars continue to break up and clean the fires, so that no interruption of the working of the boiler is experienced. The tests shown in the above table were carried out at the instance of Mr. W. Armstrong, and all the observations were made by Mr. W. J. Bird.

THE MANCHESTER ROYAL JUBILEE EXHIBITION.

TEXTILE MACHINERY *(continued from page 367).*—A loom exhibited by Mr. Wright Shaw, Bredbury, had an ingenious drop box motion, which had several points of interest, but which it is difficult to describe without illustrations. In this case, the whole of the lifting hooks are placed at the top of the loom, and it is therefore much more easy to get at them. There is an ingenious arrangement of discs by which the pattern chain may be stopped, and any even number of picks woven from one card—the length of the chain being thus economised. A double lift is obtained by means of cams, which can be thrown into action when desired, and long helical springs are used to help the changes, and enable them to be made without shock. The machine was well designed, and strongly constructed.

Messrs. Harling & Todd, Burnley, exhibited a loom fitted with the motion illustrated in Fig. 71. The boxes

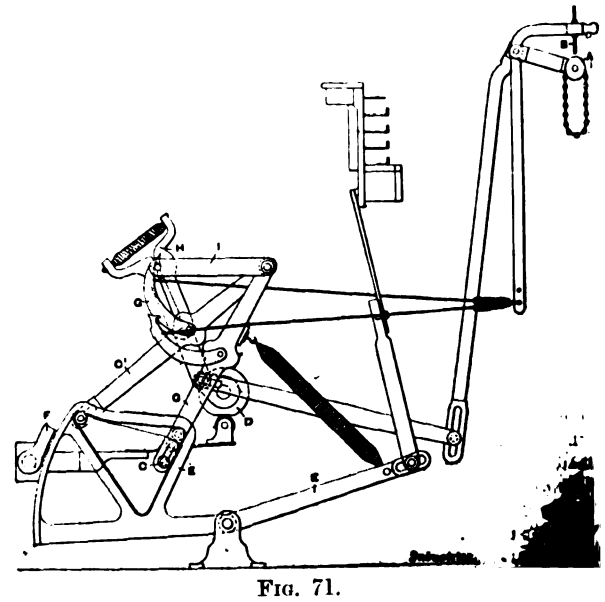

FIG. 71.

are sustained at the end of a vertical lever, which is jointed to the rocking lever E. E is formed with a quadrant at one end, the shape of which is utilised in lifting the boxes. The pattern chain A is fixed at the end of a lever, and is oscillated by the crank D. The hooks G are pivoted as shown, and are connected with

Digitized by Google

the lower ends of levers, to which the needles B are attached. The hooks, needles, and their connecting levers correspond in number to the number of boxes. A catch plate I is continually reciprocated from the crank D by means of the lever H, which is formed with a forked arm held together by a strong spiral spring. Four levers C C^1 are pivoted from the plate I, each of them being of a different length, so as to engage with various parts of the quadrant on the end of E. A brake F is fixed to one end of the lever shown, which carries, by means of a strong flat spring, a bowl kept in contact with a revolving roller or cam with a flat formed on it. The action is as follows: If the needle B is pushed by the motion of A, its corresponding catch G is drawn and engaged with the catch plate I. In this way the movement is communicated to the lever C, to which G is attached, and the lower end of the lever is caused to pull the quadrant, and so cause the lever E to oscillate and raise or lower the box. When the box is being lifted, the cam surface, acting on the bowl in touch with it, releases F from its contact with the quadrant; but as soon as the change of box is made, F again acts as a brake, and holds the lever E steady. The motion is positive, and in case of an obstruction the forked lever H opens and allows the catch plate to be pulled downwards, thus obviating the risk of breakage.

Messrs. Butterworth & Dickinson, Burnley, showed Catlow's patent dobby, which is illustrated in Fig. 72, as applied to a strong calico loom. This dobby is a double lift one, thus obtaining a wide shed, and the use of two lattice barrels connected by gearing so that they both revolve in the same direction. The jack lever is attached to the vertical levers, the top and bottom catches being worked respectively by the two barrels, and connected with the ends of the levers. To each of these catches a light blade spring is attached, which insures them being sprung upon the top of the knife, and thereby obtaining a certain lift. A series of wooden jacks or levers are employed, so as to give a varying lift to the front and back healds, in this way keeping the yarn in even tension, and preventing slack sheds. The healds are drawn down by means of a series of levers adjoining one another, and worked by means of a rocking bar driven from the tappet shaft. When the shed is being formed, the jacks are pushed down until it is fully open, and the warp is thus drawn down with the same certainty as the upward movement is made.

Messrs. Willan & Mills, Blackburn, exhibited Jepson's dobby. The lattice barrel is driven by a ratchet feed, and the motion of the healds is obtained through levers and rods. A brass pulley is placed at the bottom of the loom framing, being formed with an indent, into which a projection made on a hanging lever falls. To the lever is attached a wire, which at its other end is connected with the pawl working the chain barrel. By placing a peg in the lattice at the proper point the pawl is raised, and the projection is thus lifted out of the indent in the pulley. The latter then begins to revolve, and the projection resting on the plain part of the pulley retains the catch in its lifted position. When the indent again comes under the projection, the latter again falls and holds the pulley. The same movement puts the pawl into the ratchet on the barrel spindle, and the rotation of the chain is re-commenced. By regulating the speed of the brass pulley with change wheels, any plain length can be woven, an arrangement which is in many cases very convenient.

Several examples of looms with the Bradford style of treading by means of side tappets were shown; but these are so well known that special reference to them is not necessary. Messrs. Platt Brothers & Co., Oldham, showed a velvet loom, in which Nuttal's patent oscillating tappets were used. By combining two chains, the necessary changes could be made without the use of the long chains which are ordinarily essential.

In this great exhibition of textile machinery we naturally looked for some examples of jacquard machines, and the most complete show of these was made by Messrs. Devoge & Co., Manchester. The principle of these machines is well known, and includes the use of a number of vertical rods hooked at their upper end, which are connected with the warp threads, and are lifted by a knife or "griff," having a constant vertically reciprocating movement. The hooks are pushed out of the way of the griff by means of needles, actuated by a pattern card passing over a barrel. The barrel has a horizontal or radial movement to and fro, and in some cases there are two barrels, one on each side, so that with the same number of hooks a double effect can be produced. By means of a cord from below, either cylinder can be thrown out of gear. There were several patterns exhibited by Messrs. Devoge, of all sizes, including a machine for double shedding, which is especially desirable where large shuttles are being used. The comber board slip shown by this firm is also a notable feature, inasmuch as the space between the holes is much increased, and the risk of wearing through is overcome. This has been a great source of mischief in the old type, and the remedy for it is of importance. The machine shown in motion worked smoothly at a speed of two hundred picks per minute.

THE MANCHESTER ROYAL JUBILEE EXHIBITION.

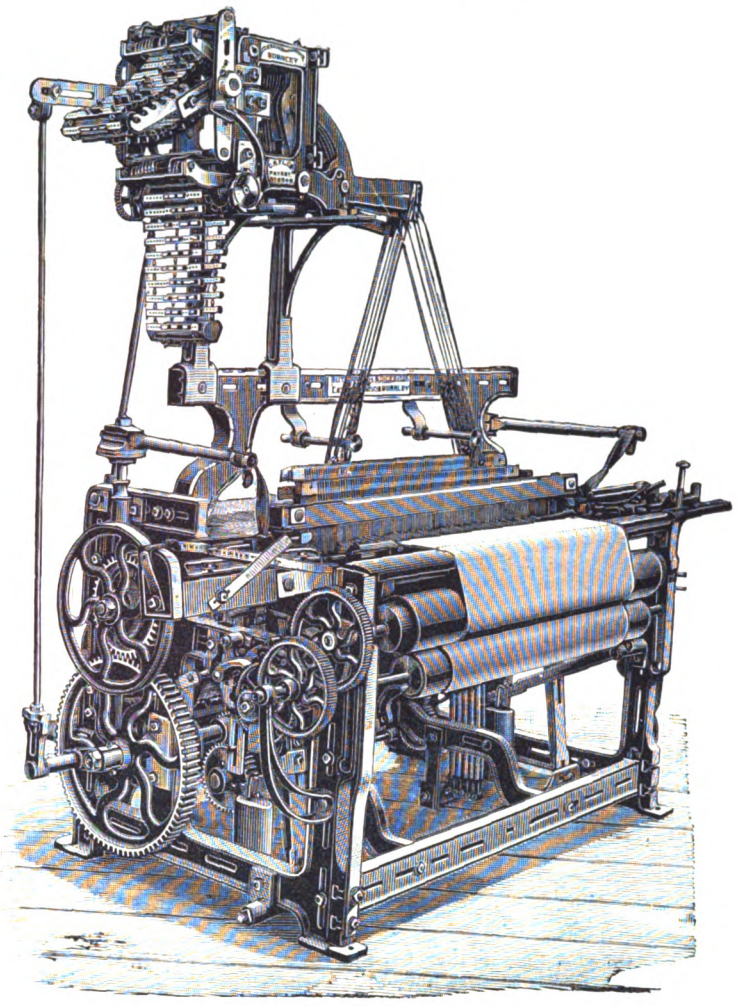

Fig. 72.

Messrs. J. H. Riley & Co., Bury, showed a beetling machine, which was fitted with forty fallers of beech, lifted by three-winged wooden tappets in the usual way. They also exhibited a four-bowl calender, which was large enough to deal with cloth 40in. wide. The bowls were four in number, two being made of pressed cotton, one cast iron, and one hollow bright chilled bowl. By means of a special gas heating device, to which an injector of peculiar coustruction was applied, the chilled bowl was heated effectually. The machine was very massive and well fitted. Special arrangements were provided for lifting the top bowl out of contact when desired, in order to give a special finish. It was geared with a helical wheel on the chilled bowl, driven by a pinion fixed on a short shaft 5in. diam. The driving was effected by Hunter's patent clutch, which can be easily handled, and enables a few inches of cloth only to be passed through the machine. A stretching machine was also exhibited by this firm, in which two pulleys, the axes of which can be arranged at an angle to each other, are employed. The revolution of the pulleys while the cloth is passing over them draws it tight sideways, and so restores the width lost in bleaching.

Mr. Birch also exhibited a patent squeezer, which consists of a disc mounted on a shaft, and having its periphery formed with a square groove, from the outer edge of which to the periphery the disc is bevelled, so as to gently guide the cloth into the groove. A second disc, wide enough to go easily into the groove, is forced up to the latter by means of a lever, a spring being fitted to insure against over-pressure. The cloth being passed into the groove in the form of a loose rope, is, when the pressure is applied, effectually squeezed.

(To be continued.)

ARMY AND NAVY CONTRACTS.

The question as to the advisability of publishing the prices quoted in tenders accepted by the War Office and Admiralty having been raised, these Government departments addressed 103 firms and 70 chambers of commerce on the subject. From the latter 48 replies have been received, of which 24 are on the side of publicity, 20 against it, and 4 neutral; the 20 chambers opposed to publicity, however, include the chief manufacturing districts in the kingdom, while the others are of a more general commercial character not so directly concerned in Government contracts. The replies received from the manufacturers themselves are almost entirely in favour of secrecy, some twenty different reasons being assigned. Taking the replies received at the Admiralty from 61 manufacturers, we find the reasons given for privacy are as follow: (1) That it is not in accordance with trade usages. (2) That manufacturers, for various reasons, such, for example, as a desire to keep their workmen employed, the magnitude of orders, security against bad debts, and prestige of holding Government contracts, constantly quote to the Government departments much lower rates than those quoted to private customers, who would learn the Government rates and demand them. To such an extent is this felt that many firms would cease to do business with the Government if the publication of prices were permitted, or be compelled to raise their prices. (3) That the publication of prices would enable cutting firms to put in a price just below what was last accepted, and one probably which is unremunerative, for reasons given before. They would recoup themselves, or try to do it, by inferiority of quality. (4) That contractors would find greater difficulty in buying the raw material, and in dealing with their workpeople. (5) That occasionally the department might be compelled to accept a tender which was not the lowest. It would have to justify its action to disappointed competitors, by stating what it thought about their character, and endless correspondence would arise. The effect would be that those persons who have to adjudicate upon tenders would be tempted to neglect every consideration excepting price. (6) That the practice of publishing prices in foreign countries throws the business into the hands of third or fourth rate houses and agents. The second point is that on which most stress is laid, and the third is one which even firms not engaged in Government work, but who have experienced the opposition of inferior manufacturers, who constantly quote prices which can hardly leave any margin of profit, will readily appreciate. In six replies received by the Admiralty in favour of publicity no reasons were assigned. The official view of the matter is, that though some of the arguments advanced affect the individual contractor rather than the State at large, yet that the Departments would ultimately suffer in most cases, and the general opinion of manufacturers clearly shows the advisability of continuing the present system of treating tenders as confidential.

FOREIGN INDUSTRIES.

(From our own Correspondents.)

PARIS, 17th April, 1888.

The Iron Market.—Judged by the amount of business transacted, the iron market appears in a state of languor; but when we take account of the steadily advancing prices we must regard the situation as on the whole satisfactory. The firm attitude of the manufacturers of the North has had a strengthening effect upon the trade generally, and upon the markets here in particular. The merchants have recovered from their fright, and instead of selling below the syndicate quotations, have issued circulars announcing a further advance in bars and joists. Now that the prospect has grown clear again, we may expect renewed activity. The principal obstacle to the revival of business is the uncertainty of the political situation. The reality of the advance which has been made in prices is shown by two contracts tendered for last week. One was for pipes for the Telegraph Department, and the other for railway chairs for the State railways. The tenders showed an increase of 8s. a ton on former prices. In the Haute-Marne wire and wire nails are still in strong demand. In the Nord plates are actively sought after. In the Ardennes building iron and hardware are the classes of goods chiefly dealt in. There is also some life in the business in malleable castings.

The Metal Market.—The syndicate is still able to maintain the price of copper, in spite of increasing stocks and restricted consumption. Tin stocks, too, accumulate steadily, but prices do not give way in any serious degree. There has been large buying of lead on German account, which has imparted strength to the market for the moment. Consumers of spelter restrict their purchases to present needs in anticipation of lower prices. Like copper, zinc has become too dear for many uses to which it was formerly applied.

Proportions of Steam Boilers.—M. D. Stapfer, finding that no precise rules have ever been laid down in practical hand books on boiler construction, has collected a large number of designs of boilers in actual use, and working under favourable conditions, with a view to deduce such rules for future guidance. The water level, he says, of ordinary land boilers, and in boilers for torpedo boats, is usually fixed at two-thirds of the diameter, and in marine boilers and also in those of the locomotive type at three-fourths of the diameter; but the level or evaporating surface ought to be proportional to the steam pressure, being larger for higher steam pressures. This surface should be at least 1·50 square metres for a production of 100 kilo. of steam per hour when the boiler is to work under a pressure of 1 atmosphere, and may be reduced to 0·30 square metres at 5 atmospheres, and to 0·15 square metres at 10 atmospheres. Hence the reduction of the dimensions of marine boilers to be used with the new triple expansion engines. The capacity of the steam reservoir should be determined, not by the power of the boiler, but by the dimensions of the engine cylinders. A good proportion is one hundred times the capacity of the cylinders. The sectional area of the flues and tubes should be one-sixth of that of the grate surface when the draught is produced by a chimney from 8m. to 10m. in height, a draught corresponding to a consumption of 60 kilo. of coal per square metre of grate. This proportion is reduced to one-tenth in boilers working under forced draught. In non-tubular boilers, however, the proportion is to be increased to one-third or one-fourth.

BERLIN, 16th April, 1888.

The Iron Market.—The great activity in the iron market during the last few months is now giving way to a steady trade, without, however, any diminution in prices taking place. In Upper Silesia there were twenty-seven blast furnaces in operation at the end of the first quarter of the year. One of the furnaces at the Falvahütte has been shut down, and the reduction of output thus occasioned will in part be compensated by pressing the remaining furnaces harder. The new furnace for this works will not be ready until far on in the present quarter. One of the new furnaces at the Friedenshütte is to be put in blast very shortly, and an additional furnace for charcoal iron has been started at the Bruschiek works. Foundries continue to be well employed, and some rolling mills are working night shifts. Forge pig remains firm, at from 50s. to 54s., and the better qualities of foundry pig fetch from 56s. to 60s. The export trade is still languishing, and there is hardly any business done over the eastern frontier.

The Exhibition of Small Motors at Munich.—Applications for space for this Exhibition, which is to be held from the 1st of August to the 15th of October, have being received by the committee in great numbers, and it has been found necessary to enlarge the space originally reserved for the exhibits by the addition of side galleries. Nearly every important system of gas engine, domestic, steam, or hot air engine has been entered, and machine tool makers have also responded to the invitation in considerable numbers. The railway companies have made the concession of returning, carriage free, to the exhibitors any article which may remain unsold at the close of the Exhibition. The cost of the prizes will be borne by the Bavarian Government.

Telephony.—The question of right of way for underground telephone wires in the streets of Berlin has been debated between the Town Council and the postal authorities for some considerable time, the latter claiming the right to lay cables through any thoroughfare, and the former refusing it. The matter has at last been settled, and, under the new agreement, the Post Office will be able to put as many wires underground as they think fit. This will greatly relieve the overhead system, which had already threatened to become unmanageable, on account of the multiplication of circuits. The total number of telephone subscribers in Berlin is now about 10,000, and the tendency is still to increase.

Wood Paving.—In recent years the town authorities of Berlin and Hamburg have largely experimented with wood paving, in order to determine the best materials to be employed, and the most suitable methods of laying the blocks. The first trials made in Berlin were with American yellow pine and cypress wood, after which various portions of the town were experimentally laid with unimpregnated German and Swedish pine, with impregnated pine, and with impregnated German beech. These experiments have shown that unimpregnated pine is totally unsuitable for paving purposes, whilst impregnated pine offers greater resistance to the influence of the weather. Beech is preferable to pine as being harder, but there is some difficulty in the impregnation. American wood without any impregnation has up to the present been found most successful, and resists climatic influences because of its being hard, fatty, and resinous. The total quantity of wood pavement laid down in Berlin at the end of last year amounted to 50,000 square yards, but recently the tendency is to give asphalt the preference, and wood is not used for new streets.

Water Gas.—The use of water gas for heating and lighting purposes is steadily extending throughout Germany. This gas has been employed with satisfactory results in various iron and chemical works, also for lime kilns and glass works. At the works of Messrs. Schulz, Knaudt, and Co., in Essen, there are two generators in use, each of a capacity of 500 cubic metres per hour, and the gas is used for the welding of boiler flues and for lighting, a total of 900 lights being supplied. At the Witkowitz works there are three generators, each of 500 cubic metres capacity, and the gas is used in two Martin furnaces and for lighting. Messrs. J. Pintsch & Co., in their works at Fürstenwalde, use water gas for the welding of the steel reservoirs required for compound oil gas, and they also supply water gas for lighting the railway station. The station of Königszelt is also lighted by water gas, and in Frankfort-on-the-Main water gas is used for the smelting of gold and silver.

VIENNA, 16th April, 1888.

The Iron Market.—The improvement in the iron market which I reported in my last letter as having set in with the change of the weather, appears to be progressive, and the situation becomes better from day to day. The building trades are specially brisk, and large quantities of girders and other building iron are required. This is partly due to the destruction of buildings in Hungary during the recent floods, but there is also a movement of centralisation going on, large numbers of persons from the country flocking to the towns, and the additional accommodation required influences the iron market favourably. In sympathy with the rolled iron market, the crude iron market is also firm. Engineering works are fairly well employed, particularly with agricultural machinery and with orders for the sugar factories. The large engineering works of Messrs. Ganz & Co., of Buda-Pesth, with branch establishments in Leobersdorf, Austria, and in Ratibor, Prussia, are very busy with milling machinery, railway wheels and waggons, and electrical machinery. During the last financial year the total value of the goods turned out amounted to 5,400,000 florins (about £430,000), and the net profit was 440,000 florins (about £35,000). A dividend of 55 florins per share has been declared. A peculiar feature of the company is a pension fund for their employés, to which 93,000 florins (£7,500) have been transferred from the profits.

Metals.—Owing to heavy orders from sugar factories and other industrial establishments for machinery in which copper is required, the present demand for copper on the part of engineering works is very brisk, and considerable quantities of this metal are required. The stocks of old copper have hitherto been sufficiently large to prevent this demand from further increasing the prices of the copper syndicate; but these stocks are now almost exhausted, and consumers are forced to come into the market for new copper. They do not evince any eagerness for making large purchases, as the general opinion here is that the copper syndicate will not be able to hold out much longer, and consumers therefore prefer to delay giving their orders as much as possible. There is a great scarcity of the better quality of copper required for gun metal and brass work. A good trade is being done in so-called copper vessels for the Oriental market; but these are in reality an imitation, being made of zinc with a copper coating deposited electrolytically. There is an abundance of copper ores in the country, but unfortunately they are too poor to pay for smelting, and mine owners are now turning their attention to the electrolytic process, by which the exploitation of the poor ores is thought to be possible. Amongst these mine owners, I may mention Messrs. Tlach & Keil, of Troppau, who have adopted an electrolytic process. There is also a copper mine in Servia owned by Austrian capitalists where the poor ore is worked up electrolytically. Some rich lodes of silver have been found in the Hungarian Government mine at Vihnye. The old and hitherto disused silver mine of Klostergrab in Bohemia has been bought by a private company, and is to be re-opened. The ores are poor, but it is hoped that they can be profitably worked by an electrolytic process. The necessary machinery is to be ordered from Messrs. Siemens and Halske.

Textiles.—After a slight drop in prices which took place a fortnight ago the market has shown no signs of receding further, but weavers are still reluctant to place large orders at the present prices of yarns. The demand for cotton goods is fairly brisk, and English goods are specially in request. In cloth and woollen goods the market is very languid. Silks are in favour, as are also worsteds and trimmings. Although efforts have been made for years to emancipate Austrian textile industries from foreign imports, we still depend to a large extent upon England for our wants in textiles. I have collected the following figures regarding the import and export of textiles, and these will be found specially interesting, as they show that notwithstanding the increase in our import duties which took place after 1886, the quantities imported have not sensibly diminished. The diminution in cotton goods amounts to only 1·6 per cent., and in jute to 6·8 per cent. On the other hand, the importation of woollen goods has increased 6·9 per cent., and that of linen goods 23·8 per cent. The quantities are given in tons. As regards the export of textiles, there is a diminution of 3·3 per cent. in linen goods, and of 30·2 per cent. in woollen goods, whilst cottons have only very slightly increased.

Cotton yarn	479	483

BRUSSELS, 17th April, 1888.

The Coal Market.—Business is brisk in smiths' coals, coke, and coke dust. The new tariffs of the Belgian Grand Central Railway in connection with the Rhenish and Westphalian railways for coke, briquettes, and metallurgical products, are about to come into force, and will enable the Germans to regain the ground they have lost during the past two years, unless the Belgian Government promptly takes action to counterbalance this movement. The market is firm at Liège, Charleroi, and Mons, prices being well maintained. In these districts colliery owners have decided not to make long contracts, except at an advance of 5d. per ton. Present quotations are: 12s. for screened coal, 8s. for unscreened, and 6s. 10d. to 7s. 2d. for coke dust.

The Iron Market.—The pig iron market is well maintained. The Malines works have an order for 1000 tons of iron piles, and the Monceau works have 500 tons of iron work in connection with the same. Cockerill has received a large order for rails. There is a good demand for finished iron, especially girders; but difficulties are still caused by the dearness and scarcity of the raw material. Mine owners in Luxemburg have been disturbed by the news that our blast furnaces are to obtain part of their ore from the Haute-Moselle. A representative of the group of blast furnaces, who has inquired into the subject in the neighbourhood of Nancy, reports that in two months ore can be sent to Belgium at the rate of 600,000 tons per year, and that this business could be later developed to supply 1,470,000 tons per year, or more than is obtained at present from Luxemburg by our blast furnaces. There is no doubt that the imports from the Moselle district will largely increase.

Glass Works.—The situation has improved slightly, the fall in the English market having ceased, and some important orders having been received from the country. There is still a good demand from the United States. Inquiries have been received from Japan and China, but buyers there are not able to pay the prices owing to the rates of exchange. The annual report of the Société Anonyme of Charleroi shows a profit for 1887 of £2,906, out of which a dividend of 2 per cent. will be paid.

Textiles.—There has been absolutely nothing done in Russian flax and hemp during the past week, and the price of other foreign hemps is falling. There is a demand for the better qualities of flax, but yarns are not inquired for.

Electric Lighting.—The Belgian Society of Electricians have offered a reward of £10 for the best elementary essay on applied electricity. Either members or non-members of the Society, irrespective of nationality, may compete for this prize, and the essay must be written in such a way that persons of ordinary education and ignorant of the science of electricity may understand it. Messrs. Mourlon Frères of this town are now pushing an American petroleum engine for domestic electric light installations, and several exhibits will be on view at the forthcoming Exhibition, where they will be employed for lighting some cafés and restaurants in the gardens. An interesting novelty, for Belgian visitors at least, will be high power incandescent lamps ranging from 200 to 1200 candles. In my letter of the 13th March I gave some particulars of the illuminated fountains which will be used at this Exhibition. Since then the work has

Digitized by Google

been actively pushed forward, and some preliminary trials made with great success. Complaints are being made in connection with the electric lighting of the interior of the Exhibition, as it is now considered probable that the contracts will be reduced to one hundred lighting hours.

Electric Tram Cars.—The Société l'Electrique have entered a protest against M. Michelet's report attributing the deficit on last year's working to the electric traction. They say that if there is a loss, it is due to the bad management of the tramway company, which wasted a large amount of money on the charging station in the Rue Juste-Lips. In addition, the expense of working a station intended for at least forty cars has been debited to two cars only. They consequently consider that the report does not give a fair idea of the real cost of electric traction, which is as cheap as horse traction. In order to prove this the Société l'Electrique are willing to contract for electric traction, and if the tramway company refuse the offer their conduct could only be explained on the score of prejudice on their part against electricity in any shape or form.

DÜSSELDORF, 16th April, 1888.

The Coal Market.—The coal market is still distinguished by a degree of activity unusual at this season of the year. The demand for house coal is falling off; but a very animated business is being done in the industrial sorts, and prices are buoyant. Coke for metallurgical purposes cannot be produced fast enough to satisfy the demand. This larger consumption of fuel is the best possible evidence of reviving industry. Though the output from the German mines is considerably greater than in the early months of last year, foreign coal is being bought in larger quantities. From the Customs returns just issued it appears that in the first two months of the current year the imports were 618,479 (552,544) tons of "brown" coal (lignite); 327,250 (231,474) tons of "black" coal; 44,963 (36,704) tons of coke; and 4333 (3301) tons of artificial fuel, a total of 995,025 (824,023) tons, the quantities within brackets being those for the corresponding period of 1887. The increase in the coal imports is chiefly observable in the trade with England. The exports of German coal in the two months' period amounted to 1,450,361 (1,441,206) tons; 133,831 (116,827) tons of coke; and 23,318 (23,428) tons of artificial fuel, besides 2106 (1293) tons of lignite, a total quantity of 1,599,616 (1,582,754) tons. Thus we have an increase of 20·75 per cent. in the imports and 1·07 per cent. in the exports.

The Iron Market.—The iron market has not materially changed since my last report. The calm which has come upon it is likely to be of long duration, for consumers have bought far forward into the year, and prices, being dependent upon well organised syndicates, are too firmly established to give way for some months to come. At the last meeting of the Pig Iron Association, held at Cologne, measures were taken to insure, by means of heavy fines for infraction, observance of the regulation on the part of the merchants. There is a steady, but by no means animated, demand for pig iron, no class being actively sought after. Prices are as follow: Spiegel pig of 10 to 12 per cent. manganese, 59s.; forge, 51s. to 52s.; white steel pig is quoted the same as forge; basic steel pig, 45s. to 46s.; Bessemer pig, 54s. to 54s. 6d.; Luxemburg forge, 38s. 7d.; and foundry pig, No. 1, 57s. per ton. English pig is arriving in considerable quantities. The exports from Great Britain to Germany and Holland in the first quarter of the current year amounted to 62,513 tons, against 52,480 tons in 1887, and 40,974 tons in 1886. The average declared value per ton is 38s. 9d., against 40s. 5½d. and 35s. 11½d. in the two previous years respectively. The market for finished iron shows a little more animation, bars being more inquired after. There is a brisk demand for joists, and an average amount of business is being done in plates, both of the common and the boiler classes. For all other goods the market is very quiet. Founders are fairly busy. The lowest tender for 118 tons of cast iron pipes for the railway at Kassel last week was £600. The latest quotations for finished iron and steel are as follow: Merchant bars, £6. 5s. to £6. 7s. 6d.; angles, £6. 15s.; common plates, £7. 5s.; boiler plates, £8. 5s.; Siegen sheets, £7. 10s. to £7. 12s.; hoops, £6. 17s. 6d. to £7; common steel plates, about £6. 18s.; steel billets, £6. 15s.; drawn iron wire, £7; rolled (wire nail quality), £6. 1s.; drawn steel wire, £7; rolled, £6; wire nails, £8. 5s. per ton. These prices are for Germany. Considerable concessions are made to foreign buyers.

Shipbuilding and the Iron Industry.—The iron industry of this district is beginning to feel the influence of the growth which is taking place in our shipbuilding yards. A short time ago, the Hamburg-American Steamship Company gave an order for a large steamer to the Vulcan Works at Stettin. Now, the Bremen Lloyd, which hitherto has had all its ships built in English yards, has placed with the same works an order for a second fast steamer. These two vessels represent a cost of £400,000. The Vulcan Company has purchased the whole of the steel for these vessels, amounting to 7500 tons, from one of the works of this locality.

LILLE, 17th April, 1888.

Textile Manufactures.—There has been greater activity this week in the markets for textile goods. Linen fabrics have been in fairly brisk demand; prices have, however, not become sensibly stronger. In cotton goods there is also more life, though the market is far from buoyant. These changes may mean no more than an adjustment of affairs, the course of which has been recently disturbed, or they may indicate a genuine revival of business. Most persons incline to the latter view. The week has been marked by a spurt in the wool trade. Manufacturers have bought largely, and speculators have helped forward the movement with some effect, seeing that prices have been advanced 25 centimes per kilogramme; but as the manufacturers refused to follow the rise above 10 centimes, it must be concluded that this advance is not justified by the state of trade, and that accordingly a relapse will probably occur. The trade in woollen fabrics shows a little more life, and orders are coming to hand more plentifully.

Flax and Yarn Market.—The flax market is very dull. Only a few transactions, and those unimportant, have taken place within the last two weeks either in home grown or in Russian produce. Reports of similar inactivity have been received concerning the market at Ghent. Tows are also almost wholly neglected. The situation remains unchanged for linen yarns. Spinners have enough to do to meet the demands of consumers for the present, and refuse to accept the lower prices which weavers say are necessary for the expansion of business. Jute yarns are still much sought after. Cotton spinners also firmly maintain their prices, in spite of the resistance offered by buyers. The Association of German Wool Spinners has uttered a vigorous protest against the speculative dealings which distinguish the new wool market at Antwerp, on the ground that such dealings are injurious to trade, by the constant fluctuations in prices which they occasion.

The Iron Market.—Though the iron market is not animated there is a steady course of business, which has suffered no check from the fresh advance in prices announced last week. On the contrary, the determined attitude taken up by the manufacturers has stimulated the market, consumers being now convinced that the weakness reported from Paris is only a temporary circumstance of merely local interest. Bars and joists are being bought in considerable quantities, the former at £5. 12s., the latter at £5. 4s.; but the chief demand is for plates, which are soon likely to advance beyond their present price of £6. 8s. The Tobergues Steel Works, which import large quantities of Spanish ores, have obtained from the Northern Railway Company a reduction of carriage from 2·50fr. per ton from the port of Dunkirk to 1·85fr.

Prohibition of Foreign Materials.—The Prefect of the Nord has addressed a circular to the engineer-in-chief of that department, forbidding for the future the use of foreign materials in the Government works executed under his supervision. In taking this step, which is generally regarded with approval, M. Saisset-Schneider has followed the example of the Prefect of the adjoining department of the Pas de Calais.

MADRID, 16th April, 1888.

Phosphate Mines.—A Belgian company has acquired the phosphate mines of Jumilla, which are estimated to contain 5,000,000 tons of apatite, and they expect to do an extensive business at present prices. A very favourable report was made on the mines by M. Grandeau, who surveyed them on behalf of the purchasers. Several other phosphate mines are now in the market, but they have not got the same facilities for exporting at low cost as the Jumilla mines possess.

The Barcelona Exhibition.—Advices from Barcelona state that, although the Exhibition has been officially opened, it is still in such an incomplete condition that it will be hardly worth while visiting it before the middle of June. There is no doubt, however, it will prove successful later on, many important novelties being amongst the exhibits. The large hotel, to which I have previously referred, and which can accommodate one thousand visitors, is now completed. The total time occupied from the cutting of the first sod to the final completion was 125 days. The building occupies a site of 152m. by 35m., on ground reclaimed from the sea. This ground is very valuable, and it is intended to pull down the hotel as soon as the Exhibition is over, and to use the site for other purposes. The hotel is only three storeys high. The constructor's time book shows 48,000 working days of masons and assistants, 6500 working days of joiners, and 8000 working days of painters, plumbers, &c. About 6,000,000 bricks and 800 tons of iron have been used.

Railways.—It is stated that an English house is making proposals to the Government to obtain the concession of three lines of railway in the province of Cadiz, to be constructed on the one-metre gauge. At present agriculture in this province is in a backward state, but the construction of these railways is likely to be followed up by agricultural and industrial improvements.

NEW YORK, 7th April, 1888.

The Coal Market.—The situation is less satisfactory now than it was during the miners' strike. The demand is not good, and prices have decreased from 10c. to 50c. per ton below circular rates in New York. The future depends entirely on whether the companies can agree upon the output for the present year. It is known beyond doubt that the Pennsylvania Railroad Company will not enter into any agreement either as to production or price, but it is not believed that they will interfere with any arrangements the other companies may make. In the coke market orders are scarce, and as manufacturers are not anxious to make contracts at present rates, the outlook is decidedly bad.

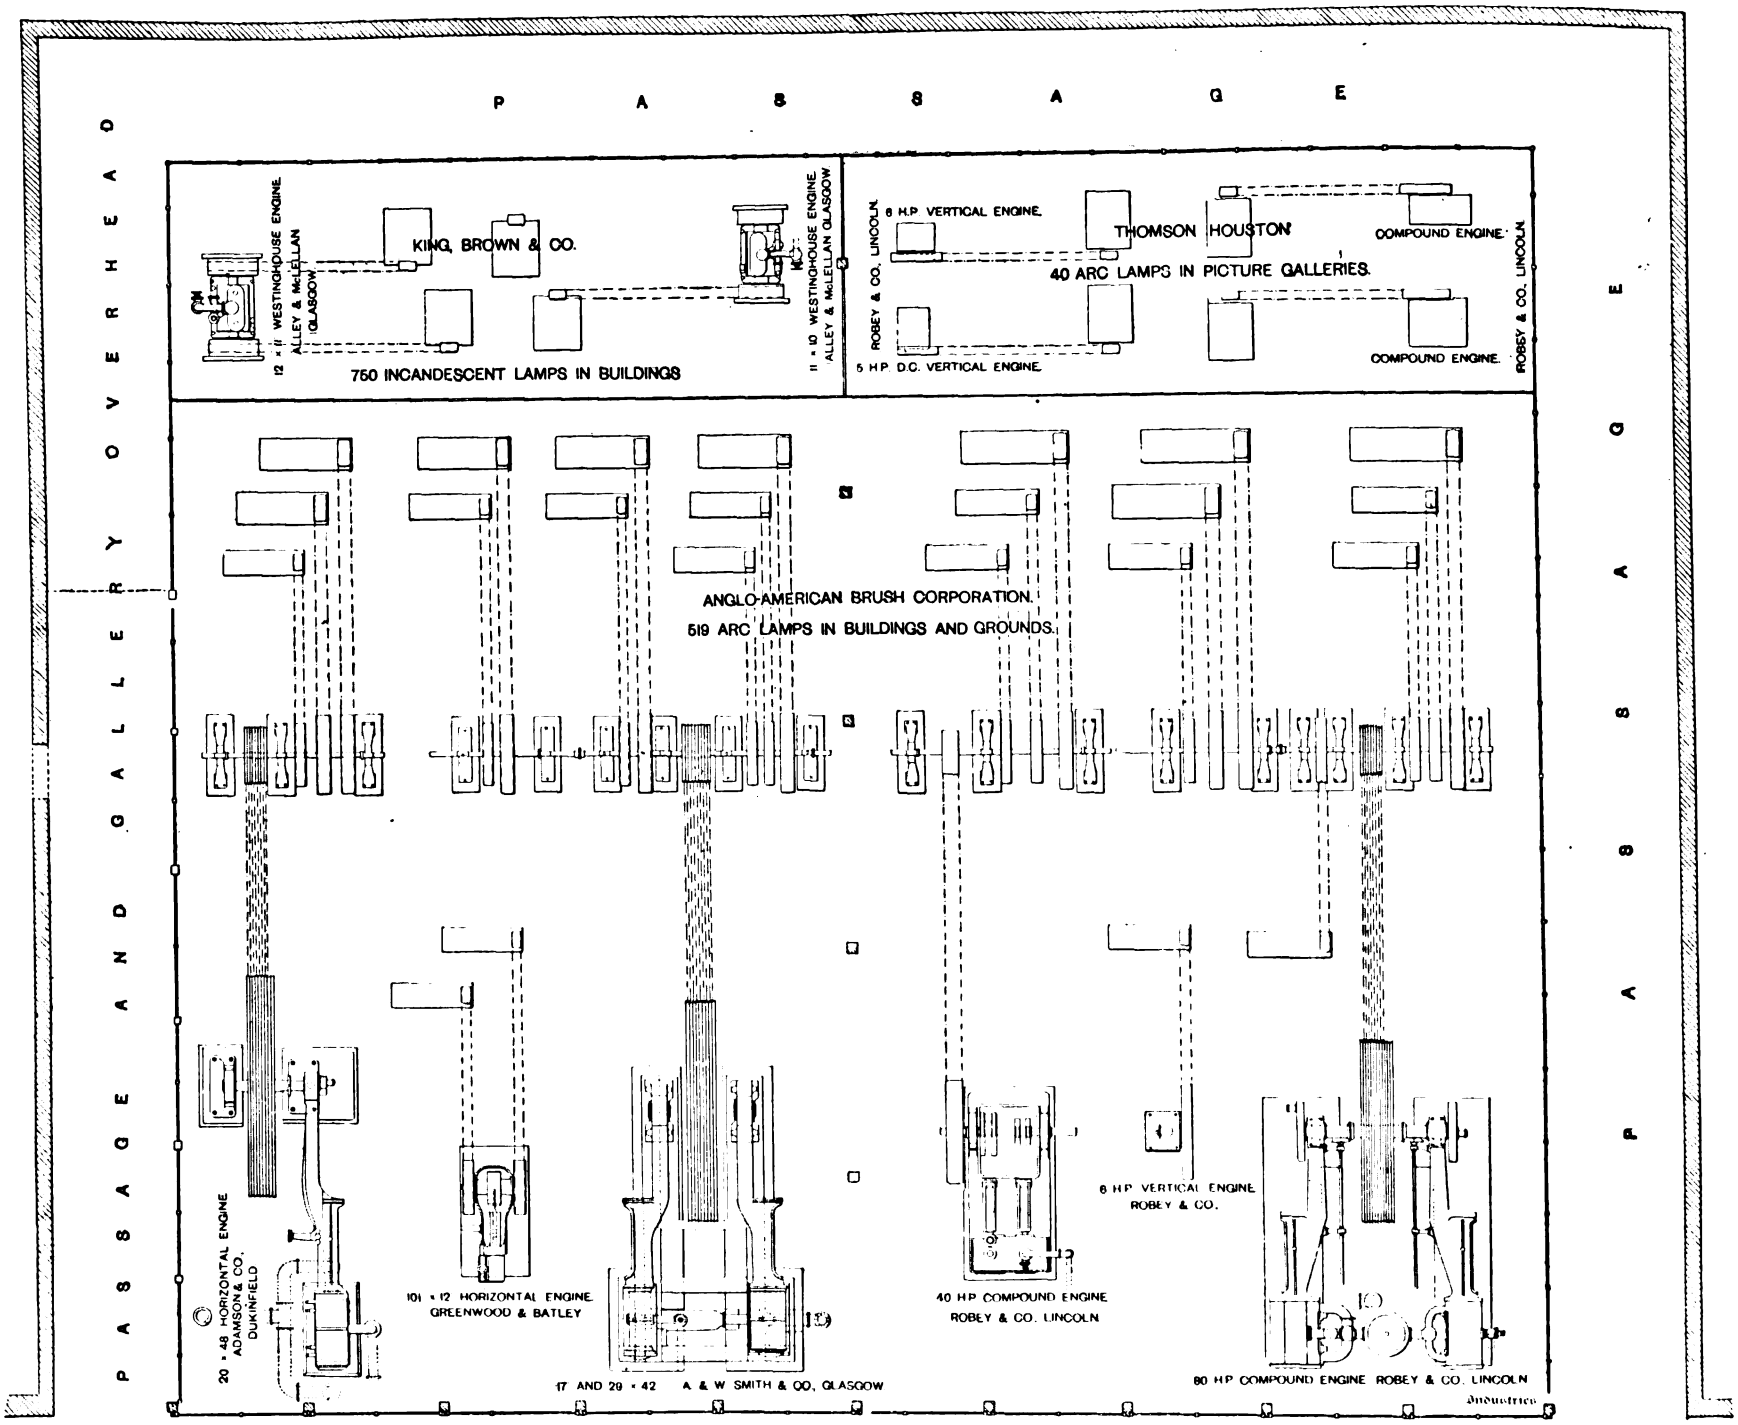
The Iron and Steel Markets.—The past week has not shown much improvement in the iron trade, either as regards the amount of business or prices. Considering the dulness, prices are remarkably firm, this being probably in a measure due to the very light stocks in hand. Only small lots are taken, buyers expecting after a while to be able to place their orders on better terms. There has been a moderately large business in pig iron, but there is no disposition to do more than to cover immediate requirements. This demand is sufficient to maintain prices for standard brands, and while a few lots of other descriptions have been placed either as sample lots or at prices low enough to make the buyer feel safe, it has been found to be impossible to make headway at the quoted rates. The low prices ruling for finished iron compel consumers to economise in every way, and as Western cities are getting pig iron at a cost of from $1 to $2·50 per ton less than Eastern cities, it is impossible to successfully compete for Western trade. Many of our Eastern manufactories have branches in the West, and the lower cost of pig iron is gradually moving the greater part of the business intended for Western trade to Chicago, St. Louis, St. Paul, and other cities. The demand for manufactured iron is disappointing. Prices, too, are unsteady, and without anything to indicate improvement in the near future. The chief object of manufacturers is to cheapen cost to meet competition from outside sources, but this cannot be done at present. There is a fair consumption, but not nearly equal to what it was a year ago, hence the continuous seeking for business. Prices are about 2·1 cents per lb. for plate iron, 1·85 cents to 1·9 cents for best bars, and 2·15 cents to 2·2 cents for angles. The steel rail market is quiet. Prices are well sustained, and mills are quite busy either on rails or steel for other purposes. The wrought iron tyre business has been improving, and a fair amount of business is being done. On large orders competition is very close, and concessions are very easy to obtain.

The Metal Markets.—The copper market has been rather quiet, and shows signs of declining prices. Tin has been active and declining. For spot 34½ cents per lb. is bid, and 36 cents asked. May sales are down to 29·50 cents. The business in lead is almost entirely confined to speculators. About 1000 tons have been dealt in. April prices are 5·15 cents per lb. Consumers have been buying very little, but as the season opens there will probably be a heavier demand.

Electric Transmission of Energy.—Wherever electricity has been introduced, motors are rapidly taking the place of small steam plants. In St. Louis, Mo., at present 125 h.p. are used; in Boston, over 400 h.p. One company in New York distributes 200 h.p. among sixty customers, and arrangements are now nearly completed for a plant of 2000 h.p. on the east side, and a similar plant on the west. Motors are supplied from ⅛ to 25 h.p., and are used, among other purposes, for cash railways in stores, sewing machines, ventilating fans, elevators, in foundries, printing offices, by tailors, and for street cars. The cost of power varies considerably. In Pittsburgh a half horse power motor is rented with power for £2 per month, and a 10 h.p. motor for £16. In Buffalo, N.Y., the rental of a half horse power motor and power is £1. 4s. per month.

PHILADELPHIA, 7th April, 1888.

The Harbour of Philadelphia.—A report has been published on the improvement of the port, and the total removal of two islands, and the partial removal of a third island in the Delaware. The scheme is considered quite practicable by the Board of Engineers appointed to consider the matter. About 400,000 cubic yards of material would have to be removed, the cost being estimated at from £600,000 to £800,000.



New Works.—A commencement has been made in replacing the wooden building of the Pennsylvania tube works by an iron building. The new building is to be built outside the old one, so as not to interfere with the working of the mill. It will be 260ft. wide by 363ft. long, and will cost about £20,000.

Open Hearth Steel Plant.—The Henderson Steel and Manufacturing Company, of Birmingham, Alabama, are putting down a 120-ton steel plant, which is of a somewhat novel design. The hearth is made of calcined dolomite, pulverised and mixed with 10 per cent. of fluorspar, charged loose into the furnace, where it is set by heat. The operation is divided into two parts, taking place in separate chambers, a purifying and a converting one. Into the first the molten iron is taken from the blast furnace and treated with ore to remove the silicon and half the carbon, which operation requires two and a half hours. To prepare the furnace for a second charge takes half an hour, allowing about seven heats for twenty-four hours. The metal is then transferred by an outside runner to the converting chamber, where two and a half hours longer are required to convert it into steel by removing the phosphorus and some more of the carbon. Half an hour is required to repair this chamber, using 80lb. of lime and fluorspar per ton of steel. Out of pig iron containing ·7 per cent. phosphorus, 1·0 per cent. silica, and 22 per cent. sulphur, steel has been made containing ·75 per cent. carbon, ·05 per cent. phosphorus, and ·099 per cent. of silica, and has been found excellent for tools and cutlery.

GLASGOW INTERNATIONAL EXHIBITION, 1888.

General Plan of Electric Lighting Plant.

ELECTRIC LIGHTING AT THE GLASGOW INTERNATIONAL EXHIBITION, 1888.

The combined electric lighting installations at the Glasgow International Exhibition afford a very fine display. The total number of arc lamps in the building and grounds is 559, and the number of incandescent lamps is 750. These numbers are exclusive of the powerful arc lamps used in the manipulation of the fairy fountains, which are supplied, with the other plant for this attractive feature, by Messrs. W. & J. Galloway & Sons, Manchester. The Anglo-American Brush Electric Light Corporation supplies 519 arc lamps. Messrs. Thomson, Houston, & Co., Limited, supply forty arc lamps, and the installation of incandescent lamps is by Messrs. King, Brown, & Co., of Edinburgh. The above illustration represents the plan of the dynamo room, and the arrangement of engines and dynamos. The room affords ample space, engines and machines being alike shown to advantage. The Anglo-American Brush plant occupies the most prominent position, their share of the work being the lighting of the main portion of the buildings and all the grounds. Messrs. King, Brown, and Co.'s incandescent lamps are fitted in the refreshment and dining rooms and in some of the smaller courts, while Messrs. Thomson, Houston, & Co. have their forty arc lamps placed in the picture galleries. The Anglo-American Brush Co. supply the current for their 519 arc lamps from nine large and ten smaller dynamos. The large dynamos supply current to thirty-five arc lamps and the smaller to twenty-five arc lamps each. Power for this portion of the installation is obtained from engines made by four separate firms. The largest set is by Messrs. Robey & Co., Lincoln, who supply a pair of horizontal compound engines working up to 240 i.h.p., a single engine working up to 120 h.p., and a vertical engine of 6 n.h.p. Messrs. A. & W. Smith & Co., Eglinton Engine Works, Glasgow, supply a horizontal compound engine with 17in. and 29in. cylinders, and 42in. stroke. Messrs. D. Adamson & Co., Dukinfield, Manchester, supply a large horizontal engine having a cylinder 20in. diam. and 48in. stroke, and Messrs. Greenwood & Batley, Leeds, exhibit a horizontal engine with cylinder 10½in. diam. and 12in. stroke. The main shafting in the dynamo room is divided into sections, and the large engines actuate separate sections of the shafting by means of rope gearing. The pulleys on this shaft, as also to a large extent throughout the mechanical section of the Exhibition, are the patent "differential tight-grip" pulleys of Messrs. Weyman & Johnson, of Guildford.

The installation of Messrs. King, Brown, & Co. consists of two Westinghouse engines, one having a cylinder 12in. diam. and 11in. stroke, and the other a cylinder 11in. diam. and 10in. stroke. The engines are made by Messrs. Alley & McLellan, and actuate by direct drive four dynamos of Messrs. King, Brown, & Co's. own manufacture. Messrs. Thomson, Houston, & Co's. installation consists of four dynamos, the power for which is derived from Messrs. Robey & Co's neat little vertical engines of 5 and 6 n.h.p. and their horizontal engine having cylinders 5½in. and 9in. diam. and 6in. stroke. The arrangements for the electric lighting of the Exhibition have been devised by and carried out under the superintendence of Mr. W. A. Bryson, engineer to the Exhibition. We hope to illustrate in an early number the plan of wiring, and shall then also give further details of this plant.

ENGLISH FISHERIES.

In a recent issue we supplemented the review of a Bill introduced into Parliament with the object of reducing rates of carriage on common kinds of fish, by a short account of the present state of our fishing industry, and a protest against the existing conditions under which its full development is retarded. A few days ago the whole matter was brought before Parliament by Sir E. Birkbeck in the following motion: "That in the opinion of this House the Fishery Department of the Board of Trade, as now constituted, is not in accordance with the scheme by which the control of the fisheries was transferred to the Board of Trade; and in order to carry out that scheme, and to secure the proper management and

Digitized by Google

development of the Fisheries of England and Wales, they should be placed under an authority comprising, in addition to the officials of the Board of Trade, persons with a practical knowledge of the sea and inland fisheries." He recommended the appointment of elective councils at all the principal fishing ports on the coast, with certain powers for the regulation of local fisheries, and to send representatives periodically to London to confer with a central board. As illustrative of the point to which in our previous article we directed attention, as to the heavy carriage rates now charged on fish, and the necessity for bringing English merchants and consumers into closer relations, Mr. Mundella stated that when he was staying on the Malaga Pass in Switzerland, he found English turbot, landed at Ostend, was selling cheaper there than at the West End of London. Sir M. Hicks-Beach, on behalf of the Government, while claiming that the Fishery Department of the Board of Trade was in much closer touch than formerly with the fishing industry, admitted that there was still great scope for improvement in respect to local regulations and by-laws, the collection of statistics and investigations by scientific experts. The motion was finally withdrawn, on the understanding that a Bill would shortly be introduced to meet the exigencies of the case, and embodying the incorporation of local councils. The importance of this industry, alike to the quarter of a million of men engaged in it, and the whole body of consumers, is sufficient justification for urging upon the Government the necessity for initiating the basis of a satisfactory *régime* under which the full resources of our fisheries may be cultivated, and for encouraging the better distribution of their product.

The *Times* St. Petersburg correspondent states that the death is announced of the celebrated "naphtha king," Ludwig Nobel, who has created such a gigantic petroleum industry at Baku. He was one of the three Swedish brothers whose enterprising and wonderfully successful careers in Russia are now known to all the world.

Steam Engines and Boilers.—The Steam Engines and Boilers Bill, intended to provide for the registration and certification of steam engine and boiler attendants, of which we gave an abstract in our issue of the 30th March, was rejected on the 17th inst., when brought in for second reading, by 147 to 96. It was pointed out that no proof whatever had been given that explosions would be prevented by the passing of such a measure. Sir M. Hicks-Beach observed that it would not deal with carelessness or negligence generally; and further, that it would interfere with small trades and agricultural operations.

University College, Bristol.—This College will re-open on the 25th inst. The work in the engineering department during the coming term will be largely of a special character. Professor Ryan will lecture on civil engineering, mining engineering, and electrical engineering. The last named course will comprise electric lighting, dynamo-electric machinery, and transmission of power. It is arranged for civil engineering students to attend Professor Lloyd Morgan's practical geology classes in the field, and Mr. Selman's outdoor exercises in surveying. Electrical engineering students and others will occupy themselves in the chemical, physical, and engineering laboratories of the college.

Death of Mr. Matthew Arnold.—England has lost one of her celebrated sons by the death of Mr. Matthew Arnold, which took place on Sunday, the 15th inst. Mr. Arnold came of a distinguished family, being the son of Dr. Arnold, the late head master of Rugby, and brother of Sir Edwin Arnold, the author of the "Light of Asia." He was a poet and essayist of eminent ability, and for ten years he occupied the Chair of Poetry at the University of Oxford. The most lasting result of his life's work, however, will be understood by the fact that, for nearly twenty years, he was the chief adviser of the Government on the subject of education. In 1851 he was appointed to be an Inspector of Schools; and it was not until 1886 that he retired from the chief inspectorship. In 1859-60, he was sent as a foreign commissioner to inquire into the state of popular education, and to obtain information respecting the various plans of education adopted by several Continental States. Mr. Arnold again visited the Continent in 1865, to procure for the Royal Commission on middle class education information about foreign schools.

Steam Boiler Explosions.—The usual fortnightly meeting of the Liverpool Engineering Society was held at the Royal Institution, Colquitt-street, on the 11th inst., Mr. Charles H. Darbishire, Assoc.M.Inst.C.E., president, in the chair, when a paper on "Steam Boiler Explosions" was read by Mr. John J. Webster, M.Inst.C.E., and discussed by the members. The paper commenced by stating that the average number of steam boiler explosions during the last twenty-five years was about fifty-six per annum, the average loss of life amounting to about seventy per annum, and although the number of explosions was very great, and the loss of life to be deplored, the actual percentage of explosions to boilers at work was very small, being at the rate of one explosion to every 2500 boilers at work. Owing to the good work done by the different boiler associations, and to the immense improvement in the design and construction of boilers, this percentage had now been reduced to less than one in 6000. The paper then described in detail the various causes of boiler explosions under the following heads: (1) Bad material; (2) defective design, including the mountings and fittings; (3) bad workmanship; (4) careless and improper working; (5) neglect of periodical inspection; (6) bad maintenance. The paper then described some interesting physical phenomena, which had given rise to a novel theory of boiler explosions, and after discussing the question of simultaneous boiler explosions, concluded with a brief review of the existing and proposed legislation on the subject. The paper was illustrated by numerous wall diagrams. As several members desired to take part in the debate the discussion was adjourned.

Notices of Meetings.

THIS WEEK.

Institution of Civil Engineers.—Friday, 20th April, 7-30 p.m. Students' meeting. Paper to be read on "The Speed Trials of the Latest Addition to 'The Admiral' Class of British War Vessels," by Mr. David S. Capper, M.A., Stud.Inst.C.E.

Royal United Service Institution.—Friday, 20th April, 3 p.m. Paper to be read on "The Game of Naval Blockade," by Lieutenant H. Chamberlain.

Balloon Society of Great Britain.—Friday, 20th April, 8 p.m. Lecture on "The Architects', Engineers', and Surveyors' Bill, 1888," by Hugh Roumieu Gough, F.R.I.B.A.

NEXT WEEK.

Society of Arts.—Monday, 23rd April, 8 p.m. Cantor lecture on "Milk Supply, and Butter and Cheese Making," by Mr. Richard Bannister.—Tuesday, 24th April, 8 p.m. Applied Art Section. Paper to be read on "Craftsman and Manufacturer," by Mr. Lewis Foreman Day.—Wednesday, 25th April, 8 p.m. Ordinary meeting. Paper to be read on "The Physical Culture of Women," by Miss Chreiman.

Royal Institute of British Architects.—Monday, 23rd April. Ordinary meeting. Paper and discussion. Issue of balloting paper for the new Council.

Institution of Civil Engineers.—Tuesday, 24th April, 8 p.m. Ordinary meeting. Paper to be read, with a view to discussion, on "The Distribution of Hydraulic Power in London," by Mr. E. B. Ellington, M.Inst.C.E.

Civil and Mechanical Engineers' Society.—Wednesday, 25th April, 7 p.m. Paper to be read on "Railways for Rural and Undeveloped Districts," by Mr. James B. Walton, M.Inst.C.E.

Liverpool Engineering Society.—Wednesday, 25th April, 8 p.m. Ordinary meeting. Adjourned discussion on Mr. Webster's paper on "Steam Boiler Explosions." Paper to be read on "Air Brakes," by Mr. C. F. Bamford.

Society of Telegraph Engineers and Electricians.—Thursday, 26th April, 8 p.m. Paper to be read on "The Risks of Fire Incidental to Electric Lighting," by Mr. W. H. Preece, F.R.S.

Royal Institution of Great Britain.—Thursday, 26th April, 3 p.m. Lecture on "The Chemical Arts," by Professor Dewar.—Friday, 27th April, 9 p.m. Lecture on "Electrical Influence Machines," by Mr. J. Wimshurst.

PRICES CURRENT, 19th April.

Quotations at per ton, unless otherwise specified.

" English Ingots	152	0	0	"	153	0	0

Messrs. Carrick & Brockbank, Manchester, report as follows:—

Copper.—Since our last, quotations for Chili spot parcels have been firm at £80 to £80. 7s. 6d. per ton; but forward deliveries have fallen during the past few days to £77. 7s. 6d. three months. The stocks of raw copper continue to increase very rapidly, and the production in America and elsewhere is being largely augmented, so that the quantity of raw copper to be dealt with in stock and for early delivery is becoming serious. The syndicate has included nearly all the large producers of copper in its speculative arrangement, and most of the English smelters and manufacturers are also under contract for their supplies under this colossal monopoly. The consumers, however, hold aloof the world over, and the copper trade is still stagnant, stocks increasing accordingly. The position is thus without precedent, and all sides are waiting, and speculating on the ultimate result. Manufactured unchanged, and with very little demand.

Tin.—A moderate business is still being done in sharp cash Straits at £166 to £166. 2s. 6d.; forward deliveries are, however, quoted down to £115 per ton, according to date, but not much doing thereat, as consumers do not appear to have confidence, and are only buying for their immediate requirements.

Lead.—Quotations for Spanish have been variable during the past week, from £13. 12s. 6d. to £14 per ton.

Spelter rather lower again.

IRISH EXHIBITION IN LONDON.

At the Irish Exhibition, which is to be opened early in June, at the Olympia, Kensington, and which is intended to place before the English public the leading industries of Ireland, the exhibits will be classified as follows: Agriculture, textiles and manufactures, shipbuilding and sea industries, machinery and engineering, mining and mineral products, brewing and distilling; paper, printing, bookbinding, &c.; scientific, chemical, and allied industries; education and science, furniture and decoration, women's and cottage industries, fine arts, historical and antiquarian exhibits.

Digitized by Google

HOME INDUSTRIES.

MANCHESTER, 19th April, 1888.

The Engineering Trades.—Stationary engine builders are still fairly supplied with work, and in some cases are even fully occupied; but in many instances a good deal more business could be accepted if favourable terms were offered. Millwrights are well employed, and it appears probable that, for some time to come, this favourable condition of things will be maintained. Boiler makers continue to do a large business. Locomotive builders are finding a little more inquiry, and, on the whole, this branch of engineering is gradually recovering from the extreme depression of the past few months. The railway carriage and waggon builders are mostly well employed on contracts, and are not likely to be in any immediate want of work. Machine tool makers are booking orders much more freely than they were a short time ago, and inquiries are more numerous than they were. We understand that Messrs. Kendall & Gent, Victoria Works, Salford, have purchased the good-will, patterns, drawings, &c., in connection with the old established works recently occupied by Messrs. William Collier & Co., Salford. Wood working machinists are only indifferently employed, and the same remark applies to general iron founders. Makers of cotton machinery have sufficient orders on hand to employ them for long periods ahead. In spinning machinery there is an abundance of orders, particularly for carding engines and ring spinning machines. Several orders for carding engines on American account have been placed lately, and ring spinning machines are being largely sent to India. The figures recently given in a consular report from Tokio with relation to the advance of cotton spinning in Japan have attracted a good deal of attention. Looms and weaving machinery are still in good request, and although orders are not being given so freely as they were two years ago, there are still plenty to be found. In the miscellaneous class of engineering industries there are complaints made, both as to the scarcity of orders and the prices obtainable. The dispute between the engineers of the district and the moulders still continues, although there are one or two cases in which the desired advance has been granted. The dispute also exists in Oldham, and it is on the whole likely that an advance will be given, unless the present feeling of the majority of the outside employers alters. Our readers will remember that a few months since there was a long strike at Bolton for an advance of 2s. per week, which ended in the defeat of the men. The employers in that district have now decided to grant an advance, beginning on the first pay day in July, which will bring up the wages to the level of 1885. It is expressly stated that the advance is given in consequence of the receipt of more orders, although there is the usual complaint about prices not being remunerative.

Cotton Trade Wages.—Last week we referred to the fact that a demand had been made by the operatives in the Oldham district for advances in the rate of wages paid. In consequence of this a joint conference of representatives of the employers and employed was held, which has ended in a refusal on the part of the former to grant the advance. On their behalf it was contended that the working of eighty-seven spinning companies during 1885 resulted in an aggregate loss of £2,730, and that in 1886 the loss of ninety concerns was £61,000. The gain in 1887, which was a more profitable year, was only on share capital 2¾ per cent., and on loan and share capital combined less than 3½ per cent., the capital involved being £6,250,000. For an average of eleven years it was stated that the return was only 2½ per cent. on the share capital. The replies of the operatives to this statement show a curious notion of the position, as they contend they have nothing to do with losses, and that they should not suffer because capital is unremuneratively employed. It was suggested that a further conference should be held in January, 1889, and that in the meantime the matter should be in abeyance. At a subsequent meeting of the operatives resolutions were passed, which, if carried into effect, can only result in a strike.

A New Company.—The prospectus is issued of a company which has been formed to acquire the patent rights of machines invented by Count P. A. Sparre for the manufacture of cards used in the process of jacquard weaving, and also a special mode of making cartridges and other articles. The former part of the business is to be carried on in Manchester, under the superintendence of Mr. Jacob Lloyd, who has long been engaged in this work.

LONDON, 19th April, 1888.

The Money Market.—The value of loanable capital was considerably enhanced at the close of last week, both from a contraction of the supply and an increase of the demand. The Stock Exchange settlement of course absorbed a fair share, and a number of loans were repayable at the Bank. Borrowers are always desirous to transfer their obligations from the bank to the open market, and hence there was a distinct improvement in the price of money; but since then it has declined into pretty much the old groove, though rates are harder than they have been for some time. The Stock Markets were also much brisker at the end of the week. There was an altogether buoyant feeling, and prices gained all round. The Stock Exchange was in the humour for business and, curiously enough, this was evidenced by a distinct fall in the price of preference securities. The jobbers had not expected the fund holders to assent unanimously to Mr. Goschen's conversion proposals, and so they carefully bought up every preference security they could lay hands on, and put them up to prices which would produce just a trifle over the 2¾ per cent. at which the Chancellor of the Exchequer assessed the credit of the country. The fund holders having preferred to stick to Consols with a quarter per cent. taken off, jobbers have been left with great quantities of securities on their hands, which are unsaleable at the high prices put upon them. They have, therefore, been reluctantly compelled to allow the official prices to drop, so as to get rid of them at all. Thus this fall in fine securities was really a sign of a healthy business tone in the market. Unfortunately, Monday brought disquieting news from Paris, which gave a blow to the markets, and later on the hopeless appearance of the telegrams from Charlottenburg completed the discomfiture, everything falling, and business coming to absolute stagnation. But recovery sets in speedily, and as the market is really healthy, the lost ground should be more than recovered. The hurry to register new companies continues, as may be seen from the list in the next paragraph, and which is merely a selection of the more important projects.

Companies.—Since our last report the following new companies have been registered: The British Sodium and Aluminium Company, Limited, with a capital of £1,050,000, to acquire the inventions of Mr. Albert Berwick Cunningham for the manufacture of sodium and aluminium, the right to an exclusive supply of artificial cryolite, and to manufacture and sell sodium and potassium, or utilise the same for the purpose of reducing any metal from its compounds, and chiefly aluminium; E. Green & Son, Limited, with a capital of £130,000, to acquire the business of manufacturer of fuel economisers and steam generators, now carried on by Sir Edward Green, Wakefield; Mineral Oil Extraction Company, Limited (Rose's patent), with a capital of £200,000; The Butterley Company, Limited, with a capital of £600,000, for the acquisition of the undertaking of the Butterley Company, Alfreton, Derbyshire; Dowson, Taylor, & Co., Limited, with a capital of £100,000, to acquire the business of Messrs. Dowson & Taylor, fire engineers, Bolton, including the benefit of a trading agreement with Messrs. Mather & Platt, Salford; Grenoble St. Etienne Breweries Company, Limited, with a capital of £200,000; Chesters Brewery Company, Limited, with a capital of £300,000, to acquire the brewing business carried on at Ardwick, Manchester, under the style of Executors of the late Thomas Chesters; Edward Marston & Co., Limited, with a capital of £20,000, to purchase a patent for an improved willow peeler, and carry on the business of cane splitting, cutting and weaving, &c.; the Mid-Kent Water Company, Limited, with a capital of £18,000; Port Royal Docks and Harbour Board, Limited, with a capital of £500,000, to acquire and develop the port of Port Royal, South Carolina; Public and Private Works Company, Limited, with a capital of £200,000; British Borneo Guano Company, Limited, with a capital of £100,000; the General and Domestic Inventions Company, Limited, with a capital of £60,000; the West Clogan Gold Company, Limited (Wales), with a capital of £15,000; Transvaal Komati Gold Mining Company, Limited, with a capital of £50,000; Lower Weardale Minerals Company, Limited, with a capital of £50,000, to carry on mining operations, &c., in Durham; the Iron Crown Gold Mines, Limited (Hungary), with a capital of £230,000; Sicilian United Copper Mines, Limited, with a capital of £100,000; New Bultfontein Mining Company, Limited, with a capital of £935,000; California Water and Land Company, Limited, with a capital of £150,000; Cleator Glebe Mining Company, Limited, with a capital of £60,000, to acquire iron ore mines in Cumberland; Sorbridge Tin Mining Company, Limited (Devon), with a capital of £50,000; Descada, Cobalt, and Copper Mines of Spain, Limited, with a capital of £20,000; the Kuysna Concession Gold Mining Company, Limited (Cape Colony), with a capital of £100,000; Sheba Reef Gold Mining Company, Limited (South Africa), with a capital of £60,000; Atlas (Broken Hill) Silver Lead Mining Syndicate, Limited, with a capital of £300,000; the Tilt Cove Copper Company, Limited (Newfoundland), with a capital of £160,000; Original Pittsburg (Grass Valley) Gold Mines, Limited, with a capital of £100,000; the Oberlin Tin Mining Company, Limited (Queensland), with a capital of £200,000; and the Golden Fleece, Limited (Victoria), with a capital of £100,000.

Hemp.—There is but little doing in Baltic hemp, but business in Manilla hemp for arrival has been brisk.

Sugar.—Although buyers are cautious, the situation shows signs of improvement, and sellers have more confidence in the future, especially as the imports of raw and refined beetroot sugar have decreased, and an improved demand for home refined may therefore be anticipated. The Sugar Bounties Conference has been holding further meetings during the present week.

Electric Lighting in Kensington.—The Board of Trade has consented to receive a deputation from the Kensington Vestry to-day, several questions of importance having arisen with regard to the proposal of the parish authorities of Kensington to carry out electric lighting themselves. Mr. John Braye, of the Kensington Vestry, contends that the Vestry already possesses the right to become a trader, and amongst other undertakings to supply electricity to private consumers. As a matter of fact, under an existing Act, London vestries have the power to raise money for lighting purposes, and as the Act in question does not define the character of the lighting, a section of the Vestry is inclined to interpret the Act as being applicable to electric lighting, and this question among others is to be discussed between the deputation and the Board of Trade.

Electric Lighting Act (1882) Amendment Bill.—At a meeting of traders and others interested in the subject of electric lighting, which was held recently at the offices of the Anglo-American Brush Corporation, it was decided to petition in favour of Lord Thurlow's Bill, which is now before the House of Lords. The subscribers to the petition which is now being signed, express the opinion that the extension from twenty-one to forty-two years of the period stipulated by the Act of 1882, after the expiration of which local authorities may have the option of purchasing electric lighting undertakings within their district, will lessen the restrictions which have hitherto prevented the electric lighting industry from making great progress. They recommend, therefore, that the Electric Lighting Act of 1882 Amendment (No. 2) Bill, which has also been introduced in the House of Lords, and which would raise complex questions in connection with the powers of local authorities, should not be proceeded with if found to have a tendency to delay the first Bill, which ought to be passed as soon as possible.

Railways.—The gross receipts of the twenty-three principal railways in the United Kingdom for the week ending 8th April amounted to £1,176,577 on 15,850¾ miles, as compared with £1,219,547 in the corresponding period of 1887, when the mileage was 15,708¾ miles. An increase is thus shown in the mileage of 142 miles, or 0·9 per cent., and a decrease in the receipts of £42,970, or 3·5 per cent.

The Jubilee Shot.—This shot was fired at Shoeburyness last Monday. Particulars respecting the estimated trajectory were given in a note in our issue of 16th March.

Taylor's Engraving Machine.—In connection with the illustrated description which we gave of this machine in our last week's issue, we are asked to state that it is made by Messrs. T. S. & W. Taylor, engineers, Slate-street, Leicester. As stated in our description, the London agents for Messrs. Taylor & Co. are the Britannia Company, 100, Houndsditch.

Institution of Mechanical Engineers.—The ordinary general meeting of the Institution of Mechanical Engineers is arranged to be held on Thursday and Friday, the 3rd and 4th prox., at the Institution of Civil Engineers, 25, Great George-street, Westminster. The following papers will be read and discussed at the meeting as far as time will permit: (1) Third Report of the Research Committee on Friction Experiments on the Friction of a Collar Bearing; (2) Description of the Emery Testing Machine, by Mr. Henry R. Towne, of Stamford, Connecticut, U.S.A.; (3) Supplementary Paper on the Use of Petroleum Refuse as Fuel in Locomotive Engines, by Mr. Thomas Urquhart, locomotive superintendent, Grazi and Tsaritsim Railway, South East Russia. The anniversary dinner will be held on Friday evening, the 4th prox., at the Criterion, Piccadilly. The Marquis of Hartington has accepted the invitation to be present at the dinner, and it is hoped that a large number of members will be able to be present on the occasion.

GLASGOW, 19th April, 1888.

Glasgow International Exhibition.—Though Saturday was nominally the last day for the reception of exhibits, it was found quite impossible to take delivery of the enormous number of cases which arrived at the last moment. The week, indeed, had well advanced before the last consignments could be taken from the railway stations and deposited in the halls of the Exhibition. It is now possible to estimate more fairly than a few days ago the probable appearance of the various sections. The large trophies of the Steel Company of Scotland and of Messrs. Colville remind the visitor immediately on entering the machinery section, that he is in one of the chief centres of the steel industry; while in general machinery there is variety enough to be instructive as well as interesting from a commercial point of view. Much has yet to be done to make the Exhibition presentable to the general public, but the labour of many thousand hands can in three weeks effect wonderful transformations, so that there is little likelihood of any material deficiency on the opening day, the 8th May.

Heating of Railway Carriages by Gas.—Experiments have been in progress of heating railway carriages by gas. The method adopted is the invention of Mr. Foulis, gas engineer to the Corporation of Glasgow. The feature of the invention is the placing of a small boiler above the lamp, which is fixed in the usual way in the roof of the compartment. The water in this boiler is made to circulate by means of an arrangement of valves through pipes, placed under the seats. The experiments have been carried out in carriages belonging to the Glasgow and South-Western Railway.

Iron Market.—In spite of a fair amount of shipments during the week, the pig iron market has shown little buoyancy. The tone has been firm, but has probably been prevented from assuming an upward tendency by the want of encouraging reports from America. Steel makers are busy with boiler plates, and with the completion of the contracts for ship plates booked some months ago.

THE CLYDE TRUST.—A reunion of the employés of this Trust was held on the 6th inst. in the Waterloo Rooms, Glasgow, under the presidency of Mr. George W. Clark. After tea had been provided, a short address was delivered by the chairman, in which he pointed out that 130 years ago the Clyde Trust did not employ a dozen men, whereas now they had about 1000 men in their service. After this address, Mr. James Deas, jun., was presented by his fellow employés with several valuable articles in consequence of his leaving the service of the Clyde Trust to join the engineering staff of the Manchester Ship Canal.

(From our own Correspondents.)

LIVERPOOL, 18TH APRIL, 1888.

THE ISLE OF MAN TRAFFIC.—It is most probable that the competition for the traffic of the coming season will be between the old company and the Manx Line only; the "Lancashire Witch," the screw steamer belonging to one of the competing companies last year, being advertised for sale by auction. Two of the old company's largest boats are being lengthened and fitted with a promenade deck the whole length of the vessel; the old machinery has also been taken out and replaced with triple expansion engines and steel boilers. It is expected by the builders that the speed will be greatly increased, and that they will be able to compete satisfactorily with the steamers of the Manx Line. It is reported that the latter company are obtaining two additional steamers, and they expect to commence running early in May. There was a rumour that the competing companies had come to some arrangement whereby the regular fares would be maintained; this, however, has been dispelled by the advertisement of the old company, stating that on and after the 1st of May the return fares will be reduced to 5s. cabin and 2s. 6d. steerage.

THE EMIGRATION SEASON.—The emigration season has now fairly commenced, and, as Liverpool appears to be the favourite port for the departure of emigrants of all nations, long streams of men are daily to be seen wending their way to the landing stage. Last week was an exceptionally busy time, all the Atlantic liners sailing with their full complement of passengers; the total number of emigrants was greater last week than was ever known in any previous week.

SHEFFIELD, 18TH APRIL, 1888.

THE HEAVY INDUSTRIES.—The condition of the heavy industries continues to be satisfactory, though the exports of unwrought steel from the town, particularly to the United States, have not been so extensive as in the first quarter of last year. However, the bulk of heavy material now being sent out of Sheffield is probably greater than at any time in its history. In railway material the demand has grown very rapidly, and rails, tyres, and axles are being turned out in immense quantities both for home and foreign markets. The rail mills, not only in the town, but those which are worked at Rotherham, Penistone, and Workington, with Sheffield capital, are all doing an extensive trade. One of the best foreign customers is the Argentine Republic, but Japan is perhaps the country in which industrial and commercial enterprise is most active. In March, last year, the latter country imported railway material from England to the amount of £5,612; last month it spent no less than £58,303. In addition to railway material, Japan is taking from Sheffield a quantity of heavy machinery. The engineers and boiler makers are doing a profitable business, and firms engaged on big castings and shipbuilding material continue to be well employed. There is great activity at Messrs. T. Vickers & Sons, Messrs. W. Jessop & Sons, and the Hadfield Steel Foundry Company. The success of the projectiles manufactured by Messrs. T. Firth & Sons in the recent tests has caused great satisfaction. It is now proved that Sheffield compound armour plates and shells cannot be beaten by foreign makers. Ship armour, however, is not yet at its best, and one or two Sheffield firms are exercising their best powers to obtain still greater excellence. The balance of practical and scientific opinion is in favour of steel faced plates, and it is to the improvement of these that attention is turned.

LEEDS, 18TH APRIL, 1888.

IRON AND STEEL.—The manufactured iron trade is brisker, and in all classes of steel there is more doing. Billets are bought up with greater eagerness and beyond present wants, the feeling being that prices may go higher. The well known local firms, such as Kitson's, Tannett's, and Whitworth's, are exceedingly busy, the last mentioned on Government orders. Heavy machinery, colliery plant, roofing, bridge work, are all in better demand, and at the foundries work is plentiful. Leeds is profitably participating in railway development trade. It is sending out a vast quantity of railway material; and it is also much busier than it was on textile machinery and mill fittings. The textile industries continue steadily to improve, and necessitate extensions, new plant, and renewals. Messrs. Kitson have extensive orders on hand for locomotives, and are doing more in steam tram engines. Generally the heavy trades of Leeds are in a prosperous condition, and makers who are turning their attention to entirely new markets find that their trouble is not thrown away.

NORTH STAFFORDSHIRE, 18TH APRIL, 1888.

THE IRON TRADE.—Work has now been generally resumed throughout the district, and specifications are coming in freely. The results of the quarterly meetings were not encouraging to producers, either with regard to price or bulk of orders, and the outlook for the immediate future is an indifferent one. It will soon be possible to head this paragraph, "The iron and steel trades," as it is anticipated that within a few weeks the latter metal will be produced in this district, at the new works of the Shelton Iron and Steel Company. There is no alteration in the price of pig iron, forge quality being worth from 34s. to 36s. at works according to brand, and foundry iron fetching about 40s. for No. 1 and 1s. 6d. less for No. 3.

NORTH STAFFORDSHIRE MINING INSTITUTE.—An ordinary meeting of this Institute was held at Stoke on Monday last, the chair being taken by Mr. J. Lucas, vice-president. Mr. J. W. Swan read a paper on "Edison-Swan's (Electric) Miner's Safety Lamp." The lamp, several samples of which were exhibited on the table, consists of an incandescent lamp in connection with a portable generator of electricity, and gives more than double the light of an ordinary oil lamp. Its weight is rather over 5lb., but it can be hung up at the working face. After the original outlay the cost of maintenance, &c., amounts to only 5d. per week per lamp, in cases where several hundreds are in use. A protracted discussion proved the interest taken by members in the application of electricity to the lighting of mines, and Mr. Swan's lamp was looked upon as a very considerable development on all previous efforts in this direction. Pearson's patent safety lamp for detecting the presence of gas, and containing an automatic appliance to extinguish the flame in case of an inrush of explosive mixture, was also exhibited and explained.

SOUTH WALES, 18TH APRIL, 1888.

TIN PLATES.—It is a remarkable fact that notwithstanding the present high price of tin, which remains at £166, tin plates are at the same level as when the metal was at £102. It is not surprising, therefore, that a paragraph should be going the round of the Press cautioning users against plates in the coating of which lead has partially been employed. The poisonous nature of such a mixture is too well known to suppose that any maker having a reputation to lose would resort to the practice. The extent of the use of canned fruit in the United States is so great that it is there being urged that an inspector of tin plates should be appointed at once. In the meantime the extraordinary character of the phenomenon is intensified by the circumstance that stocks are 50,000 boxes less than the corresponding week last year. A further attempt to form a syndicate to raise prices has again failed for want of the necessary combined action on the part of makers.

PAVING.—A new pavement has just been completed in Caroline-street, Cardiff, by the French Asphalt Company, which will be watched with some interest. Upon a foundation of cement concrete, 6in. thick, a layer of compressed asphalt of French origin is well rammed with heated iron rammers. The asphalt is first ground to a fine powder and roasted. After the process of ramming, the asphalt becomes of the same consistency as the natural rock, and makes a road suitable for the heaviest traffic; the cost of maintenance and cleaning is very small, averaging 7d. or 8d. per yard per annum, as against about 2s. for macadam.

BARROW-IN-FURNESS, 18TH APRIL, 1888.

IRON AND STEEL.—The steady tone of the hematite pig iron trade still continues. There is a good market for all classes of pig iron; but Bessemer is more especially in brisk request, owing to the large consumption on the part of steel makers. There is not a large trade being done in the forge and foundry departments. Orders are offering more freely on general foreign account, and a better trade is being done with America than was expected a short time ago. Prices of pig iron are unchanged at about 44s. per ton net f.o.b. for parcels of Bessemer iron in mixed numbers, and 43s. for forge and foundry, No. 3 quality. Stocks are still very large, especially at some of the works; but at Barrow they are represented almost wholly by the parcels held by merchants or speculators. The make of iron is fairly maintained, although all the furnaces are not in blast. Thirteen out of fourteen furnaces in Barrow are in blast, and the fourteenth is undergoing repairs. Fully 90 per cent. of the pig iron made in Barrow is converted into steel at the local works. The steel trade is exceptionally busy in all departments, and there is much activity both in rails and in Siemens-Martin steel. Rails have been very largely ordered, and the mills are briskly employed night and day. Prices are steady, at from £3. 18s. 6d. to £4 for heavy sections. Light sections are quoted 5s. over these prices.

MIDDLESBROUGH, 18TH APRIL, 1888.

PIG IRON.—This market has been keeping very firm for some time past. No. 3 has been offered at 31s. 9d., although 31s. 10½d. to 32s. had ruled for some time past. It is believed that this temporary depression will give place to a further strengthening of the market as the season advances and the northern ports are opened out. The shipments continue to improve; the total for the current month up till Monday, the 16th April inclusive, amounting to 45,808 tons, against 34,035 tons to same date last month. Germany and Holland have more than doubled their take. There is a falling off in the shipments to Scotland; but that is not to be wondered at, considering the state of the Scotch market.

MANUFACTURED IRON AND STEEL.—The works are going steadily on old orders, but manufacturers are becoming anxious about the future. Buyers are holding off, in the expectation that prices will fall. In finished steel much the same sort of feeling exists. Heavy rails are taken lower than ever, £3. 12s. 6d. per ton having been accepted.

COAL AND COKE.—The coal industry maintains its activity. The land sale will soon be declining, but this will be replaced by exports to the northern ports as they become open. Coke is steady, and maintains its price.

SUNDERLAND, 18TH APRIL, 1888.

SHIPPING TRADE.—The last week's coal exports were scarcely up to the average, although, as compared with the previous week, there was a marked improvement. Altogether 78,408 tons were shipped, an increase of 23,443 tons on the seven days preceding; 57,779 tons went coastwise, and 20,629 to foreign ports. Other shipments comprised 1840 tons of patent fuel, 400 tons of coke, 24,000 dozen bottles, 105 tons of cement, 18 tons of fire bricks, whitening, and goods. The import trade was very brisk, especially in esparto grass, iron ore, timber, block ice, and silver sand. There were also eleven coasting cargoes of various merchandise received.

LIFE SAVING RAFT.—Mr. John A. Baharie, of this town, has invented a novel life saving raft, capable of supporting ten or twelve persons. It is composed of very light materials, and folds up into a small compass, so that it requires a minimum stowage space, and can always be kept at hand ready for immediate use. It is self opening, spreading to its full extent immediately it touches the water; it should prove of special value in excursion and other passenger steamers, where sufficient boat accommodation is really impracticable.

NEWCASTLE, 18TH APRIL, 1888.

CHEMICALS.—In some branches of chemical industry greater animation has been manifested during the past two weeks, and this circumstance tends to encourage the hope that a healthier tone will soon be imparted to the trade generally. The demand for bleaching powder and soda crystals has very sensibly increased, and the supply of high strength caustic soda is far from being sufficient to meet the requirements of the market. Messrs. Allhusen and Co. have now a large force of operatives engaged in the erection of new premises for the manufacture of the last named product, and before the close of the year they will be in a position to more than double their present output. The Jarrow Chemical Company have commenced preparations for the working of a new process referred to in a former report. The Heworth Alkali Works are now extremely busy, and another chemical factory in the vicinity of Felling has re-commenced operations after a somewhat lengthened stoppage. The extensive works of Messrs. H. L. Patterson & Co., and also the works of Messrs. Boult & Partners, are still inoperative. Chemical manures are in good demand, and the works devoted to their manufacture are kept busy.

CEMENT.—In the cement trade business is still very active, the demand for the article, both on home and foreign account, being well sustained. A small factory which was started a few months ago at New Benwell, is now turning out 120 tons per week, the greater part of which is being shipped to America.

COPPER.—At a recent meeting of the directors of the Tharsis Copper Company, it was decided to pay a dividend equal to 10 per cent. per annum to the shareholders. The stock of copper at the Hebburn works of the company is very large, and operations are consequently being carried out on a somewhat restricted scale.

LEAD.—There continues to be a good local demand for sheet lead, and so far as this department of the trade is concerned, business may be said to be brisk.

THE COAL TRADE.—The shipments of coal and coke at Tyne Dock, for the week ending April 14th, amounted to 94,115 tons, an increase of 19,768 tons over the shipments for the corresponding week of last year.

BELFAST, 18TH APRIL, 1888.

SHIPBUILDING.—Trade still continues good, and higher rates of wages have been asked, and in some cases granted. All the stocks are full, and there are a large number of vessels in the water approaching completion. The immense new steamer for the White Star Company is now in frame, and Messrs. Harland & Wolff are pushing the work forward as much as possible. An order for a new passenger steel screw steamer of about 1450 tons, for the British and Irish Steam Packet Company, has been placed in the hands of Messrs. Workman, Clark, & Co., Limited, Belfast. She will be employed in their regular line of trade between London and Dublin, and is expected to be ready before the end of the year.

LINEN TRADE.—The market for yarns has been rather dull for the past fortnight, but though the sales have been small, the late prices still hold firm; stocks of wefts are increasing in the higher numbers. Sales have been steady, with a slight advance in prices in some cases. Tows are dull at late prices. The demand for cloths continues good at firm prices. Brown goods are firm and in good demand, and the looms are busy with forward orders. Sellers of finished linens are asking higher rates, but without avail.

PHOTOGRAPHY IN COMPRESSED AIR.

In the Air Chambers of the Caissons at the Forth Bridge.

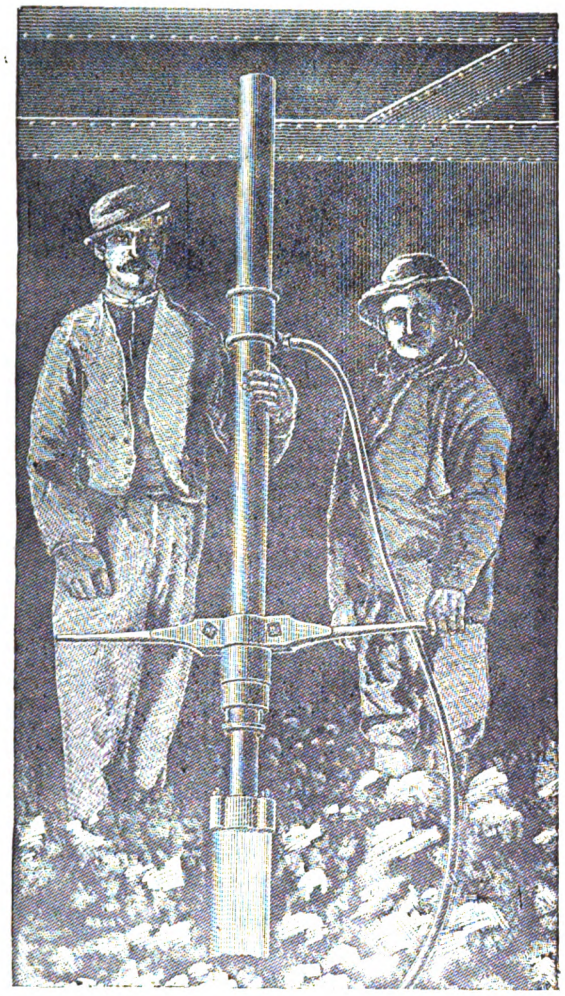

Fig. 1.

Fig. 2.

PHOTOGRAPHY IN COMPRESSED AIR.

By E. G. Carey, Assoc.M.Inst.C.E.

The founding of the main piers of the Forth Bridge afforded an opportunity—but rarely offered in this country—of testing the feasibility of obtaining photographs under air pressure considerably greater than that of the atmosphere. So far as the author is aware, no previous attempts had been made to employ photography under such conditions; the interest attached to the following experiments lies, consequently, in the novel surroundings attendant on their execution, and the difficulties encountered at every step, rather than in any degree of success attained. The views obtained, though serving as records of the work carried on in the air chambers, have no pretensions to photographic excellence, definition and sharpness of outline being impossible to attain in the peculiar atmosphere in which the plates were exposed. The caissons of the Forth Bridge have been already fully described in these pages (see *Industries*, Vol. III., page 148), and are therefore familiar to its readers. Hence it is unnecessary to again refer to them in detail. Suffice it to briefly state that they are constructed of iron, are 70ft. diam., and in exterior appearance closely resemble large gasometers. Built up on shore, they were launched on slipways, towed out to the site of the proposed pier, and filled with concrete till they rested on the bed of the Forth. Seven feet above the shoe, or lower edge of the caisson, is placed a floor forming the roof of the air chamber, which was in fact a large diving bell 70ft. diam. and 7ft. high, in which the work of excavation was carried on, the caisson sinking by its own weight into the hollow thus formed, until the final depth was reached. This air chamber was the scene of the experiments hereafter described. The greatest depth reached was between 80ft. and 90ft. below water level, and the pressure ranged up to 33lb. per square inch above that of the atmosphere. A trial was first made on shore at night, to obtain some data as to the requisite exposure. A group lighted by two arc lamps, each 1200 c.p., and carefully shaded, gave fair results with a rapid plate, the largest stop, and 10sec. exposure. This result formed the basis of the first attempt in the caisson. The roof and sides of the air chambers having been whitewashed, to aid in the diffusion of the light and render sharper the outline of dark figures against them, four rapid plates were exposed for 12sec., 20sec., 25sec., and 30sec. respectively, each with the largest stop in the lens; three arc lights, each of 1200 c.p., being employed to illuminate the group. The plates were found to be considerably under exposed, and no results of any value were obtained. It was now decided to considerably increase the length of exposure; accordingly, ten days later, a second series of exposures were made, of 5min., 10min., and 15min. duration, under the same conditions of lighting and in every way identical with the first experiments. The results on development proved again very disappointing, and failure had evidently to be traced to other causes than deficient exposure. In the third attempt it was accordingly arranged to test the effect of improved illumination, and negatives resulting from exposures of 7min. and 8min., with the largest stop, and five arc lights, or a total of 6000 c.p., carefully arranged so as to light the group most favourably, gave the first encouraging results, and fully demonstrated the importance of adequate illumination. In the fourth series of experiments, it was sought to gain enhanced results by the adoption of more rapid plates than those hitherto employed. Plates of XXXXX rapidity, manufactured by the Paget Prize Plate Company, of Ealing, were accordingly used with the same lighting power as in the third experiment. A further marked improvement ensued, exposure of 1½ and 2 minutes being given with the largest stop. Fig. 1, obtained at this juncture, has been selected as one of the most successful of the whole series. A fifth and final series of experiments were conducted during the founding of the last caisson, viz., that for Queensferry north-west pier. The author endeavoured, by increasing the lighting power, to produce a corresponding gain in definition and sharpness of outline in the groups. It has been already stated that five arc lights had been employed in the later experiments, each having 1200 c.p. The current, it may now be mentioned, was 12 ampères with carbons 10mm. in diameter, and an arc $\frac{1}{10}$in. in length. The attention of the author having been directed to the requirements of electric lighting for engraving purposes, where, in order to secure actinic rays of strength requisite for that class of work, a current of considerably higher strength is essential, he determined in continuing his experiments to employ arc lamps, having a current of at least 25 ampères with 13mm. carbons and an arc ¼in. to ⅜in. in length. Accordingly two Siemens arc lamps of 6000 c.p. each, a current of 30 ampères, an arc averaging ¼in., and Siemens B cored carbons 13mm. diam. (employed on account of the excellent white light they yield), were fixed in the caisson. The power available did not permit the employment of a larger number of lamps at the high current now adopted—a fact to be regretted, as doubtless greater diffusion of light from several sources would, as in former cases, have produced enhanced results. In former experiments the lamps had been suspended from the roof of the air chamber; for the final exposures it was, however, decided to place them on the boulder clay bottom, and to project the rays upwards by placing the positive pole below its fellow. It is doubtful, however, whether much advantage accrued from this arrangement. Fig. 2 has been selected from negatives obtained during the final experiments. The exposure was one minute, with the largest stop. Considerable discomfort to those present at these trials resulted from the high current employed; the symptoms in each case being identical, viz., intense irritation in the eyes, as if filled with sharp, gritty dust. It may be added that bathing the eyes with weak tea and milk—a standard remedy amongst electricians in such cases—alleviated the soreness, and in a few days all pain passed away. Shortly afterwards, the founding of the piers was brought to a successful termination, and with it the employment of compressed air at the Forth Bridge, terminating of necessity any further experiments in this branch of photography. The author was, however, assured by a photographic expert that the dense, hazy atmosphere of the air chambers insuperably debarred him from obtaining the highest results; and that, much as the specimens secured might leave to be desired, he could not in reason hope to improve much further on them. The haze, caused either by a sudden influx or a sudden expansion of air due to its escape, was a continued source of trouble throughout the experiments. No remedy could be found, save to run the air compressing machinery as slowly and regularly as possible, and then seize the moment of least fog for exposure. Some trouble was experienced at first by the formation of moisture on the lenses, due to the heat of the air chamber. The author was not unprepared for this, a similar difficulty having been experienced by Mr. W. D. Valentine, the eminent photographer of Dundee, when engaged in obtaining submarine photographs of the ruins of the old Tay Bridge, a difficulty which Mr. Valentine successfully overcame by rubbing a thin film of glycerine over the lens, and thus checking the formation of moisture. In the air chambers of the Forth Bridge, however, it was found that after a little time the lenses got warm, and the trouble then ceased. A glance at Fig. 2 demonstrates the advantages of light clothing when groups are taken under such conditions. Want of diffused light forms the great difficulty under such circumstances, and every device by which the few rays that are obtained can be diffused and aided should be utilised to the utmost. The lens used throughout these experiments was of the rapid rectilinear type made by Dallmeyer, and had 2½in. aperture and 18in. equivalent focal length. The size of plates was 12in. by 15in. The author is indebted to Mr. Valentine, who on two occasions accompanied him into the air chambers, for much valuable assistance and information; whilst it is due to the kind permission of Sir John Fowler and Mr. Baker, the engineers of the Forth Bridge, that the author has briefly sketched the chief points of interest, and the novel difficulties, in experiments as unique as interesting, carried out by their instructions.

MANUFACTURE OF COTTON IN JAPAN.

The total production of cotton per annum in Japan is officially estimated at 40,000,000lb., a quantity which is not sufficient to supply the requirements of the empire, so that the importation of cotton yarns and cotton goods is an important item in the foreign trade of the country. From a Foreign Office report, however, it appears probable that the imports of cotton manufactures will decrease, as the Japanese spinning industry has of late years received a great impetus. There are twenty-two old established mills at work, with an aggregate number of 76,000 spindles, and in addition to these, eight new factories have been started, with an aggregate of 117,000 spindles, being an increase in eighteen months of over 150 per cent. The *Japan Daily Mail* states that at this rate of progress it is evident that Japan, so far from continuing to afford a market for manufactured cotton goods, will herself ultimately become an exporter of them. It is pointed out that the situation of Japan is very favourable, as it is comparatively within easy reach of the great centres of cotton supply, is itself a cotton producing country, and has the command of cheap and skilful labour. Under such circumstances there is every reason to anticipate a steady and rapid growth of this branch of Japanese industry.

Advertisements intended for insertion in the current week's issue must reach the Manchester Offices not later than first mail delivery on Thursday morning. Scale of charges for displayed advertisements on cover and inside pages will be forwarded on application. Orders for single advertisements must be accompanied by payment in order to insure insertion, the charge for which is 2s. 6d. for the first four lines or under, and 8d. for each additional line; one inch and over at 7s. per inch; the line averages eight words. While all practical regularity in the insertion of serial advertisements will be observed, it can only be absolutely guaranteed in the case of those ordered to appear weekly.

All accounts are payable to the Publisher, JAMES F. BUTTERWORTH, *70, Market-Street, Manchester. Cheques should be crossed Manchester and Liverpool District Bank, King-street Branch, Manchester. Post Office Orders to be made payable at Manchester.*

Illustrated Abridgments	411-414

To Correspondents.

All communications intended for insertion in this Journal, or relating to Editorial matters, should be addressed to "THE EDITORIAL DEPARTMENT," either at the Manchester or the London Offices, and must, in all cases, be accompanied by the name and address of the writer. No notice will be taken of anonymous letters.

We cannot undertake to return manuscripts or drawings, and must request correspondents to keep copies.

Industries, VOLS. I., II., & III.

From July, 1886, to December, 1887.

A few Copies, handsomely bound in half calf, gilt lettered, may now be had at the Head Office, 70, Market-street, Manchester, Price 20s. each.

Industries:

FRIDAY, 20TH APRIL, 1888.

SCIENCE AND TRADE.

THERE are very few causes which do not suffer more from the injudiciousness of their friends than from the opposition of their enemies. The cause of scientific and technical education has certainly so suffered. Some of its extreme partisans look upon it as sufficient to cure all the ills from which society is suffering, and forget that unless beneath it all we have the strong fibre of healthy manhood, such education by itself only affords a quicker way of going to ruin. On the other hand, manufacturers are too apt to look upon it simply as a means for cheapening or bettering their products, and they only value it in so far as it does; and the sub-division of labour and the employment of machinery render technical instruction not so necessary for the hands he employs in his work as for the heads which direct it. Skilled engineers, chemists, or artistic designers are therefore what they insist is required, and they think technical education for the working classes altogether unnecessary. They argue that our workshops and manufactories are the best technical schools in the world, and that the chief want of the workmen is that they should be both sober and intelligent enough to carry out the instructions they receive from their managers. Again, we find some conservative enough to deny that we are inferior to any of the Continental nations in either science or practice, although they are willing to admit that from our past prosperity we have got into the way of taking things easily and allowing trade to push itself, whereas the Germans have been compelled, from their past conditions, to found technical schools and send their travellers all over the globe, and they are of opinion that what we require is rather a better commercial organisation for bringing our productions to the notice of our probable customers. In this, as in almost all other matters, there is some truth in each of these opinions, and if people would only learn to take a broad view of matters, they would soon see how the wants of the different classes of the community were to be met, and the demands of modern trade to be satisfied. We do require for the continued prosperity of our manufacturers men who have received the highest scientific training, as there can be no doubt that the inventions of the future which will revolutionise old industries or found new ones will only be possible to those who have undergone such a training. In proof of this, we have only to mention the discoveries of Bessemer and Siemens, which have revolutionised the iron and steel trade; of Wheatstone and Thomson, which have made telegraphy successful; of Young, which founded the paraffin oil trade; and of the German chemists, which have given them a monopoly of some of the chemical industries requiring high scientific skill. We further require a considerable number, although not so large as some people imagine, of men capable of acting as draughtsmen and foremen; but the great body of the working classes stand more in need of an education which will fit them to be good citizens, than one which is specially adapted to technical ends. Every opportunity should be given to those who really display original ability for improving their position; but the way from the workshop to the drawing office should not be too easy. Clerks have long been a drug on the market, on account of our present system of education, which inclines a man to starve on a pittance, if he can keep on his coat, rather than earn a good wage as an artisan. If such men would only combine some scientific training along with what they obtain in commerce, and if they paid more attention to modern languages, so that they might be able to meet the well trained graduates of Continental schools on something like equal terms, they would be more useful.

The foregoing considerations occurred to us after reading an article in a recent number of the *Contemporary Review*, by Sir Lyon Playfair, on "The Progress of Applied Science in its Effect upon Trade," in which he takes for his text a remark which he made some years ago, to the effect "that the world has not yet accommodated itself to the wonderful changes which science has produced in the modes of production and in the exchanges of commerce," and he contends that there are only two causes of the universal depression which at present prevails, viz.: (1) That the improvements in machinery, by new inventions, have produced great changes in the quickness and economy of distribution of commodities, and have profoundly altered the whole system of commerce; (2) that the improvements of machinery used in production have increased the supply of commodities beyond the demands of the world, and have too rapidly displaced the old forms of labour. He maintains that capital has suffered, during this long continued depression, more than labour. For some time past capital, when applied to staple commodities, is glad to be content with about 10 per cent. of the cost of conversion of raw material into a useful product, while labour gets 90 per cent. Of the 10 per cent. which goes to the capitalist only from 5 to 6 per cent. can be put to profit, the rest going to the wear and tear of the machinery. There is at present a want of harmony between capital and labour which tends to continue the depression. Sir Lyon Playfair remarks that sometimes working men, not content with the shorter hours of labour, put arbitrary limits to output and to the mode in which the workers shall be employed, and such restrictions, lessening the very narrow margin of profit that prevails, have stopped some works, and threaten to drive others from this country to foreign parts; and he contends that a better education of masters and men would show that the interests of capital and labour are not antagonistic, but identical.

Our space will not allow us to follow him in his purely economic speculations; but, having regard to Sir Lyon's position as an authority on scientific matters, we will briefly note a few of his remarks on the effects of science on trade. He mentions, in the first place, the changes produced by science in the economy of distribution, and the consequent and profound alterations which have followed in the commerce of the world. The opening of the Suez Canal in 1869 caused the old route round the Cape of Good Hope to be abandoned; and by the substitution of iron steamers for wooden ships, a tonnage estimated at two millions of tons was practically destroyed, and vast arrangements in commercial industry were displaced. In the old system of long voyages, large storehouses of goods had to be provided for the shipping interests, not only in foreign ports, but also in England, which became the centre of warehousing, banking, and exchange. All this was changed by the mighty power of electricity, which has not only revolutionised the method of effecting exchanges, but has also, through its various applications—the telegraph, telephone, and electric lighting—created new labour, and at the same time displaced a large amount of old labour. The Suez Canal and improved telegraphy made great demands

Digitized by Google

for quick and economical distribution of material. Numerous steamers were built between 1870-73 for this purpose; but so rapid were the improvements that they were nearly all displaced two years afterwards, and sold at half their cost. Iron has been largely substituted by steel both on land and sea, Bessemer's invention at first destroyed wealth; but, phœnix-like, new wealth has arisen from its ashes. The improvements in the marine engine have produced great economy of fuel, and a great reduction in the cost of transit has been the result. The raw material can thus be distributed at low charges, and England has, in consequence, lost its great advantages in the possession of coal and iron—the first, the source of power; the second, the material of strength. The value of raw material in industry is the lowest factor of production, while the value of intellect in converting it into utility in the cheapest and best way is the highest and dominating factor in manufactures.

Sir Lyon Playfair then proceeds to dwell on what he considers the second cause of the depression which now exists, viz., that modern inventions have produced commodities faster than the world could absorb them at remunerative prices, and in doing so have displaced old forms of labour with too great rapidity for its absorption by replacement, and this he illustrates by examples from chemical manufacture, only one of which we have space to mention, viz., the root called madder. This was grown as extensive crops in various countries of the world—Turkey, Holland, Belgium, France, and Italy—and gave employment to a large number of cultivators. Commerce was startled some time since to learn that chemists had succeeded in making the colouring principle of madder out of coal tar, and in a short time a great change took place in agriculture, commerce, and dyeing. Madder is still used to some extent; but its importation has decreased from 28,750,000lb. in 1872, to about 2,000,000lb. in 1887. Sir Lyon then mentions some of the effects of invention on the cotton trade, and on agriculture; but as these are generally pretty well known we will not repeat them, but the effect of railways may be noted. Through them a vast amount of the labour of men and horses has been displaced, but is replaced in other forms by feeding the railways with material. If the locomotives on English railways were annihilated, it would require the labour of 75,000,000 men, or of 12,000,000 horses, to carry on the traffic, in an inferior way and at a much larger cost; for the cost of carting a ton weight by a man with a cart and horse is one shilling per mile, while the railway carries it for a penny or under. The last illustration Sir Lyon gives is from the iron industry, and shows the various economies which have been effected not only in the main, but also in many subsidiary products.

The conclusion Sir Lyon draws is that the equation of the older economists—the product equals labour plus capital—is not correct. The product is actually the result of three kinds of labour—capital or accumulated labour, labour of quality, and labour of quantity; or reducing this to a simpler expression, the present state of manufactures depends mainly upon the intellectual condition of the producers, and he quotes statistics to show how much more the Germans are doing than we are in the way of education. It ought to be noted that it is chiefly in the education of leaders of industry. It is not yet too late, however, for us to hold our own in the ever increasing competition of the industrial world. There is no occasion for panic. Let us develop our newly established University Colleges, and extend our evening science and general classes, keeping, however, the practical part of the training of the students in the workshops or manufactories; and above all, let us not make the passage from the workshop to the college too easy, except to those of proved ability and energy; and without introducing any new machinery or organisation we shall be able to do all that is required at a comparatively small cost to the community.

THE BIMETALLIC CONFERENCE.

It may well be doubted whether much that is new can be said on the subject of bimetallism. For at least ten years there has been an almost continuous flow of bimetallic rhetoric, in the press and on the platform; and it might safely be assumed that all the arguments have been advanced, and all the objections answered. Yet the Bimetallic League may think that it has work before it, not precisely in the way of scientific pioneering, for that is not its function, but rather in popularising conceptions which in the minds of monetary reformers have long been commonplaces. To put the issue clearly before those who are not specialists in the science of money, and to stimulate public interest in a question that may ere long press for settlement at the polling booths, are, it would seem, the present functions of the League. One of the modes of exercising these functions is the holding of conferences, at which papers dealing with various aspects of the subject may be read. Such a conference was held in Manchester a few days ago, and although the recent changes in the relative values of the precious metals are just now a subject of Parliamentary inquiry, there was nothing in the least inopportune in this meeting of bimetallists, for the "battle of the standards" cannot be said to be either lost or won. The Bimetallic Conference, like most others convened by a single party in a controversy, was pervaded by perfect harmony. There was no possibility of discord, since there were no dissentients there. It is well for propagandist leagues to turn aside from time to time from the strife of controversy, and to rejoice in harmonious possession of their shibboleth, whatever it may happen to be. Leaving aside the very obvious charge of one-sidedness which has been in certain quarters pressed against the Bimetallic Conference, it were well to examine calmly what justification there is for the bimetallic propaganda, and what it may be expected to effect. Perhaps the primary justification for the advocacy of bimetallism as a new monetary gospel, is the circumstance that even among professed economists monetary science had almost fallen into desuetude. Jevons, and a few others who were adherents of the orthodox economics—if the views of the English critical group of whom Jevons was a member can be called orthodox economics—wrote well and impartially upon monetary problems and the movements of wages and prices; but the rank and file met all suggestions of the need of currency reform with a simple *non possumus*. The result was that currency came to be looked upon as subject to certain immutable laws with which it was quite impossible to interfere, and the Act of Lord Liverpool, which established our present monetary system, was assumed to have all the force of a law of nature. To the bimetallists belongs at least the credit of having shaken up the dry bones of monetary controversy, and of having directed anew the minds of economists to the history and the theory of money, while the serious price fluctuations of the past few years have given them ample material upon which to draw for illustration of their position. One might even go a step further, and say that the bimetallists have been largely unconsciously aiding in the development of a study of economics from the point of view of dynamics, as opposed to the older static method; and this service will remain to their credit after their frequent extravagances and unrealisable hopes are forgotten. Besides this justification on scientific grounds, the bimetallic propaganda might be justified on the ground that it occupies vigorously a position in the general circle of critical attack upon current conditions. However one may disagree with the positive proposals of an opponent, it is almost invariably useful to learn what one can from his criticism. Thus the constructive schemes and millennium visions in which some bimetallists and others indulge their imaginations, may, perhaps, be quietly ignored; but when they point to dislocation of commerce produced by changes in monetary legislation and to fluctuations in the supply of the precious metals, as affording reasons for a re-examination of the whole subject of money as an international question, it is impossible seriously to deny the need of such an inquiry. When we ask, however, what bimetallism may be expected to effect, we find room for vast divergence of opinion. It is one thing to agree with, for example, Sir H. Meysey-Thompson's statement that there has been "plenty of trade but no profit," and quite another thing to expect that bimetallism would mean increased profit. It is one thing to admit that the depression of prices has been largely due to currency causes, quite another thing to expect that the establishment of bimetallism would result in a general advance of prices. If there is any truth in the bimetallic position, the result of its establishment would be a steadying of general wholesale prices, not a rebound from the low prices now current. Nor would it probably have any immediate or even remote effect upon profits. It might contribute slightly to steady them—that it would cause them to rise is a theory inconsistent with the fundamental proposition of bimetallism. The fact is that currency movements, whether legislative or productive, form only one set in a complex system of movements, and it is as unscientific to give them an exaggerated value as it is to ignore them. It is to be expected that those who urge a special point should use special pleading; it is for the impartial public—impartial in this case, it may be said without offence, chiefly from ignorance—to discount the exaggerations, and apply a rigid test to the statements of the bimetallists. Some of these statements do seriously require the application of such a test. The address of the chairman, for instance, contained in rather an exaggerated form, indication of the existence in his mind of the cruder errors of the Mercantile School, which, long relegated to the limbo of exploded theories, seems inclined now to re-visit us. He said, for example, that "silver using countries have no money metal with which to discharge the balance of debts to England, but must send commodities." This is clearly a survival of the "mercantile" exaggeration of the importance of the settlement of the balance of trade by the transference of money metals. It is too old a controversy to re-open; but apart from theoretic objections, the statement might be called in question as to matter of fact. India is understood to have large gold hoards, which it could, if it were so disposed, remit to Europe in settlement of the balance of trade. Exports from India have indeed been stimulated by the fall in the exchange, and not because India has no "money metal" wherewith to settle her balances.

It may be held as proved, since very ample evidence to the effect appears in Mr. Inglis-Palgrave's Memorandum in the Third Report of the Royal Commission on the Depression of Trade, that silver prices in India have not risen, so that there is no apparent hardship in the Indian people being compelled, in their attention to their economic interests, to send their commodities rather than their money to us. While this is the case as regards people in India, there can be no doubt that the uncertainty and constant variation of the exchange has caused great commercial distress in this country, and that not because of the mode of settling international balances, but because of the downward tendency of gold prices, of which the fall in the exchange was the manifestation. Among the papers read at the recent conference was one by Mr. Samuel Smith, M.P., which speculated upon the effects which would follow the re-monetisation of silver; one by Professor Nicholson, attempting to reconcile the bimetallic theory of money with that of Adam Smith; and one by Professor Foxwell, upon "certain misconceptions in regard to the 'fixed ratio.'" In his paper Professor Nicholson pointed out that what is wanted is an international standard by which the fluctuations of prices due to monetary causes alone might be minimised, and he endeavoured to show that it is hopeless to construct such a standard with a single metal, either silver or gold, and that, therefore, the only practicable standard is a joint one. In Professor Nicholson's opinion, one of the leading characteristics of a good money, viz., stability, would be realised by bimetallism. Professor Foxwell's paper on the fixed ratio approached the subject from a slightly different point of view. He described the fixing of a ratio between commodities as of common occurrence, and pointed out that the vague ratio arrived at by the silver market is too haphazard and inconvenient. These papers together formed an exceedingly good summary of the bimetallic position, and from the point of view of the monometallists, seemed to demand serious answer. There are, however, larger aspects of the question with which none of the papers read at the conference dealt, and which, perhaps, it would have been impossible to deal on such an occasion. Among these is the question of a multiple standard, to which at the best bimetallism is but a stepping stone. If it be the case that the countries of the Latin Union are waiting for the report of the English Commission now sitting, and that they look to England to act, should the slightest encouragement to do so be offered in the report, it may be that Mr. Goschen's next surprise will be a proposal for an International Monetary Conference to succeed those of 1878 and 1881. Though it is not likely that much that is novel would be disclosed at such a conference, it would at least help in preparing the way for an international monetary system in the future, by which the increasing movements of commerce might be rendered possible with decreasing friction. The question of State interference with industry is hardly a valid one in this case. We have on numerous occasions expressed our disapproval of the undue interference of the State in industrial matters, whether for party purposes or for objects more worthy of general support, but as between State control of the Mint and *laisser faire* in the making of money, civilised nations have long decided. The question is not really now an open one. The discussion is practically between a State regulated *single* standard and a State regulated *double* standard. Neither monometallists nor bimetallists thus adopt in its fulness the principle of *laisser faire*.

EMPLOYERS' LIABILITY LEGISLATION.

We referred last week to this subject, but with special regard to the effect which the proposed legislative changes would have upon mine owners. The Government Bill now before the House is backed by the Home Secretary, the Attorney General, Mr. Ritchie, Mr. Forwood, and Mr. Stuart Wortley. The Bill shows that it is proposed to repeal the Act of 1880, but that the main principles of that Act are to be re-enacted, together with some additions which eight years' experience would seem to justify.

It will be remembered that previous to the Employers' Liability Act of 1880 an employer was not in general liable to a workman for an injury which was the result of (*a*) the employer's negligence in respect of certain defections in his machinery, or (*b*) the negligence of a fellow workman. The Act of 1880 made material changes in these respects; but where the injury was caused by the negligence of a fellow workman, the employer was only liable if the fellow workman was in a position of authority over the injured workman. The Act removed certain anomalies in the law, and was, we think, generally beneficial to both masters and men. Legislation of this kind does not often affect large minded employers, who make it their duty to see that their machinery and plant are of the best, and who look after the welfare of their workpeople. But it does affect a certain class of employers. For instance, an employer whose chief concern is his legal liability, would be led to take more care in the selection of a second hand boiler or hoist. There was nothing in the Act of 1880 to prevent employers and workpeople contracting to exclude the provisions of that Act, and it was said at the time that this would make the Act a dead letter; but experience has shown the prediction to be baseless. To a very large extent employers of labour now insure against their liabilities, and the extensive business done by several insurance companies dealing with this special risk show that the Act of 1880 has not been a dead letter. It has done good service, not the least being that it has paved the way for the present measure. As we mentioned last week, there is another Bill before the House, having for its object the amendment of the Act of 1880. This is backed by Messrs. Burt, Broadhurst, Joicey, Haldane, and Lockwood, and may be said to specially represent the interests of workpeople. It will be interesting to note where the two Bills differ. By Mr. Burt's Bill the employer would be liable for injuries arising "by reason of the negligence of *any* person in the service of the employer." The Government Bill limits the employer's liability to negligence on the part of workmen who have authority or supervision. Again, by Mr. Burt's Bill the amount of compensation is limited to £500, whereas by the Government Bill the limit is £150. Mr. Burt's Bill provides that any contract which excludes the provisions of the Act shall be void; but that in reckoning the compensation there must be deducted therefrom the amount paid by the employer or by an insurance company receiving a premium from the employer. The Government Bill avoids all contracts by which the benefits of the Act are surrendered except in one case. By Mr. Burt's Bill, where a person has a right of action against a sub-contractor, he shall have the same right of action against any superior contractor; but such superior contractor shall be entitled to be indemnified by the sub-contractor in respect of the negligence of whom or of whose servants the cause of action arises. Section 2 of the Government Bill deals with the question of sub-contracts.

Having given above the material points on which the two Bills differ, we may state that, on the whole, the Government Bill appears to be a reasonable measure, and would seem to deserve the support of both employers and workpeople. Legislation too often seems to be directed in favour of one class at the expense of another, though in time this brings an unhealthy reaction. This remark applies to a certain extent to Mr. Burt's Bill, which might give a serious check to the employment of capital. For instance, a company desires the construction of a certain work, and thinks it cheaper to have it done by contract. The contractor finds it convenient to have say the masonry work done by sub-contract. By Mr. Burt's Bill the company, who merely find the money, might be harassed by legal proceedings on the part of a workman of the sub-contractor. The liability for compensation should be on the person who is morally responsible for the injury; and this, we think, is clearly provided for in the Government Bill.

Particular care must be taken not to deter owners of capital from employing it to the general advantage of the community at large, as industrial enterprise obtains its success from the wise union of capital and labour. The greatest foresight should be used to see that legislation intended for the benefit of the workman does not ultimately have the reverse effect.

Telegraph Cable.—The Spanish Government is in treaty with a foreign company for the establishment of a telegraph cable between Spain and the Balearic Islands.

Letters to the Editor.

STEEL SLEEPERS.

To the Editor of "Industries."

Sir,—Referring to the abstract of the paper on "Steel Sleepers" read before the Civil and Mechanical Engineers' Society on the 18th January, 1888, by Mr. H. T. Munday, Assoc. Mem., which appeared in your issue of the 6th inst, I think it is a matter for regret that the author did not enter more freely into the subject, which is one of great importance to railway companies as well as to the iron trade and kindred industries of this country, which require all the assistance they can obtain to maintain their position and keep their works going. To quote the words of a late president of the Iron and Steel Institute, "The change from timber to metal sleepers would be in importance second only to that of iron to steel rails."

Mr. Munday in his paper does not give the comparative cost of the few types of sleepers alluded to, nor the length of time they have been in use, the cost of maintenance, &c. This information would have been interesting to myself, and doubtless to many of your readers, as the subject is one that demands full consideration, having regard to the increasing weight of engines, rolling stock, and loads carried at higher speeds and at more frequent intervals over the permanent ways, which have to bear the whole burthen of the traffic, while allowing but little time for the necessary inspection, adjustment, or renewal. It is obvious that any real improvement in the *matériel* of this department of railway work would be a boon to the shareholders. It would also tend to diminish the cares of the directors and chief officials of our railways, and conduce to the safety of the travelling public, as the judicious use of the block system of signalling and continuous brakes have done. I hope to be able to allude at length to this subject at an early date; but, in the meantime, this letter may lead to the ventilation of this important matter by some of the readers of *Industries*.

Yours, &c., L. L.

Manchester, 17th April, 1888.

ON THE COST OF CENTRAL STATION LIGHTING.

To the Editor of "Industries."

Sir,—In my letter to last week's *Industries* I notice that only 1200 yards of useful frontage have been estimated for instead of 12,000 as suggested by Mr. Crompton. This of course makes a very considerable difference in the total cost of the proposed scheme, and therefore I would make the paragraph on the last column commencing "The supply mains would be laid," &c., read as follows:—

The supply mains would be laid underground from the engine house to the exterior of the area of supply, and I have considered that at this point they would branch off into ten distributing mains along 12,000 yards of useful frontage within the area of the supply. The cost of the supply mains up to the area carrying 300 ampères at 2000 volts would be about £1,600. For the distributing mains, which might carry a maximum of 30 ampères at 2000 volts, about £1,300 might be allowed. This is on the supposition that there are no secondary distributing mains, but that the primary current is led throughout the whole district, viz. 12,000 yards. As regards transformers, I assume for the moment that one instrument is provided for every two houses, and therefore about five hundred will be necessary. For laying conductors, opening streets, &c., I believe 10s. per yard will be a fair amount, or £6,880 for the 13,760 yards opened altogether. My estimate would therefore read as follows:—

Buildings, &c.		£6,500
Boilers, &c.		5,320
Engines, &c.		7,200
Dynamos, &c.		7,000
Supply mains	for primary current	1,600
Distributing mains	for primary current	1,300
Laying mains		6,880
Transformers		2,700
Fixing transformers		1,800
Station fittings, &c.		500
Total		£40,800

Or about £4. 1s. 6d. per lamp.

I must, however, say that on no account would I advise an undertaking of this nature to be carried out on these lines. The problem given by Mr. Crompton is altogether too vague and indefinite to form a criterion as to the relative merits of the two systems.

Yours, &c.,
J. Kenneth D. Mackenzie.

Westminster, 17th April, 1888.

"FUEL AND WATER," BY SCHWACKHÖFER & BROWNE.

To the Editor of "Industries."

Sir,—I have recently perused this volume, and find that, notwithstanding the high encomiums which greeted its publication some four years ago, one section of the book is so entirely erroneous as to be practically meaningless, owing to the fact that the figures do not bear any relationship to the formulæ enunciated. One of your contemporaries, when reviewing the book, said: "We confidently recommend this work to students. The section on heat is one of the best and most lucid ever written." Another said: "The practical utility of the volume is beyond question;" a third that "The reader has every guarantee for the soundness of the work, which will be readily purchased by all users of steam and water;" and a fourth that it would be "A welcome addition to the engineer's library. Gathering within itself many facts and data of physical science, often difficult to find when required, it will serve as a useful book of memoranda to the scientific engineer." No doubt the foregoing eulogies apply to the general principles set forth in the volume, and it is therefore the more to be regretted that, in the comparatively elementary process of applying the general principles to actual examples, the figures have got so far astray. With your permission I will proceed to state the corrected figures in such a form as will be of use both to those of your readers who have and have not the volume in question. Chapter III. treats on heating apparatus, which is divided into three principal parts, viz.: (1) The furnace, with grate and ash pit; (2) the flues; (3) the chimney; and after a general dissertation on each of these heads the author proceeds to treat on the "useful effect of furnaces (with examples of calculations)." It is in these examples of calculations that the figures get astray.

Example I.

commences on page 115, and merely noting that we here find "1675" (kilos.) printed instead of "16,752 litres," we pass on to the data upon which the calculations for arriving at the "useful heat" are based. They are as follow:—

Chemical composition of coal:

		Per cent.
Carbon		69·77
Hydrogen		2·72
Nitrogen		0·46
H_2O (in chemical combination)	13·45	
H_2O (hygroscopic)	3·25	
		16·70
Ashes		10·35
		100·00

Composition of chimney gases, per cent. of volume:

CO	0·0
CO_2	12·2
Air	38·6
N	49·2
	100·0

Mean temperature of chimney gases	200°C.
„ „ air	25°C.
Moisture of air, per cent. by weight	0·8
Water evaporated per kilo. of coal burnt	9·097 kilo.
Temperature of feed water	58°C.
„ steam	155°C.
Water carried over in steam	1·3 per cent. by weight.
Weight of cinder per kilo. of coal burnt	0·113 kilo.
Analysis of cinder	0·0137 kilo. carbon. 0·0993 kilo. ash.

The first error which we have to note is in the "air theoretically needful for complete burning of 1 kilo. of coal," which is stated as = 9·17 kilo. On page 43 we find it stated that "the weight of air L required for one unit of fuel is given by the formula

$$L = \frac{11{\cdot}696C + 35{\cdot}088H}{100}$$

where C is the percentage of carbon, and H that of free hydrogen in the fuel." The weight of air theoretically needful for complete burning of 1 kilo. coal of above analysis should therefore be 9·11 kilo., and not 9·17, as stated.

We next find an error in the calorific value of the fuel. The formula for this, a modification of Dulong's, is given on page 45 as follows:—

$$p = \frac{8080C + 29633H - 637W}{100}$$

where p is the absolute heating power of the fuel, and C, H, and W are respectively the percentages of carbon, free hydrogen, and chemically combined or hygroscopic water. Applying this formula to the analysis of coal stated above, we find the absolute heating effect of the fuel to be 6337 calories, instead of 6600, as stated, and from this of course it follows that the theoretical figure of evaporation of water at 0°C. to steam at 100°C. is 9·95 kilo. of water per kilo. of coal, instead of 10·4 kilo., as stated.

The calculations determining the useful heat, and apportioning the heat lost, are as follow:—

I.—Heat Lost in Chimney Gases.

(*a*) Volume of each kind of gas in a weight unit, by analysis, which see above.

	Weight of a litre in grammes.		Parts by volume.		Parts by weight.
Carbonic acid	1·9666	×	12·2	=	23·993
Air	1·2936	×	38·6	=	49·933
Nitrogen	1·2566	×	49·2	=	61·825

(*b*) Weight of each kind of gas per kilo. of coal burnt. 1 kilo. of coal contains 0·6977 kilo. of carbon; of this there fall into the ash pit 0·0137 kilo., and are burnt 0·684 kilo. Three kilo. C give, when completely burnt, 11 kilo. CO_2; hence

$$\frac{0{\cdot}684 \times 11}{3} = 2{\cdot}508 \text{ kilo. } CO_2 \text{ per kilo. of coal.}$$

To 23·993 CO_2 correspond 49·933 air; hence

$$\frac{49{\cdot}933 \times 2{\cdot}508}{23{\cdot}993} = 5{\cdot}219 \text{ kilo. of air per kilo. of coal.}$$

To 23·993 CO_2 correspond 61·825N; hence

$$\frac{61{\cdot}825 \times 2{\cdot}508}{23{\cdot}993} = 6{\cdot}463 \text{ kilo. of N per kilo. of coal.}$$

The water in the chimney gases is made up as under:—

1. Water contained as such in the coal (0·167).
2. Water from combustion of available hydrogen (0·0272 × 9 = 0·2448).
3. Water in incoming air.

Here we come upon a confusion of terms, and an irregularity in the method of computation. It is stated that 77N correspond to 100 air, and upon this basis the quantity of air used in combustion is computed, and then 0·8 per cent. for watery vapour is added. Later on we find that the air computed on the basis of 77N : 100 air is described as atmospheric air. Now, "atmospheric air" means air in the condition of the then existing atmosphere, that is to say, including its 0·8 per cent. of moisture. The term atmospheric is therefore wrongly applied, as it is applied to air (N_4O) without the moisture. The calculation is

Digitized by Google

however, also wrong, for taking air as N_4O, 77N—would correspond to 220 = 99, and not 100 air. The correct computation of the air used in combustion will be as follows:—

Atmospheric air	100·00
Less moisture	0·80
	99·20 N_4O

= 77·15 units of N plus 22·05 units of O. 77·15 weight units of N therefore correspond to 99·20 weight units of air; hence

$$\frac{6{\cdot}463\times99{\cdot}20}{77{\cdot}15}=8{\cdot}310 \text{ kilo. of air used in combustion;}$$

and vapour with above air

$$=\frac{6{\cdot}463\times0{\cdot}80}{77{\cdot}15}=0{\cdot}067 \text{ kilo.}$$

No note is taken by the authors at the foregoing stage of the ·0046N originally present in the coal, presumably because it would not make any practical difference in the results; it would, however, have been more regular to have shown this.

The weight of the excess air having been computed above as dry air, the 0·80 per cent. moisture must be added; hence, vapour along with excess air

$$=\frac{5{\cdot}219\times0{\cdot}80}{99{\cdot}20}=\cdot042 \text{ kilo.}$$

The total incoming air and vapour per kilo. of fuel burnt will therefore be

8·310 air used in combustion,
5·219 excess air.

Total, 13·529 kilo. instead of 13·613, as stated.

The total vapour brought in will be

0·067 along with air used in combustion,
0·042 along with excess air.

Total, 0·109 kilo. instead of 0·110, as stated.

The total vapour in chimney gases will be

0·4118 kilo. from the coal,
0·1090 kilo. with the air.

Total, 0·5208 kilo. H_2O instead of 0·5218, as stated.

(*c*) Calculation of heat capacity of chimney gases:—

	Kilogrammes.	Specific heat.	Heat capacity.
Carbonic acid	2·509	× 0·2160	= 0·542
Air	5·219	× 0·2375	= 1·239
Nitrogen	6·463	× 0·2438	= 1·576
Steam	0·521	× 0·4805	= 0·250
Total			3·607

(*d*) Calculation of heat capacity of entering air:—

	Kilogrammes.	Specific heat.	Heat capacity.
Air (N_4O)	13·529	× 0·2375	= 3·213
Steam	0·109	× 0·4805	= 0·052
Total			3·265

instead of 3·286, as stated.

(*e*) Calculation of heat lost in chimney gases:—

	Heat capacity.	Temp. (deg. C.)	Calories.
In chimney gases	3·607	× 200	= 721·4
Less brought in by air	3·265	× 25	= 81·6
Loss			639·8

II.—Heat Lost by Coal Falling in Ash Pit.

The residue per kilo. of coal consists of:—

0·0137 kilo. carbon.
0·0993 kilo. ash.

Kilo. C.	Heat value.	Calories.
0·0137	× 8080	= 110·7

III.—Heat Lost in Priming Water.

For each kilo. of coal burnt there were:—

8·9787 kilo. water actually evaporated.
1·3 per cent. or 0·1183 kilo. water carried over as liquid.

Total..... 9·0970

Kilo. of water.	Temp. of water in boiler.	Temp. of feed water.	Calories.
0·1183	× (155	− 58)	= 11·5

IV.—Heat Lost by Conduction of Radiation through Walls.

The total heat of evaporation by Regnault's formula

$$W t=606{\cdot}5+0{\cdot}305\,t$$

is stated as follows:—

$$8{\cdot}9787\times(606{\cdot}5+0{\cdot}305\times155-58)=5349{\cdot}5 \text{ calories.}$$

This, however, would be more intelligibly and correctly stated as follows:—

$$8{\cdot}9787\left\{606{\cdot}5+(0{\cdot}305\times155)-58\right\}=5349{\cdot}28 \text{ calories.}$$

The total losses are stated as:—

Heating effect of coal.		Heat utilised.		Calories.
6600	−	5349·5	=	1250·5
6337	−	5349·3	=	987·7

This, however, subject to the foregoing corrections, will now be:—

and hence the loss by conduction and radiation, which is given as:—

$$1250{\cdot}5-\overbrace{(639{\cdot}4+110{\cdot}7+11{\cdot}5)}^{\text{Special losses.}}=488{\cdot}9 \text{ calories}$$

will now be

$$987{\cdot}7-(639{\cdot}8+110{\cdot}7+11{\cdot}5)=225{\cdot}7 \text{ calories.}$$

The corrected resumé will then read:

From 100 kilo. of coal burnt

$\frac{5349{\cdot}3\times100}{6337}=84{\cdot}41$ kilo.	utilised instead of	81·05 as stated.
15·59 kilo.	lost „	18·95 as stated.
100·00		100·00

This loss is made up as follows:—

1. Escaped in chimney gases:
$\frac{639{\cdot}8\times100}{6337}=10{\cdot}10$ per cent. instead of 9·69 per cent.
2. Incomplete combustion; coal in ash pit:
$\frac{110{\cdot}7\times100}{6337}=1{\cdot}75$ per cent. instead of 1·68 per cent.
3. Priming water:
$\frac{11{\cdot}5\times100}{6337}=0{\cdot}18$ per cent. instead of 0·17 per cent.
4. Conduction and radiation:
$\frac{225{\cdot}7\times100}{6337}=3{\cdot}56$ per cent. instead of 7·41 per cent.

Total, 15·59 per cent. instead of 18·95 per cent.

Example II.

This is similar to Example I., but with a different analysis of fuel, and a more complicated analysis of chimney gases. The absolute heating effect is correctly given, but the "air theoretically needful for combustion" is stated as 6·74 kilo., instead of 6·70 kilo. There are several printer's errors, the most important being that of the omission of the water arising from combustion of H, from the statement of total water in chimney gases. It is worth while noting that there is a want of uniformity in the method of computing the quantities of air and moisture. In Example I. the quantity of dry air was computed, and a percentage of moisture *added*. We now find in Example II. that the quantity of dry air is computed in exactly the same way as in Example I., and a percentage *deducted* from it for moisture. The equation for calculation of heat lost by radiation is again irregularly stated, but there are no errors of sufficient moment to make any material difference in the results given in the *resumé*.

Example III.

This is an example of the results of four boilers at work in a group, with an economiser for heating the feed water. The data for the calculations are as follow:—

Composition of coal:

	Per cent.
Carbon	75·56
Hydrogen	2·45
Nitrogen	0·76
H_2O (in chemical combination)	10·39
H_2O (hygroscopic)	1·56
	11·95
Ash	9·28
	100·00

Mean composition of chimney gases:

	Boiler No. 1.	2.	3.	4.
CO	0·0	0·0	0·0	0·0
CO_2	4·8	6·2	5·3	4·6
Air	74·6	68·3	72·2	75·3
N	20·6	25·5	22·5	20·1
Mean temperature of chimney gases	353°	410°	372°	340°C.

Temperature of air	27°C.
Moisture in air, per cent. by weight	1·10
Water evaporated per kilo. of coal burnt	6·742 kilo.
Water carried away in steam, per cent. by weight	2·8
Mean temperature of feed water	118°C.

Composition of chimney gases, per cent. of volume:—

	Before economiser.	Beyond economiser.
CO	0·0	0·0
CO_2	4·8	4·1
Air	74·6	78·6
N	20·6	17·3
Temperature of chimney gases	340°C	202°C.

Temperature of feed water entering economiser	10°C.
Temperature of air entering economiser	30°C.
Moisture per cent. of weight	1·07
Weight of cinder per kilo. of coal burnt	0·113 kilo.
Analysis of cinder	0·024 carbon. 0·089 ash.

At the outset we find that the following values, which are to be calculated in the same way as described in Example I., are erroneously stated.

The absolute heating effect stated as 7100 calories should be 6755 calories.

The theoretical figure of evaporation stated as

$$\frac{7100}{637}=11{\cdot}15 \text{ kilo.}$$

should be

$$\frac{6755}{637}=10{\cdot}60 \text{ kilo.}$$

The air theoretically needful for complete combustion of 1 kilo. of fuel, stated as 9·76 kilo. should be 9·69 kilo.

The calculation of air actually used is again erroneously taken as 77N : 100 air, and 1·1 per cent. added for moisture. It is not worth while here again recapitulating the whole of the figures as in Example I., on account of this difference; but we will take them as they stand until we come to the calculation for loss of heat by conduction and radiation. Up to this point the losses which have been determined are as follow:—

	Calories.
I. Heat Lost in Chimney Gases	2968·4
II. Heat Lost by Coal Falling in Ash Pit	193·9
III. Heat Lost by Priming Water	6·1
Total	3168·4

We now come to

IV. Heat Lost by Conduction and Radiation.

The useful heat is stated in the old form, to which we took exception in Example I., as

$$6{\cdot}558\times(606{\cdot}5+0{\cdot}305\times151-118)=3505{\cdot}9 \text{ calories.}$$

The total loss, and loss by radiation and conduction, are then stated as follow:—

Heat value of coal.		Heat utilised.		Loss.
7100	−	3505·9	=	3594·1

Loss by radiation and conduction:

$$3594{\cdot}1-\overbrace{(2968{\cdot}4+193{\cdot}9+6{\cdot}1)}^{\text{Special losses.}}=425{\cdot}7 \text{ calories;}$$

these however, should be

$$6755-3505{\cdot}9=3249{\cdot}1 \text{ total loss,}$$

and $3249{\cdot}1-3168{\cdot}4=80{\cdot}7$ calories loss by radiation and conduction.

The corrected resumé will then read as follows:—

Of 100 kilo. of coal burnt

$\frac{3505{\cdot}9\times100}{6755}=51{\cdot}90$ kilo.	utilised instead of	49·38 as stated.
48·10 kilo.	lost „	50·62 „
100·00		100·00

This loss is made up as follows:—

1. Escaped in chimney gases:
$\frac{2968{\cdot}4\times100}{6755}=43{\cdot}95$ per cent. instead of 41·81 per cent.
2. Incomplete combustion.
$\frac{193{\cdot}9\times100}{6755}=2{\cdot}87$ per cent. instead of 2·73 per cent.
3. Priming water:
$\frac{6{\cdot}1\times100}{6755}=0{\cdot}09$ per cent. instead of 0·08 per cent.
4. Conduction and radiation:
$\frac{80{\cdot}7\times100}{6755}=1{\cdot}19$ per cent. instead of 6·00 per cent.

Total, 48·10 per cent. instead of 50·62 per cent.

The economiser results are as follow:—

The water was heated from 10°C. to 118°C., corresponding to $(118-10)\times6{\cdot}742=728$ calories per kilo. of coal. Owing to the original error in the calorific value of the fuel, the useful effect of the economiser per 100 kilo. of coal burnt is incorrectly stated. It should be

$$\frac{728\times100}{6755}=10{\cdot}77 \text{ kilo. instead of 10·25 kilo.,}$$

and the total useful effect of boiler and economiser combined is

therefore $51{\cdot}90+10{\cdot}77=62{\cdot}67$ per cent.
instead of $49{\cdot}38+10{\cdot}25=59{\cdot}63$ per cent. as stated.

Askam-in-Furness, 14th April, 1888.

Yours, &c.,
R. M. Wight.

SHIPBUILDING NOTES.

Mr. David MacBrayne, the owner of the well known West Highland coasting steamers, is about to make an important addition to his fleet. The "Fusilier," which was launched on Saturday, the 14th inst., by Messrs. J. MacArthur & Co., Paisley, is a handsome paddle steamer 200ft. by 21ft. 6in. by 8ft. 3in. The engines of the "Fusilier" will indicate upwards of 900 h.p., and will be made by Messrs. Hutson & Corbett, Glasgow.

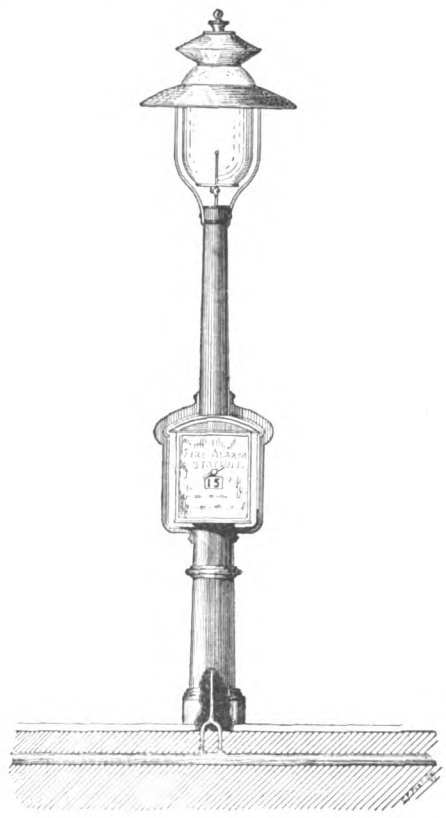
Messrs. Scott & Co., Glasgow, launched on Monday, the 16th inst., the "Ruby," an iron screw steamer 175ft. by 26ft. 6in. by 13ft. The "Ruby" is built with a cellular bottom, and is entered in Lloyd's highest class. Messrs. W. King & Co., Glasgow, will supply the engines, which will be triple expansion, the cylinders being respectively 15in., 25in., and 40in. diam., by 30in. stroke. The "Ruby" has been built to the order of Mr. William Robertson, Great Clyde-street, Glasgow.

Messrs. Archibald Macmillan & Son, Dumbarton, launched on Saturday, the 14th inst., the "Volunteer," a composite screw steamer, built for the Government for mail and passenger service on the coast of Newfoundland. The dimensions of the "Volunteer" are 190ft. by 30ft. by 22½ft. The gross tonnage is 750 tons, and the engines, which will be of 800 i.h.p., will be constructed by Messrs. D. Rowan and Son, Glasgow.

THE VARIATION OF THE CO-EFFICIENT OF SELF INDUCTION.

At the last meeting of the Physical Society, Mr. W. E. Sumpner read a paper on the above subject, in which he pointed out that the co-efficient of self induction of a coil whose magnetic circuit is wholly or partially composed of iron is a variable quantity, and should be defined more exactly than has hitherto been done. It is the ratio of the induced electromotive force to the rate at which the current is changing, and since the induced electromotive force is equal to the rate at which the magnetism is changing, the ratio in question is the rate at which magnetism changes with the current. From this it follows that if a curve be drawn whose abscissæ represent the current, and whose ordinates represent the amount of magnetism, or the number of lines of force through the coil, the co-efficient for any particular current will be represented by the rate of slope of this curve. The shape of these curves is well known from the researches of Professor Ewing, Dr. Hopkinson, and others. The curve slopes generally very little at first, but becomes more and more steep as the current increases. When the iron becomes saturated the curve bends over again, and the slope becomes ultimately very small. When the current is diminished, the curve of magnetism, owing to magnetic hysteresis, does not return on itself, but becomes steeper and steeper

Digitized by Google



as the current is diminished. The co-efficient of self induction for increasing currents should therefore at first increase and afterwards decrease, while for decreasing currents it should be small at first, but steadily increase as the current is brought towards zero. Many experiments made on an electromagnet, on the field magnets of dynamos, and on a Kapp transformer, have completely confirmed these conclusions. Owing to magnetic hysteresis, the number of lines of force enclosed by the coil will depend not only on the current flowing at the moment, but also on those that have been flowing previously; and for the same reason the co-efficients will depend on the previous history of magnetisation, and may be obtained of almost any value by previously using suitable magnetising currents. The hysteresis in the case of the Kapp transformer was very marked. If the co-efficient is a variable, the time taken for a current to rise to a given fraction of its steady value will depend on the amount of this current. If the final current is large, it will rise to its full value much more rapidly than if the final current is small. If the electromotive force is only such as to maintain a small current, the current will increase most rapidly at first, and with less and less rapidity afterwards. If, however, the final current is large, it will increase rapidly at first, more slowly afterwards, then with great rapidity, and will attain its final value slowly. When the steady current is large enough to magnetise the iron far beyond suturation, this effect may be very marked, and has actually been observed experimentally by Professor Thompson. The general effect of the variation of the co-efficient of self induction is to introduce ripples into the curve obtained on the assumption that the co-efficient is a constant and equal to the mean of the different values. It is generally assumed in calculations connected with alternating currents that the electromotive force of the dynamo is a sine function of the time, and that the co-efficient of self induction is a constant. These assumptions are supposed to be sufficiently true for practical purposes, but the author considers this doubtful.

Experiments made on the Ferranti dynamo at the Central Institution have shown that the electromotive force curve is such that its ordinates differ from those of the most favourable sine curve by as much as 10 per cent. It is probable that with some dynamos the curve of electromotive force consists of the sum of two sine curves, one with a period corresponding with the current alternations, the other having a small amplitude and a period corresponding with the revolutions of the dynamo. This will occur if there is any want of symmetry in the machine. Whenever this occurs the effect of induction will be to magnify the sine wave of large period in comparison with the wave of short period, as Professor Perry has pointed out, and the consequence will be that the current curve will differ in a marked degree from a simple sine curve, since any want of symmetry in the dynamo will be much magnified, especially at high speeds. That alternating currents are not generally simple sine waves seems to be indicated by the well known pulsations to which electric lights fed by alternating currents are subject. These pulsations are too slow to be due to the ordinary current alternations, but might be in time with the revolutions of the dynamo.

Although it is well known that self induction always delays the rise and fall of currents, it does not appear to have been noticed that it may, under certain circumstances, hasten the discharge of a condenser. If the plates of a charged condenser be connected by a wire, the discharging current has both to rise and fall. The effect of self induction is to delay both. It always delays the fall of the current more than the rise, because while the current is rising the condenser is far more highly charged. If the self induction be not too great, the condenser will discharge quicker than when self induction is not present. It is always possible to halve the time the condenser takes to discharge by using a suitable amount of self induction. As a lightning discharge is essentially the same as the discharge of a condenser, it seems likely that a lightning conductor of iron will be better than one of copper, because the former has more self induction than the latter. Dr. Lodge has recently shown experimentally that the iron conductor is the better of the two, but the author does not consider his suggested explanation as necessarily the right one.

THE NEW YORK FIRE TELEGRAPHS.

There is perhaps no town in the world where fire telegraphy is developed to such an extent as in New York. As was shown by Herr Fischer von Treuenfeld, in the paper he recently read at the Society of Telegraph Engineers and Electricians, London and other English towns compare very unfavourably with many Continental towns in the matter of fire telegraphs; but even Continental towns are quite eclipsed by New York in this respect, whilst fire telegraphy is hardly less fully developed in Philadelphia, Washington, and other American towns. The New York fire telegraphs are all centralised, the wires from the street calls being carried to the central office of the fire department, which is in telegraphic communication with the local fire stations. The circuits start from the office switch board, and pass out to the call points and local stations underground. For these circuits Waring anti-induction lead covered cables are used. The annexed illustration shows the connection of a street call with the underground cable, and in most cases the call boxes are combined with the existing lamp

posts. Where the circuit passes from underground to overhead, the junction is made by a box containing lightning arresters, which is placed on a pole, and the cables pass inside the hollow pole to the boxes, from whence the aerial lines radiate. All alarms are received at the central station, and the particular call box from which the alarm is sent is indicated on an annunciator board. The information is then telegraphed to the neighbouring local fire stations, where by means of a current the doors of the engine house are automatically opened, the horses are loosened, and the men are called up, and slide down on vertical poles from their sleeping apartments to the engine, as it would take up too much time if the brigade were to walk downstairs in the usual way. The time which elapses between the giving of the alarm and the starting of the engines is often less than half a minute. The Waring cables were first introduced for fire telegraphy in 1884, and about 285 miles are now laid down in New York, Philadelphia, and Washington.

CENTRAL STATION LIGHTING.

(Transformers v. Accumulators.)

Under the above title Mr. R. E. Crompton read an interesting paper at the meeting of the Society of Telegraph Engineers and Electricians, held on 12th inst. This paper, as the author states in his preface, is the outcome of the discussion which took place on the papers by Messrs. Kapp and Mackenzie, read some weeks ago before the same society: and it may also be regarded as an amplification of an article by Mr. Crompton, which was published in our issue of the 16th of March, page 276. The object of the paper was to show the comparative cost in first outlay and maintenance of two central electric light stations, each for a total of 15,000 glow lamps fixed, of which 10,000 are lighted simultaneously during the hours of maximum supply; one of these stations laid out on the alternating current system, and the other on the battery system.

The author divided electric supply schemes into two classes. First, those confessedly carried out in a temporary manner, and for the purpose of popularising the electric light, and inspiring the confidence of the public in supply companies as a form of investment, and, secondly, those intended to be of as permanent a nature as the gas supply with which they come into competition. He relegated to the first class such systems of supply as are in use at Brighton, Eastbourne, and London (Grosvenor Gallery), and, in fact, all stations which distribute electricity by means of overhead wires, picking their customers here and there, but which cannot be considered fit for a general system when the time arrives that more than half the houses in the district take the light. As regards supply stations of a permanent character, the author thinks that load diagrams, such as are taken by gas companies, should form the basis of the design. He exhibited three such load diagrams, one being representative of an ordinary London residential district, and the two others of American electric lighting stations. On the basis of the London diagrams he finds that the average daily output in units throughout the year is about three and a half times the maximum load in kilo.-watts; in other words, that a station designed for a maximum supply of 10,000 16 c.p. lamps simultaneously alight could not reckon upon selling more than an average quantity of 2100 Board of Trade units per day. In this connection the author drew attention to our article of the 2nd December, 1887, where the average output of a similar station was estimated as 3600 Board of Trade units, which estimate he considered excessive. In order to sell 2100 units it would be necessary that the supply should reach at least 1000 houses, representing a useful frontage of 10,000 yards; but on the supposition that only two houses out of three would take the light, and adding the length of mains required for crossings, and those portions which do not front the houses, he estimates that at least 20,000 yards of double mains would have to be laid. He assumes the generating station to be 2000 yards distant from the centre of the district supplied, so that in all there must be provided 22,000 yards of double mains. As regards the cost, the author prepared Tables I. and II. (see next page), the first of which refers to cables protected by insulation, and the second to a class of underground mains lately introduced by the author in his Kensington Court installation. These mains consist of bare copper strips supported on insulators within a brick and cement culvert.

Mr. Crompton, in referring to these tables, adversely criticised the habit of basing systems of distribution on the cost of copper, with but a small percentage added for insulation and laying, as liable to lead to erroneous calculations, and giving a fictitious value to high pressure distribution. He also alluded to the great difficulties which will be encountered in laying underground mains, which have to carry currents at 2000 volts pressure. As an example of the system advocated by the author, he cited the Vienna central station, where four groups of storage cells, each containing fifty-two cells, are charged in series, the pressure varying from 430 volts at the time the batteries are giving off currents, to 480 volts at the shorter time during which the charge is being completed. This includes the loss in the mains, the generating station being 1400 yards from the distributing station. During five hours of lighting, about two-thirds of the current comes direct from the dynamos; but during this time, for short periods, the demand for current often increases to such an extent that these proportions may be reversed, and the batteries supply two-thirds of the total. This system has been in use for upwards of nine months without any hitch or trouble in connection with the electrical work, and the author therefore considers it proved that there is no danger or difficulty in using currents of 480 volts, when the charging circuit is permanently connected to the distributing circuit.

A comparison between the two rival systems of distribution was made from four points of view: First, trustworthiness, steadiness, and quality of the lighting; second, first cost of the plant; third, the working cost and maintenance; fourth, probable output and maximum income which can be obtained in each case. The author took it for granted that the storage system must be superior to a system in which the continuity of the lighting depends entirely upon moving machinery. As regards the cost, he adopted for the alternating system the figures given in our article of the 2nd December, but with the modification that instead of £12 per indicated horse power he only allowed £8. 12s., thus reducing the cost of steam plant to £12,470. The buildings, chimney stack, water tanks, and all accessories were estimated at £11,000, bringing up the total cost of the station to £29,040. For the battery system he proposed a plant of similar type to that erected in Vienna. The dynamos would have to supply two-thirds of the maximum net output of 600 kilo.-watts, which, with the addition of 8¼ per cent. loss in the charging mains and 20 per cent. of reserve power, brings the dynamo output at the station up to 600 kilo.-watts or 1000 i.h.p. This plant can be divided into six sets of combined engines and dynamos, each of 100 kilo.-watts, and the total cost of the station, allowing £8,000 for buildings, &c., comes to £21,500. In estimating the cost of alternating transformers, Mr. Crompton rejects Mr. Kapp's proposal to lay down a network of low pressure distributing mains, and feed this by a few large transformers, on account of the difficulty of providing space for these transformers, and

he assumes that small transformers would have to be used, one to every two houses. The cost of these was estimated at £7,500. The accumulators to be used as transformers must be of sufficient capacity to supply 200 kilo.-watts for the hours during which the demand exceeds the 400 kilo.-watts supplied by the dynamos. The author therefore provides four groups of accumulators, each of which has a total capacity of 259 kilo.-watts and a storage sufficient for five hours of extreme demand. In order to meet a possible interruption in the charging current, which, however, need only last a short time, as spare machinery would be provided, the accumulators should be capable of being discharged without damage to themselves at the rate of 650 kilo.-watts, and it is this latter requirement which has so long delayed the introduction of accumulators for central station lighting. Too much attention has been paid to the capacity and too little to the rate of possible maximum discharge. The author, however, considers this state of things now remedied, and he has been told that there are several makers who can supply accumulators which will give an exceptionally large maximum discharge without being damaged. He estimates the price of the batteries, consisting of 240 cells in series, inclusive of stands, at £9,600. Sub-stations, which contain the battery transformers, can be placed on mews property within 300 yards radius of the houses to be lighted. The sub-station would consist of a battery room and a living room for the man in charge. The cost of the central station for both systems is given in Table III.

The last section of Mr. Crompton's paper dealt with the working expenses and the cost of maintenance in both systems. He assumed the same commercial efficiency of 75 per cent. from the i.h.p. to the electrical output for both the continuous and alternating current plant when working at full output; but whilst allowing 80 per cent. efficiency from the output at the dynamo terminals to the power delivered to the lamps when batteries are used, he only allowed 70 per cent. efficiency for the transformers during the time of maximum supply, and less than 30 per cent. for the remaining twenty-one hours during the day. During that time he estimated the efficiency of the generating plant at only 50 per cent. for the alternate current system, so that the total efficiency from the i.h.p. to the energy delivered to the consumers' lamps would only be 15 per cent. The items of labour also tell in favour of the battery system, and we give below Table IV., which gives the estimate of the working and maintenance expenses in detail.

In conclusion, Mr. Crompton pointed out that whilst the battery system admits of an increased sale of current by simply working the engines for longer hours, but without any increase in the plant, the transformer system does not admit of an increase in output without a proportionate increase of the plant.

The discussion was opened by Mr. Kapp, who congratulated the makers of storage batteries upon the extremely able way in which Mr. Crompton had advocated these appliances. The paper they had just listened to could not fail to greatly increase the confidence of users and suppliers of the electric light in batteries, and would give considerable stimulus to this industry. He thought that Mr. Crompton's estimate of an average sale of 2100 units per day was fairly representative of the London load diagram; but if they looked to the load diagram of Boston or Cincinnati, they would find that the estimate of the writer in *Industries*, which was for 3600 units, was nearer the mark. Referring to the cost of mains, the speaker thought Mr. Crompton had rather over-estimated the cost of laying insulated mains, as with lead covered cables no culvert, channel, or trough, nor filling in with bitumen or cement, was required, and on this account the difference of price between the insulated mains and the author's bare copper mains would not be so great as represented in the tables. On the other hand, lead covered cables can now be obtained with an insulation resistance of several hundred megohms per mile, whereas Mr. Crompton's mains would necessarily have a much lower insulation, and the speaker did not think it wise to sacrifice high insulation for a comparatively small difference of price. Regarding the difficulty of using underground mains for currents of high pressure, the speaker alluded to the fact that such cables have been in use with perfect success for over two years at Milan, under pressures varying from 1200 to 2000 volts, and in the latter case with alternating currents, so that there was no insurmountable difficulty in laying down an underground high pressure system. It would, however, be well to have the high pressure mains as short as possible, and on this account his own plan of using high pressure cables as feeders only, and of distributing by a network of low pressure mains, was preferable to the plan suggested in Mr. Crompton's paper, where the whole 22,000 yards of double main were under high pressure. For a supply system of the size referred to in the paper, the speaker would instal ten feeding centres, each consisting of a transformer capable of maintaining from 1000 to 1200 lights, and according to the demand all the ten

Digitized by Google

or a smaller number of transformers would be used. By this means it would be possible to work each transformer with a reasonable output, and at a very high efficiency. He thought the author's estimate of an efficiency of 70 per cent. was purely conjectural. Professor Ayrton's experiments had shown that when the output fell to one-third, the efficiency of the transformer was still 85·8 per cent., and even with an output of only one-fifth of the full load, the efficiency was 80 per cent. These considerations would reduce the working expenses of the alternating current system. On the other hand, the speaker thought that the working expenses of the battery system had been over-estimated by the author, who allowed only four feeding centres for the whole of the district. With mains one quarter of a square inch in section, it would be impossible to keep the variation of pressure within the limit of 2 or 3 per cent., which is essential in order to satisfy the just demands of the householder for a light of constant brilliancy. It would therefore be necessary to have heavier mains or more feeding centres. If they compared Mr. Crompton's proposal with the installation for Bradford, which had recently been designed by Mr. Shoolbred, they would find that Mr. Shoolbred, who was using mains of ·177 sq. in. section, had provided for a supply of 1000 lamps from each feeding centre. With mains of the author's section, the supply might be increased to 1400 lamps. It must also be remembered that in Mr. Shoolbred's installation at Bradford, full advantage could be taken of cross connections in the network which would relieve those portions of the mains which are heavily loaded, whereas, on Mr. Crompton's plan, such cross connection would be inadmissible, because the five wires were each at a different potential. Allowing then for the loss of conductivity by the want of cross connections, the speaker thought that to obtain an equally satisfactory distribution as that designed for Bradford, the author would, with ¼ sq. in. mains, have to employ at least ten battery feeding centres, instead of four. He would therefore have to allow an additional £600 in his working expenses for the wages of the attendants at six additional battery centres; or, if he wished to save this item, and to retain only four battery centres, he would have to employ mains of 1½ sq in. section, costing £20,000 more than estimated. In this case, the working expenses would have to be increased by about £1,500 on account of maintenance. The speaker also drew attention to the fact that Mr. Crompton had not allowed in his working expenses anything for the rent of the localities where his battery centres were to be established. Since they must necessarily be near the houses to be lighted, the rents would be rather high, and he thought that at least £500 per annum should have been added to the working expenses on this account. The system proposed by the author was a five-wire system, with batteries parallel to the lamps, and the speaker asked in what manner the pressure would be regulated. They all knew that a storage cell requires about 2½ volts to charge it, whereas on discharge it would only yield 2 volts, and it would therefore be necessary either to work the lighting circuit through rheostats, as is done in the Edison central sections, or to change the number of cells coupled to the lighting circuit, so as to maintain a constant pressure there, whatever be the rate of supply. In the latter case, he wished to ask Mr. Crompton, or any other battery maker, how it was possible to obviate the difficulty of charging certain of the cells more than others.

Mr. Parker, of Wolverhampton, also dwelt upon the difficulty of regulation, and considered the standard pressure of from 400 volts to 500 volts, as adopted by the author, as too low for long distance lighting. He regretted to see that no mention had been made in the paper of the Colchester installation, with which he had been connected, having supplied the charging dynamos. The regulation adopted in this installation was fairly simple, and the reason of failure, the speaker thought, was partly due to the restricted size of the whole scheme, and to difficulties in the storage cells, which had since then been remedied. As regards the Vienna installation, he did not think this differed in principle from any private installation, as it was not, properly speaking, a central station for public supply. Mr. Parker thought that the author's estimates were fairly correct, and that central stations on the battery system might be carried out at the cost mentioned. As regards the reliability of high pressure alternating current distribution, he would draw attention to the Eastbourne installation, which has been running without any hitch and without stoppage for the last two years. The credit for this success was in a great measure due to Mr. Lowrie, the engineer in charge.

Mr. Preece considered the question raised by the author's paper as one of the greatest importance. At the present moment there were from thirty to forty corporations anxious to introduce the electric light, and wanting to take scientific advice on the subject; but consulting engineers had to delay taking their fees, because they could not make up their minds which system to recommend. The speaker might perhaps be prejudiced in favour of the battery system, as he had employed batteries for lighting his own house for several years, and had found them to answer perfectly. If the charging and discharging currents are small, he thought 90 per cent. efficiency might be obtained from a battery; but with heavy currents the efficiency might fall to 60 per cent., and the speaker thought Mr. Crompton had neglected to take account of this circumstance. Batteries require very careful treatment. The density of the liquid in each cell of his own battery is tested every morning, and each cell is inspected daily to see that the plates are clear. His present battery has been in use for two and a half years, and is now as good as ever. He has also an old Planté battery which has been used for five years, and which still appears to be in perfect condition. For these reasons Mr. Preece was inclined to think that the low depreciation of 10 per cent. adopted by the author is admissible. There are various reasons in favour of either system. If it were a question of efficiency only he would be inclined to prefer the alternating current transformer; but batteries have the great advantage of providing a store of energy, so that an interruption of the service at the generating station, or damage to the charging mains when taking up the streets, would not put the houses into darkness. The speaker thought that the voltage adopted by Mr. Crompton was too low, as it did not admit of long distance supply. Electrical engineers were at the present moment debating the famous clause of the new Electric Lighting Bill, under which the station might be bought up without any allowance for goodwill by the local authorities after forty-two years. If, however, the supply were on a high pressure system, the generating station could be placed outside the radius over which the local authorities for the district lighted have command, and in that case it would not be to their advantage to compulsorily acquire the distributing plant, because they could not work it without at the same time buying the generating station, to which the compulsory purchase clause does not apply. High pressure and long distance distribution would give therefore to electric light contractors the power to resist this compulsory purchase, which they all regard as objectionable. Mr. Preece had not completed his remarks when the meeting was adjourned till the 19th inst., at which time he intends to re-open the discussion.

GOVERNMENT TESTS OF THE STRENGTH OF SPIRITS.

On the 9th inst., at a meeting of the Society of Chemical Industry, Dr. B. Derham read a paper on "Defects in the Method of Charging the Duty on Spirits," one of the chief points in which was that it is an erroneous assumption that at every degree of temperature the same relation of strength to the gallon of proof spirit at 51°F. is preserved. One hundred gallons at 51°F. expand to about 101 gallons at 80°F., yet under the present system each of these 101 gallons is assumed to be of the same strength as at the lower temperature, whereas it contains less spirit. At temperatures below 51°F. each gallon contains more spirit; hence the tables compiled by Sikes for use with his hydrometer are vitiated, and under the present system of Government testing there is a gain to the Revenue at temperatures over 51°F., and a loss at temperatures under 51°F. The authorities suppose these two errors to about balance each other; but this is not so. Taking even the South of England, the mean temperature of Greenwich is 49·1°F.; at Liverpool and Manchester it is 47°F., and at Inverness about 45°F.; it is 41°F. in Scotland during the nine cooler months of the year. About two-thirds of the whole store of bonded spirits are warehoused in Scotland, and the remaining one-third in England. He believed 46°F. to be the mean temperature of the spirits stored in the United Kingdom, and because of the errors he had pointed out he calculated that the Revenue lost at least £50,000 a year by its method of testing with Sikes' hydrometer and tables.

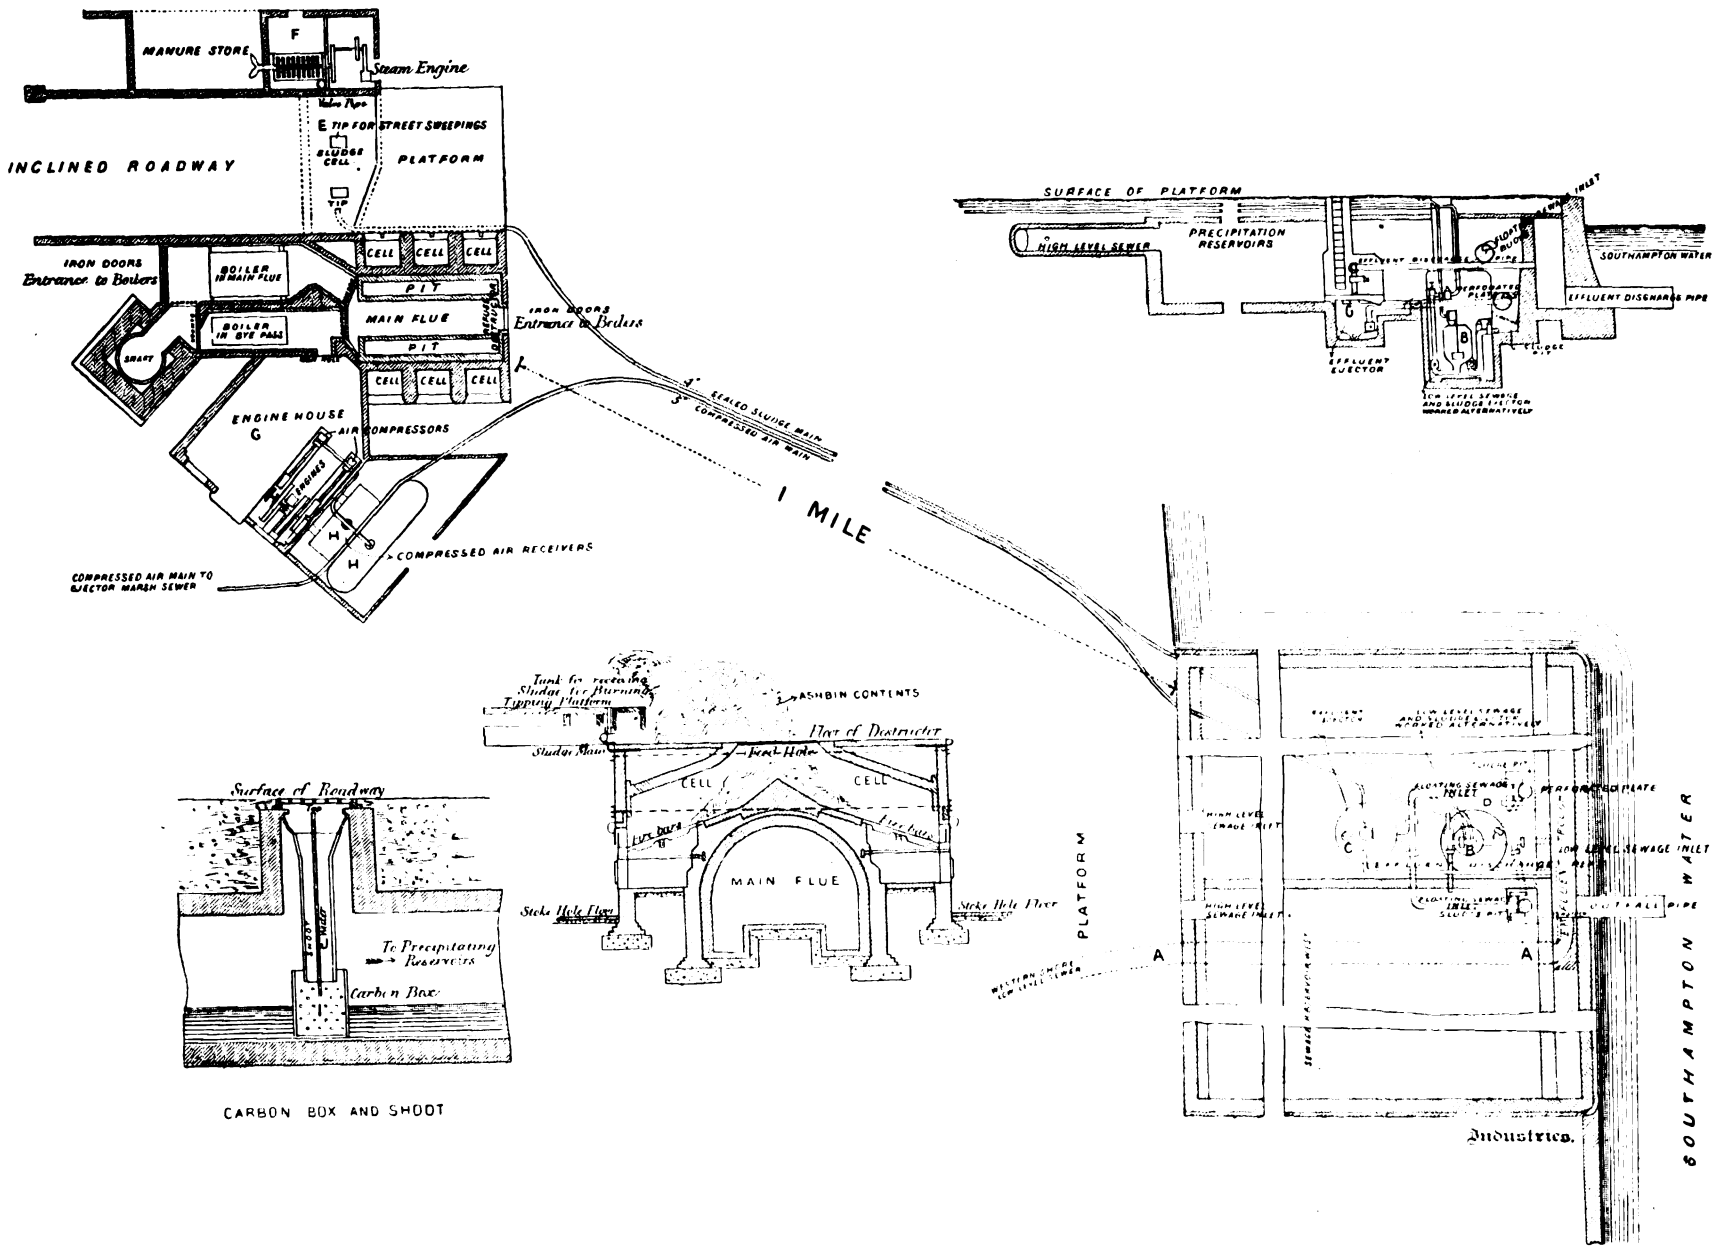
Mr. David Howard, the chairman, was in favour of the present system of calculating by proof gallons. It might be an unscientific standard, but it was convenient and practical.

Mr. Keen had long been in the Customs service, and had found that the system of gauging was such that in calculating the contents of a cask of 130 gallons it is easy to make a mistake of four or five gallons, of which latter the merchant gets the benefit after sending the rest to be methylated, there being a tendency to conclude in his favour all doubts about measurement. The kind of hydrometer required is one easy to use, not liable to get out of order, and one fit to be handled by day or night by a class of men not well paid. Sikes' hydrometer meets these requirements fairly well, although its tables are doubtful. Most spirits do not pay duty at much above proof; in Scotland it is 11 over proof, and that reduced Dr. Derham's estimate of £50,000 loss. At one time account was not taken of saccharine matter in spirits; but one of Mr. Gladstone's governments began the separating of the spirit from the saccharine matter, and charging duty on it at its real strength, with a gain to the Revenue of £180,000 a year.

Mr. Helm remarked that Sikes' hydrometer is infinitely superior to Dr. Derham's, because it can be used by all kinds of people not very highly educated, and has fewer figures on it. Besides, it has less wearing surface, so will not so frequently require re-adjustment. The authorities have satisfied themselves that they lose nothing by the hydrometer being standardised at 51°F., and he knew that Dr. Derham's figures about the temperature of warehouses were all conjectural. For instance, the mean temperature in warehouses in London is nearer 55°F. than 46°F. If only £50,000 be lost over the immense quantity of spirits consumed in these islands, he thought it a very satisfactory result, considering the low pay of the officers employed.

Professor Dewar said that Dr. Derham's main argument was for more scientific accuracy in testing, and commercial points were of a secondary nature. Still, if the Government could save £50,000 in the way pointed out by Dr. Derham, he wished that they would give some or all of the amount to provide decent alcohol at a moderate price for use in the laboratories of the scientific chemists of this country, who in this matter are heavily handicapped as compared with the position of their brethren in Continental Europe. A Russian chemist has recently proved that at certain different temperatures of diluted spirit, different hydrates of alcohol are formed, and has succeeded in separating them from each other.

Dr. Derham did not see why errors due to gauging should be brought forward as an argument against rectifying errors due to testing. He did not know about the average temperature of London warehouses, but possessed exact information about the temperature of warehouses in the Midland Counties, and in Scotland.



THE WIMBLEDON SEWAGE DISPOSAL WORKS.

At a meeting of the Society of Engineers, held on the 9th inst., a paper was read on the above subject by Mr. W. Santo Crimp, Assoc.M.Inst.C.E., F.G.S. The author stated that the population of the district at the present time was about 25,000, and its area 3220 acres, 640 acres of which form the Wimbledon portion of the common. Three main outfall sewers had been constructed for the drainage of the district; the sewage from one of them requires to be pumped, whilst that from the other two gravitates to the Sewage Disposal Works. Several miles of sewers were in existence at the period when the works described were commenced, and these were retained for the disposal of the surface water. The works have been largely added to by the author, and a new outfall for the western portion of the district constructed. Concrete tubes have been largely used. All the roads now made up under the 150th section of the Public Health Act are provided with duplicate means of drainage, and the entire scheme offers a good example of the "separate" system. The works designed by the author for remedying the defective portions of the low level outfall consist of a pumping station and about two miles of new outfalls, situated in the western part of the district. The new western outfall was constructed sufficiently deep to admit of all the building land in that part of the district being drained. The pumping station is provided with pumping machinery in duplicate, operated by a pair of "Otto" gas engines. The sewage is lifted into a large tank holding nearly 20,000 gallons, which, when full, discharges its contents into the 18in. outfall, which is thus effectively flushed at least twice daily. Five automatic flushing tanks were also constructed at various portions of the system where most required, each tank being provided with one of Field's annular syphons. The total cost of the remedial works was about £12,000. All the sewers were originally ventilated by means of open street gratings; but these have for the most part been closed, and ventilating pipes put up in lieu of them. The total sum expended by the Local Board on the main drainage works amounted to £60,000, but in addition large sums have been spent by private land owners in the construction of roads and sewers, for the purpose of developing their estates; so that the whole of the main sewers of the district have cost not less than £100,000.

The author then described the main pumping station and machinery, and the six settling tanks for the reception and precipitation of the sewage from the mid and low level outfalls, arranged to work either on the continuous or separate system as desired. The sewage is treated with milk of lime and sulphate of alumina in the proportion of eight and six grains per gallon respectively. The solids are precipitated and the effluent water is then conducted over the farm, which is seventy-three acres in extent. In very hot weather a little permanganate of potash is also used. The normal sewage flow is 750,000 gallons per day. The precipitated solids are dealt with by means of filter presses, three of which presses are now employed. Experiments made with this sludge prove it to be of slightly higher value as manure than ordinary stable manure. The farm, as originally laid out, consisted of forty-seven acres of somewhat clayey land, but a further area of twenty-six acres has since been added. There are also three filters of burnt ballast, having an aggregate area of two and a half acres, and a depth of three feet, for the treatment of storm waters. Great care is taken in applying the sewage, so as to prevent any of it finding its way direct to the subsoil drains. The principal crops grown on the farm are rye grass, mangolds, and osiers. The total receipts for produce for the year ending 25th March, 1888, was £20 per acre, and the inclusive working expenses were about £12 per acre. After deducting the profit on the farm, the net annual cost of pumping, deodorising, and purifying the sewage, including all expenses, is £3,690, equal to a rate of 6·15d. in the pound.

THE SOUTHAMPTON SEWAGE WORKS.

THE SOUTHAMPTON SEWAGE WORKS.

The utilisation of waste products is a distinctive feature of modern industry, and many substances which twenty or thirty years ago were regarded as an absolute nuisance to be got rid of at any cost, are now collected, stored, and subjected to manufacturing processes of which the previous generation knew nothing. The importance of such processes was recognised as long ago as 1873, when at the Vienna International Exhibition a special group of exhibits was set apart to illustrate the various ways in which waste products might be utilised; but the exhibits referred mainly to such waste products as are obtained by the manufacturer in his industrial operations; and in this direction industrial development, stimulated by keen competition and low prices, has within the last decade been very remarkable. There are, however, other kinds of waste products which do not lend themselves readily to any useful art, and which, nevertheless, must be disposed of, and the mere disposal of which taxes the resources of the sanitary engineer to the utmost; but if the process of disposing of such matters as sewage, street sweepings, and the contents of the domestic dust bin is accompanied by a manufacturing process yielding useful substances in return for objectionable matter, it will be admitted that the sanitary engineer has achieved perfection in the art of utilising waste products. This result has actually been attained by Mr. W. B. G. Bennett, the borough surveyor of Southampton, at the destruction and sewage clarification works of that town.

Although the works in their present form were planned about two years ago, and some particulars of the utilisation of sewage sludge and dust bin refuse as carried on in Southampton, Wimbledon, Ealing, and other places were brought before the Institution of Civil Engineers about a year ago, and discussed with the heat and vigour so characteristic of sewage doctors, the engineering profession generally have hardly paid to these improvements the attention they deserve; and it was only after Mr. Bennett had the brilliant idea of utilising the waste heat energy of his destructors for electric lighting, that public attention was directed to the subject. We call this idea brilliant because it appeals to the imagination. What could be more seductive to the British householder than the prospect of getting a soft, white, and healthy light in return for the contents of his dust bin? Here was a way to get motive power gratis, and therefore the great obstacle to the introduction of the electric light into our houses, viz., the cost, had now been overcome. Thus argued many persons unacquainted with the real nature of electric light supply business; but the argument is fallacious. In the first place the amount of heat available is insufficient for electric lighting on a large scale, and in the second place the saving in the coal bill would not compensate for the disadvantage of having the electric light station dependent upon some other works for power. It must not be forgotten that the cost for fuel is only one of the items in the general cost of supplying electricity; it may reach perhaps 20 or even 30 per cent. of the total expenditure, and to secure this small advantage the electric light station would have to sacrifice its independence and, to a large extent, the ability to vary the output simultaneously with the demand. The supply of electric light or power is a hand to mouth business, and unless the boilers, engines, dynamos, and all necessaries are under perfect control, it will be found impossible to comply with the ever varying demands of the subscribers. In making these remarks, we do not wish to detract in any way from the value of the experiment in electric lighting made by Mr. Bennett, which has conclusively shown that any surplus heat from the destructors can be used to supply power for a small electric light installation; but this does not prove that large central stations can be worked on this plan.

With the above limitation, we welcome Mr. Bennett's plan to obtain electricity as a by-product in sewage works as a distinct impovement, which is likely to be adopted by other local authorities, and we give below a description of the electrical plant in use at Southampton. To render our description intelligible, we must briefly allude to the works as a whole, by the aid of the plan shown above, for which we are indebted to the courtesy of Mr. Bennett; and for a detailed description of these works and the process of treating town refuse there carried on we would refer our readers to the "Minutes of Proceedings of the Institution of Civil Engineers," Vol. XCI., which has just been issued, and which contains, amongst the selected papers, one by Mr. Bennett, on the "Southampton Sewage Clarification and House Refuse Disposal Works." The works deal with about 500,000 gallons of sewage daily, coming from a district containing 13,000 inhabitants, and with the whole of the dust bin contents and street refuse of the borough, amounting to about 70 cart loads per day. The carts are brought up an inclined platform at the Chapel Wharf, and their contents are discharged into hoppers above one of Messrs. Manlove, Alliott, Fryer, & Co.'s refuse destructors, with six cells or furnaces, each able to deal with from eight to nine tons of dust bin contents per day; and the products of combustion pass through a main flue into one of two flues containing each a multitubular steel boiler—one of 30 h.p., and the other of 10 h.p. These boilers can be cleaned alternately, suitable dampers being provided for shutting off either flue. The necessary draught is obtained by a chimney 160ft. high, not shown in the plan. The steam from the boilers is used for working an air compressing engine G indicating 31·5 h.p., and the compressed air is stored in the reservoirs H. There is also a small steam engine driving the incorporator F, for mixing road sweepings and sewage sludge for manure, which is sold to neighbouring farmers at 2s. 6d. per load. The sewage is clarified in two reservoirs at the Southampton Water, about a mile

Digitized by Google

distant from the works at Chapel Wharf, the precipitation being effected by porous carbon mixed with sulphuric acid and water into a stiff paste, and led through a shoot J into the perforated box I placed into the sewer, a small jet of water preventing consolidation. At the reservoirs there are two of Stone's ejectors, the air supply being by a 5in. main from the engine house; one of the ejectors has 360 and the other 700 gallons capacity. The object of installing the ejectors was to render the discharge of the effluent independent of the tide, and to force the sludge back to the incorporator through a 4in. main. The details of the arrangement will be understood from our diagram.

The electric light installation, which was put down by Mr. A. I. Baron, comprises a 10 kilo.-watt Gülcher dynamo, twelve glow lamps of 16 c.p., and four 3000-candle arcs, representing a total output of about 75 ampères at 65 volts pressure. The dynamo is worked from the main engines G, and speeded at 820 revolutions per minute. The glow lamps are fitted in the office, engine house, and wheelwrights' shop, &c., and the arc lamps are placed in the yard, over the main gate, and on the wharf. Mr. Baron estimates that the present boilers at the works could work up to 110 i.h.p., of which 60 i.h.p. would be at all times available for electric lighting. By putting down a separate engine this power could be utilised at night for street lighting by arc lamps, and during the day for charging storage batteries, from which a limited district could be supplied with incandescent light.

THE GRIFFIN GAS ENGINE.

Comparative Table of the more important Results of Tests on an 8 n.h.p. Griffin Gas Engine obtained independently by Professor Kennedy, of University College, London, and Professor Jamieson, of the Technical College, Glasgow.

Table of the More Important Results.	Brake Tests.		Electrical Tests.	
	Kennedy.	Jamieson.	Kennedy.	Jamieson.
1. Average mean pressure during working stroke in lbs. per square inch	56·71	64	59	63·2
2. Revolutions of engine per minute	223·8	183·6	210·4	187·7
3. *Indicated h.p. from working stroke diagrams*	18·62	17·28	18·26	17·4
6. Mean net brake load in lbs.	126·4	140·0	...	...
7. Mean radius of brake load in feet	2·775	2·78	...	...
8. *Brake h.p.*	14·94	13·6	...	...
9. *Electrical h.p.* (effective found in external circuit)	...	...	10·3	9·74
10. Ratio of brake h.p. to indicated h.p. (working stroke)	80·2 %	18·7 %	...	...
11. Ratio of electrical h.p. to indicated h.p. „	...	...	56·4 %	55·9 %
12. *Gas used per indicated h.p. per hour in cubic feet*	18·92	19·27	18·87	19·13
13. *Gas used per brake h.p. per hour in cubic feet*	23·58	24·48	...	...
14. *Gas used per useful electrical h.p. per hour in cubic feet*	...	...	33·4	34·2
15. *Percentages of the whole heat of combustion*—				
Converted into indicated h.p.	20·0 %	19·2 %	...	...
Carried away by jacket water	37·6 %	30·4 %	...	...
Discharged in exhaust, blank charge, &c	42·4 %	50·4 %	...	...
Total	100·0	100·0	...	...
16. Equation to the actual expansion curve	$p v^{1\cdot373}$	$p v^{1\cdot382}$	...	...
„ expansion curve from ratio of specific heats	$p v^{1\cdot384}$	...	...	...
„ actual compression curve	$p v^{1\cdot262}$	$p v^{1\cdot4}$	...	...
„ compression curve assumed same as air for air	$p v^{1\cdot408}$	...	...	...

Notes.

COLZA OIL

The British Vice-Consul at Caen reports that the cultivation of colza, which a few years ago was very extensive in his district, appears to be gradually dying out altogether, though it was formerly the mainstay of the farmer, to which he looked forward to paying his rent. Colza is now meeting with very little demand, owing to the introduction of cheap mineral oils for lighting purposes. Colza oil was also extensively used for lubricating machinery, but it is now superseded by heavier and cheaper oils.

THE AMERICAN CANALS.

In considering the question of the Panama Canal, the *Engineering News* of New York expresses the opinion that even if M. de Lesseps should die with his task incomplete, and the entire work were abandoned by its present promoters, there should be no difficulty in re-organising it on a new basis; but it would probably always remain a lock canal. Our contemporary also states that the Nicaragua Canal surveying expedition will probably not return as a body, as some of the members will be employed in the construction of the canal, which will follow closely upon the completion of the survey. The first work will be to build a wharf at Greytown, at which to land the necessary plant.

ENGLISH CAPITAL IN SPAIN.

Our Madrid correspondent has on various occasions pointed out cases in which English capital might be advantageously employed in Spanish industries, and Consul Woolridge, of Barcelona, in a Foreign Office report, also draws attention to this subject. He says that Spain is rich in raw materials, and that Englishmen could manufacture articles there which would be quite as good as if they were manufactured in England, whilst the wages which would have to be paid would be less. The Consul complains in general terms of the want of enterprise which is shown by English manufacturers and exporters in meeting the competition of other countries in Spain.

EXHIBITION IN ROUEN.

It is proposed to hold in Rouen, from the 20th of May to the 20th of June next, a hygienic exhibition, at which lectures will be given by the most competent French hygienists. The idea of holding this Exhibition was suggested to the town authorities of Rouen by the Normandy Society of Practical Hygiene, which is under the patronage of the Minister of Commerce and Industry. The object of the Exhibition is to bring under the notice of those interested in sanitary appliances, and to give them an opportunity of examining, the best apparatus and the most perfect models which should be adopted for the sanitation of public and private dwellings, workshops, and towns. The exhibits should exemplify the best methods of supplying light and air to dwellings, also their ventilation, heating, artificial lighting, cleansing, disinfecting, also the drainage and removal of night soil, and the various means to be taken to prevent the spread of contagious diseases. Models will be on view of artisans' dwellings, night refuges, and mortuaries. All communications respecting this exhibition should be addressed to the president of the Normandy Society of Practical Hygiene, 7, Rue Jeanne d'Arc, Rouen.

THE GRIFFIN GAS ENGINE.

In our last issue we published a report by Professor Jamieson, of Glasgow, on this engine, and we have since received a copy of a report by Professor Kennedy, of London, on the same engine, given quite independently, and with his own apparatus and by his own methods. We have taken the trouble to extract from each report the more important results for the full brake and electrical horse power tests, and now place them before our readers in the above table, so that they may see at a glance any differences or discrepancies, as well as to enable easy comparison with tests of other gas engines. In the brake horse power tests Professor Kennedy has evidently made the very most of the engine's capabilities, for he has run it at a considerably higher speed and with a lighter brake load than Professor Jamieson did; yet, nevertheless, the more important final results, such as the gas consumed per indicated brake and electrical horse powers, as well as the several efficiencies of the engine, are remarkably close, seeing that the results were arrived at by different observers, and in several cases by different methods and apparatus. Professor Kennedy finds the absolute efficiency of the engine (or the ratio of the indicated horse power to the total possible calculated heat of combustion) to be 20 per cent., while Professor Jamieson makes it out to be 19·2 per cent. These are excellent results, and obtained by independent and able experimentalists. Messrs. Dick, Kerr, & Co. certainly deserve to be congratulated upon their perseverance and skill in bringing the Griffin engine up to its present perfection.

THE POLLUTION OF AIR AND WATER BY CHEMICAL WORKS AND MANUFACTURERS.

At the ordinary meeting of the Society of Arts, held on the 11th inst., Mr. Alfred E. Fletcher, H.M. Chief Inspector of Alkali Works, read a paper on "Legislation Concerning the Pollution of Air and Water," in which mention was made of the hurtful gases thrown off during the preparation of chemicals used in the bleaching of cotton and wool, the preparation of paper, the dyeing of cloths, the smelting of metals, and many other such operations. In 1863, the first Act was passed compelling the condensation of the hydrochloric acid liable to be thrown off from alkali works. This was followed by a second Alkali Act in 1874, and a third in 1881. Several other chemical trades are placed within the scope of this last Act. In all 1060 works are registered under it. The method of working the Act by means of a chief inspector and district inspectors was described, and the success attending their work referred to. The manufacturers, at first alarmed, now welcome the inspectors as being an assistance to them in saving material which, though valuable, caused great nuisance when allowed to escape. The nuisance arising from black smoke was dealt with, and shown to be in nearly all cases curable. No less than thirteen Acts of Parliament were mentioned, dating from 1845 onward, in which the emission of black smoke is prohibited under heavy penalties. Yet the offence is continued. The reason why the law is so sparingly enforced is because its administration is in the hands of the local authorities, who themselves are often chief offenders. The smoke from private houses was also referred to, and a method of heating described which would increase the comfort of our homes and wholly prevent smoke. Reference was made to the thermometer of Mr. Hargreaves and Mr. Mond's gas producer, both being arrangements useful in effecting the combustion of coal without causing smoke. In 1876, a Rivers Pollution Prevention Act was passed. That also has been inoperative from the reason that its working is left in local hands. Some weak points in it were pointed out. If slightly modified, and placed in the hands of an inspector and district inspectors, a like success might be expected as has attended the working of the Alkali Act.

CHEMICALS IN FRANCE.

In reporting on the trade of Rouen during 1887, the British Consul at that port states, that though little business was done in chemicals, prices were maintained. Ammoniacal produce advanced in price, and nitrate and nitric acid rose 10 per cent., owing to a better demand for agricultural purposes. Colouring matter and pyroligneous acid and soap remain the same. The rise in volatile alkalies continues, on account of the orders from the South of France, as a preventive against the mildew in the vines. In the third quarter of the year a rise occurred in sub-products of wood, and a further improvement took place at the close of the year. The arrangement between the large manufacturers has kept up the price of bicarbonate of soda, and the increasing demand for chemical manure has caused a change for the better. The situation of the trade generally is favourable.

EXHIBITION IN ATHENS.

It is proposed to hold in Athens during the latter portion of October and the beginning of November a national industrial exhibition, to which foreign exhibits will also be admitted. This will be the fourth national exhibition held in Greece, and its object is to develop native industries. It is expected to be a great success, since the festivities in connection with the celebration of the twenty-fifth year of the reign of King George, which will take place simultaneously, will attract a considerable number of people to Athens. The undertaking has been placed under the protection and management of the Government. Those Greeks residing abroad will be permitted to take part in the Exhibition, whilst exhibits from foreign countries will be admitted, but not allowed to compete. These exhibits may comprise agricultural and manufacturing machinery, apparatus and tools which are already in use in Greece, or whose introduction would assist in the development of native industries; also inventions of all kinds. These objects will be installed in pavilions, the cost of erection of which exhibitors will have to bear, as well as the expenses connected with the insurance and superintendence of exhibits. The Exhibition will be held in the new building Zappion, so named after its founder. The Government have taken no steps for reducing the cost of transport on foreign goods, nor the Customs dues, and it is stated that they have no such intention. From the above it will be seen that the expenses which foreign exhibitors must incur at this Exhibition will be somewhat heavy.

Patent Record.

Compiled from "The Official Journal of the Patent Office," by W. E. Heys, *70, Market-street, Manchester.*

APPLICATIONS FOR PATENTS.

(The names in italics within parentheses are those of Communicators of Inventions.)

ENGINEERING.

6th April, 1888.

5105. Twigg & Turner..... Governing the speed of engines.
5115. Crowther, S. ..... Washing and scouring fabrics.
5116. Willis, J., & others..... Anti-corrosive steel propeller blades.
5117. Naughty, A..... Two-wheeled vehicles.
5122. Devis, E. C. J. ..... Moulding metal plates.
5135. Breadner, E. ..... Apparatus for damping woven fabrics.
5146. Mannesmann and Mannesmann..... Manufacturing toothed pinions.
5147. Mannesmann and Mannesmann..... Rolling metallic hoops.
5148. Mannesmann and Mannesmann..... Moulding tubes.
5149. Hassel, W..... Manufacture of scythe blades.
5150. Mills, B. J. B. ..... Brakes (*Guetton-Dangon & Des Georges*).
5151. Fell, J. C..... Mechanical cleaners for internal parts of boilers (*Bower*).
5152. Templeton & Schischkar..... Facing and flanging machine.
5153. Templeton & Schischkar..... Boring machine for pedestals.
5154. Wallace, J. S..... Sewing machines.
5157. Shapton, W..... Apparatus for shipping coal.

7th April, 1888.

5160. Hamblin, S. J. ..... Rotary engine.
5161. Peake, W..... Breech mechanism for battery guns and ordnance.
5163. Knowles & Whittaker Machines for printing fabrics.
5167. Thorp, T. ..... Automatic reciprocating fluid engine.
5172. Lang, J., & others..... Machines for cutting the teeth of racks.
5174. Bey, A. S. E..... Quick-steering ship rudder.
5184. Rittershausen, M..... Sack sewing machines.
5185. Allen, J. ..... Stuffing the tubes of surface condensers.
5188. Dodd, F. W. ..... Governor.
5190. Beck, W. H. ..... Jacquard cards (*Carbonelle*).
5199. Nisbet, W..... Colouring waterproof materials.
5202. Unwin, F..... Dabbing brushes of combing machines.
5204. Lake, H. H. ..... Ignition apparatus for gas engines (*Benggyer*).
5206. Ellis, O. J. ..... Motive power engines.
5207. Haddan, R. ..... Kneading machines (*Barenys*).
5209. Welch, S. S..... Steam engines.
5213. Cox, R. ..... Polishing glass and marble.

9th April, 1888.

5218. Shaw, H. ..... Automatic disengaging lever for starting engines.
5220. Stout, C. ..... Indicating the flow of water in pipes.
5223. Allen & Bowers..... Purifying water for boilers.
5225. Gregory, W. G. ..... Counterbalancing centre boards by means of springs.
5226. Hind, A..... Pattern designs for textile fabrics
5228. MacLaine, A. ..... Heating feed water.
5229. Murray, J. ..... Gutters for corrugated roofing.
5230. Watts, J. W..... Knitting machines.
5231. Mackay, F. N. ..... Combined motor & refrigerator.
5232. Seggie, A. H. ..... Printing machines.
5239. Kirk & Brook..... Card cylinders of loom dobbies.
5240. Hague, W..... Protecting boiler tubes.
5244. Mauser, P. ..... Breech loading fire arms.
5246. Breze, J. H..... Apparatus for condensing, cooling, and heating fluids.
5249. Hay & Grocock ..... Self sustaining hoists.
5251. Smith, H. J. ..... Moulds for casting.
5252. Hall, J..... Manufacture of leather.
5256. Williams & Hydes..... Washing engine waste.
5257. Glade, C. ..... Stopping steam engines from different parts of a factory.
5263. Woolnough, G. ..... Steam boilers.
5264. Nordenfelt, T. ..... Gun mountings.
5265. Wilcox, R. ..... Operating torpedoes.
5266. Mellor & Chadwick... Circular knitting machines.
5267. Davidson, J..... Manufacture of paper.
5274. Marcet, A. ..... Production of cold by the expansion of compressed air.

10th April, 1888.

5276. Leavitt, F. M..... Drop hammers.
5277. Paget, A. ..... Warp machines.
5288. Buckton & Buckton ... Automatically regulating the pressure of water in mains.
5290. Raymond & Raymond... Couplings for railways.
5293. Martin, B. D. ..... Manufacture of chill rolls.
5296. Aitken, H. ..... Generating steam.
5298. Gordon, J. ..... Safety hoist doors.
5300. Fry & Fry ..... Paddle propeller.
5301. Thompson, W. J..... Looms.
5309. Nichols, M. L..... Grain binding harvesters.
5310. Thompson, W. P..... Multiple cylinder motors (*Benham*).
5325. Lake, H. H. ..... Manufacture of cut nails (*McKay*).
5326. Lake, H. H. ..... Washing machines (*Schumpe and Hammelrath*).
5332. Haddan, H. J. ..... Portable bridges (*Herbert*).
5335. Binns, L. ..... Spinning and twisting machines.
5336. Preble, J. Q. ..... Weighing machines.
5338. Abel, C. D. ..... Treating textile fabrics with steam (*Koethe*).
5339. Bradbury, C. ..... Lifting doors (*Grimme, Natalis, and Co.*).
5342. Kirkaldy, J..... Heating feed water.
5343. Taylor, W. ..... Spinning, twining, and hanking.
5344. McDougall & McDougall ..... Boilers.
5348. Titt, J. W. ..... Wind engines.

11th April, 1888.

18037. Lake, H. H. ..... Universal shaft couplings (*Robes and Haskell*). (Received 11th April, 1888. Ante-dated 14th November, 1887, under International Convention.)
5352. Baines & McCulloch... Automatically controlling pneumatic pumps.
5353. Hall, J..... Wheels.
5355. Nicholas, T..... Moulding boxes.
5357. Wallis & Wallis ..... Steam and other motors.
5366. Hawthorn & Liddell.. Ironing, mangling, and finishing apparatus.
5377. Croom, J. M. ..... Lubricators actuated by electro-magnets.
5379. Rowland, G. ..... Steam boilers.
5380. Butterworth, J. ..... Pointing the wires employed in the manufacture of card clothing.
5381. Haigh & Green ..... Rudders.
5382. Haigh & Green ..... Signalling between and on navigable vessels.
5385. Black, J. M..... Number printing machines.
5386. Twynam, T. ..... Manufacture of ingot iron and steel.
5391. West, D. K. ..... Baling presses (*Thornton*).
5394. Mewburn, J. C. ..... Gig mills (*La Société Grosselin pere et fils*).
5395. Shepherd, J. W., and others ..... Carding engines.
5402. Mills, B. J. B. ..... Ships' propellers (*Bidauld*).
5406. Wyman, H. ..... Wool combing machines.
5407. Tarrillion, J..... Boats.
5408. Bryan, W. B. ..... Elevating and washing sand.
5412. Stannah & Pinker..... Hydraulic hoisting machinery.

12th April, 1888.

5431. Garrs, H. de ..... Slide valves.
5437. Schaeffer & Oehlmann Lubricators.
5441. Workman, W. ..... Hoists.
5442. Battersby, J. ..... Fire bars for boiler furnaces.
5443. Mole, F. M. ..... Printing machines.
5444. Merryweather and Jakeman ..... Fire engines.
5447. Caddy, T. E..... Moulding machines.
5448. Tangyes & Floyd ..... Reversing mechanism of the slide valves of direct acting steam pumps and engines.
5453. Brin's Oxygen Co..... Bleaching (*Brin*).
5454. Vaughan, G. E. ..... Manufacture of seamless tubes (*Mannesmann & Mannesmann*).
5459. Morgan & Jeffery ... Lifts.
5460. Marres & Randall ... Cartridge marking machine.
5463. Quinlivan, T..... Steam boilers.
5468. Gastrell, J. P. H..... Rotary engines.
5469. Brandy, J..... Automatic coupling apparatus.
5471. Colley, A..... Cartridge magazine.
5472. Colley, A..... Cleaning the chamber of Martini-Henry rifles.
5473. Brown, J., & others..... Combined railway buffer and automatic coupling.

ELECTRICITY.

2313A. Ferranti, S. Z. de..... Dynamo-electrical machines. (This Application having been originally included in No. 2313, dated 15th February, 1888, takes, under Patents Rule 23, that date.)

6th April, 1888.

5110. Baraclough & Ingall. Call bells.
5127. Gisborne, J. S..... Telegraphic apparatus.
5131. Randall, C. A..... Magneto-electro storage motor.

7th April, 1888.

5162. Mordey, W. M..... Electric generators.
5182. Stone & Gilfillan..... Telegraphic transmitters.
5191. Edmunds, H..... Storage batteries.
5196. Smith, M. H..... Conducting and collecting currents in electric rail or tramway systems.

9th April, 1888.

5233. Walton, A. H..... Fusible cut-outs.
5259. Capek, J. V..... Electrical heating.

11th April, 1888.

5362. Holmes, J. H. ..... Arc lamps.
5393. St. George & Bonne ... Batteries.

12th April, 1888.

5421. Robson, W. ..... Perpetual motion and electric current generator.
5433. Preece & Andrews ... Electric matting.
5436. Nussbaum, G. A..... Automatic call box for telephonic communications.
5452. Cunnington, J. G. S. ... Fusible device for protecting electric circuits.

CHEMISTRY.

7th April, 1888.

5212. McDougall & McDougall ..... Production of solutions containing sulphurous acid or its salts.

9th April, 1888.

5270. Chardonnet, Le Vicomte H. de ..... Denitrating and dyeing pyroxyl.

10th April, 1888.

5316. Pearson, S., & others... Aluminium.

11th April, 1888.

5371. Geary, G. J..... Manufacture of sulphide of zinc (*Keiller*).
5404. Leigh, H. H. ..... Colouring matters (*Williams*).

12th April, 1888.

5461. Cross, W..... Aluminium.

MISCELLANEOUS.

6th April, 1888.

5102. Williams & Thomas..... Gas lighting apparatus.
5103. Dufty, A. ..... Manufacture of wooden bungs.
5106. Disturnal, T. J..... Apparatus for heating and drying.
5108. Hartcliffe & Malkin. Full-way valves.
5109. Hartcliffe & Malkin. Water gauges for steam boilers.
5111. Barrodale, T. H..... Protractors and rulers.
5112. Duerden, J. ..... Manufacture of paper bags.
5114. Johnson, R. A..... Spinning rings.
5123. Maconochie, A. W..... Manufacture of metal cans.
5124. Williams, J. R..... Lubricating apparatus.
5126. Kincaid, S. B..... Street lamps.
5133. McKeon & McVey..... Cork drawing machines.
5134. Browett, T. ..... Power hammers and stamps.
5136. Slingsby, G..... Securing bobbins upon the spindles of shuttles.
5144. Hurley, E. J. ..... Fixing roofing slates.
5145. Fisher & Cramp ..... Treatment of slag for road making.
5156. McNish, J. ..... Glazing paper.

7th April, 1888.

5165. Burns, D. ..... Chimney cowls.
5166. Wier, M. A. ..... Rowing carriage and velocipede.
5171. Key, J. T. ..... Miners' safety lamps.
5177. Townsend, G..... Spoke tighteners.
5179. Walker, A. H..... A sea oiling cartridge.
5180. Walker, A. H ..... Sea oiling projectile.
5187. Newton, J. M..... Producing designs in relief upon sheets of ductile metal.
5193. The Sächsische Spulenfabrik & Ginzul... Spools.
5194. Schröder & Stuart ... Lenses.
5197. Bonwick, W. P. ..... Bottle stoppers.
5203. Pontois, L. J. le..... Transmitting sounds to a distance by means of light.
5208. Herzfeld, J. ..... Gas burners.
5214. Gooch, W. D., & others. Porous artificial stone.
5215. Aird, D. A. ..... Measuring taps.

9th April, 1888.

5217. Brooks, S..... Fastener for belts.
5219. Bratby & Hinchcliffe Reducing valve.
5222. Bishop, W. ..... Lenticular glasses of lamps.
5227. Foulston, G. J. ..... Preparation for protecting bright metallic surfaces.
5234. Wenger, A. F..... Colour mixers.
5235. Fletcher, S. H. ..... Taps.
5247. Pennefather & Dinsmore ..... Ventilators.
5253. Beer, F..... Improved plastic composition for moulding.
5255. Newell, C. L. ..... Lamps.
5260. Hart, A. ..... Lamps.
5272. Halot & Avedyk..... Manufacture of aerated waters.

10th April, 1888.

5275. West, J. P. ..... Extracting the dust from corn.
5278. Brown, F..... Locks and keys.
5280. Gaskell & Gaskell ... Automatic barrel tilter.
5282. Sandon, E. F. ..... Compressing and trussing hay.
5283. Brook, E. ..... Gas producers.
5284. Morris, E. G. ..... Lamps.
5287. Evans, J. ..... Paper tubes for holding yarn.
5291. Smith, T. ..... Stoppering bottles.
5294. Partington, E. ..... Stop valves.
5295. Aitken, H. ..... Valves.
5303. Chisholm, G. ..... Tap.
5305. Petri & Hausmann..... Syphons.
5307. Gouraud, G. E. ..... Phonogram blanks (*Edison*).
5312. Thompson, W. P..... Recording thermometers (*Draper*).
5321. Restall, G. F..... Disinfecting drains.
5323. Erckel & Engelhardt Sharpening scythes.
5324. Lake, H. H. ..... Machines for lasting boots (*Lancaster*).
5327. Peters, G. M. ..... Cartridges.
5330. Gamger, J..... Maintaining circulation of liquids
5331. Haddan, H. J. ..... Gas burners (*Jackson*).
5333. Lodge, T. H..... Portland cement.
5337. Abel, C. D. ..... Supplying cooled air to rooms (*Koethe*).
5350. Godfrey & Meeker ... Chemical fire extinguishing apparatus.

11th April, 1888.

18038. Uhlenhuth, H..... Joining the ends of bands. (Received 11th April, 1888 Ante-dated 26th October, 1887, under International Convention).
5354. Bartholomew, W. ..... Crucible tongs.
5359. Bunting, S. ..... Stoppering of bottles.

Digitized by Google

5360. Siddaway & Hall ..... Shoe rivets.
5363. Hazeland, S. S. ..... Wood workers' plane irons.
5369. Wrigley, F..... Straining liquids.
5374. Gabriel, C. E. P. ..... Ball valves.
5384. Birchall, C. F. B., and others ..... Reproduction of designs upon glass.
5388. Klever & Storz..... Hose couplings.
5390. Sherrin & Sherrin ... Velocipedes.
5392. Pepys, W. C..... Thermometers.
5399. Stone, R. ..... Paint.
5400. Vale, H. ..... Gas lamps.
5405. Boutcher, A. G..... Adjustable wrench.
5409. Wern, H..... Tins.
5410. Ruck, R. M. ..... Releasing hooks or shackles.
5413. Gooch, W. D., and ors. Oil and spirit lamps.

12th April, 1888.

5418. Schmidt, W..... Cooling vapours.
5426. Sawrey & Collet ..... Separating liquids from solid matters in suspension.
5428. Crowley & Harris ... Gas burners.
5432. Heys, W. E. ..... Pulverisation of liquids (*Kron*).
5439. Ashberry, P. ..... Shears.
5445. Hill & Bryant ..... Indestructible lamp wick.
5464. Crundall, F. ..... Ships' signal lights.
5465. Pass, E. A. de ..... Water and gas cocks.
5466. Treeby, A. ..... Apparatus for carburetting air, gas, or other vapour.

COMPLETE SPECIFICATIONS ACCEPTED.

Persons interested in opposing the grant of the following patents may give notice of opposition at any time within two months after the dates given.

ENGINEERING.

14th April, 1888.

1767. Dinsmore, J. H. R..... Manufacture of gas.
5005-6. Clarke, W., & others Steam pumps.
5040. Williams, J..... Wire rope grip.
5059. Powell & Jordan..... Haulage clips.
5209. March, W..... Wrench for axle caps and nuts.
5217. Keeble & Mumford.... Machine for cutting chaff.
5225. Long, J. E..... Hand fire extinguishers.
5929. Turner, J. ..... Looms for weaving gauzes.
6501. Dawson, H. T..... Engines worked by explosive mixtures.
6981. Thompson & Spence ... Type writing machines.
7086. Haddan, P. ..... Blinds of corrugated sheet metal (*Mitter.*)
7296. Sisson, W..... Clutch mechanism.
7350. Faber, J. ..... Gas motors.
7391. Frager & Michel ..... Liquid meters.
7654. Kemp, T. T. ..... Rotary steam engine.
7677. Davy, C. ..... Gas engine.
7715. Allen & Rathbone ... Wheels and pulleys.
7731. Blackburn & Lampen.. Clip pulleys.
7911. Brierley, W. ..... Automatic dyeing coppers (*Perzina*).
7986. Bailey, M..... Safety indicator for apparatus working under pressure.
8023. Corbett, T. ..... Ploughs.
8097. Tolhurst & Skinner... Slide valve.
8111. Laing, W. R. ..... Frames for spinning, doubling, twisting, or roving fibrous substances.
8134. Dowd, G. S. ..... Bearding, scouring, and polishing grain.
8169. Lankester, P..... Apparatus to facilitate seed sowing on the broad cast system.
8182. Johnson, J. Y..... Apparatus for propelling by reaction.
8207. Burrows, H..... Open hearth steel furnaces.
8224. Harman, H. J..... Attaching railway chairs to sleepers.
8285. Neilson, W., & others... Reversing valves for regenerative furnaces.
8304. Hughes, G. ..... Lifeboats.
8325. Sykes & Sykes..... Stop motion applicable to machinery for twisting and doubling yarns.
8328. Morgan, J. H..... Grabs for dredging and excavating.
8330. Blamires, T. H..... Manufacturing yarns.
8395. Cochrane, W. M..... Breaks for road vehicles.
8408. Shelton, J..... Elastic tyred wheels.
8413. Stechmann, G. H..... Automatic feeding apparatus and feed water heater.
8414. Yeadon & Middleton.. Machinery for desiccating substances of a granular character.
8422. De Hemptinne & De Hemptinne ..... Removing oil from the cards of carding machines.
8447. Westmacott, P. G. B.... Shipping coal
8451. Turton, G..... Coupling buffers for railway vehicles.
8485. Marinoni & Michaud... Printing machines.
8525. Smith, J. H. ..... Apparatus for drying woven fabrics, yarns, or fibrous materials.
8654. Bain, W. P. C. ..... Standards for wire fencing.
8671. Yeadon & Middleton.. Disintegrators.
8698. Cowper, E. A. ..... Hot blast valves.
8838. Binns, A..... Regulating the "drag" on the fibre under operation on finishing and roving boxes.
9136. Taylor, W. ..... Self acting mules.
9619. Reid, J. ..... Stopping the leaks in the tubes of tubular boilers without obstructing the draught.
9699. Scott, W. G..... Travelling hoisting gear.
9721. Thompson, W. P..... Wind motor and apparatus for propelling vessels (*Von Schlieben*).
11078. Shelley, T. R..... Securing sheets of zinc to roofs.
11125. Mudgemarchant and Brushett ..... Tubular steam boilers.
11337. Snyers, R..... New method of mechanical connection applied to brakes and clutches.
11458. Lake, H. H. ..... Winding cops (*Palmer*).
12960. Féraud, A. L. ..... Improvements in mounting the bodies of railway carriages. (Received 24th September, 1887. Ante-dated 14th June, 1887, under International Convention.)
14344. Horsfield & Porter... Hydraulic press for mining coal.
15652. Dickinson, M. F..... Printing machine.
15783. Nichols, J..... Machinery for making wire nails.
16280. Everitt, W. E..... Manufacture of brass, copper, and other metallic tubes.
16589. Eadie, J..... Carding machines.
72. Thompson, W. P..... Type writers (*Brown*).
384. Inman, H. ..... Paper box machines.
951. Richards, W. H..... Apparatus for cooling liquids.
1468. Barham, G. ..... Measuring and weighing fluids.
1670. Sinnette, F. J..... Anchor.
1830. Imray, O. ..... Embroidering machines (*Smith*).
1841. Lieb, C. A..... Automatic grain scales.
2252. Imray, O..... Duplex rotary pumps (*Dow*).
2561. Tilton, H. W. ..... Sewing machinery (*Angell*).
2608. Köhler, J..... Sewing knitted fabrics.
2922. Johnson, J. Y..... Sewing knitted fabrics (*Quinquarlet, Valton, & fils*).
3173. Grassnick, F. ..... Machine for drilling holes for planting potatoes.
3449. Justice, P. M. ..... Railway switches (*Isbell*).
3531. Taylor, W. H., & others Loom temples.
3542. Watson, C. T. ..... Machines for printing cards.
3587. Burtscheidt, G..... Weaving pile fabrics.
3656. Lund, E. ..... Pulsometers.
3718. Klauke, C. ..... Barbed wire for fencing purposes.
3789. Baker, G. W. ..... Leather staking machine.
3801. Selwig, J..... Rotary engine.
3816. Hainsworth, F. ..... Wire fabric for mattresses.
3819. Thompson, W. P..... Spark arresters (*Jessl*).
3837. Sleeper, F. H..... Lifting jacks.
3854. Ward, J. F. ..... Vessels' rams.
3918. Hamilton, H. ..... Apparatus for composing type (*The Thorne Machine Co.*)

ELECTRICITY.

14th April, 1888.

6221. Shippey & Hamilton... Governing motors by electro-chemical action.
6581. Manville & Madgen... Holders for electric lamps.
6744. Walkington, W..... Fire box and boiler.
9853. Watt, H. ..... Dynamo-electric machines.
12017. Verchère, P. L. ..... Carbons for voltaic batteries.
16709. Edison, T. A..... Electrical generators. (Received 5th December, 1887. Antedated 13th June, 1887, under International Convention.)
633. Coerper, C. ..... Dynamo-electric machines.
734. Noad, J..... Galvanic batteries.
3483. Schmidt, F. T. ..... Electrical switches.
3685. Sharp, S., & others..... Electrical switches.
3740. Bernstein, A. ..... Cut-out and switch.

CHEMISTRY.

14th April, 1888.

7761. Jones & Jones..... Oxides of iron.
7859. Staub, L. A..... Carbonate of soda.
7906. Schneider, R. ..... Hydrate of baryta.
8129. Staub, L. A..... Carbonates of soda.
8265. Pitt, S. ..... Naphthol disulphonic acid and dyestuffs therefrom (*Leopold Cassela & Co.*)
8387. Traube & Bodländer.. Separation of fusel oil.
1693. Nicolle, A. ..... Manufacture of phosphorus.

MISCELLANEOUS.

14th April, 1888.

5001. Whitehead, J..... Automatically tightening nuts for the adjustment of bearings to compensate for wear.
5270. Rappaport, L. ..... Utilising the waste of flour mills.
5470. Kendall, P. F..... Determination of the dip of rocks in deep bore holes.
6966. Phillips & Harrison... Reflectors of light.
6995. Catling, R. C. ..... Washing barley before malting.
7331. Ross, J. H..... Oil lamps.
7560. Ashley, H. M. ..... Internally stoppered bottles.
7952. Drake-Brockman, R. R. E..... Attaching ropes or cables to each other.
7996. Ross & Bilbie ..... Manufacture of boots.
8086. Lorrain, J. G..... Cable sleeves.
8174. Dutton, S. T. ..... Railway signal lamps.
8231. Alexander, W. ..... Sheaves for pulley blocks.
8319. Attock, F. ..... Draught and dust excluder.
8456. Beesley, J. ..... Velocipedes.
8501. Holland, H. W. ..... Telescopic sights for rifles.
8514. Leak, E. ..... Glass spinning rings.
8591. Wood, R. ..... Straining paper pulp.
8782. Wood & Wood..... Straining paper pulp.
9211. Crompton, R. ..... Colouring and drying tissue paper.
11452. Horton, E. ..... Oil lamps.
11654. Musgrave, S. H..... Bottle stoppering.
14364. Greenwood, J..... Valves.
4. Räuerle, T. ..... Lamp clocks.
1026. Beer, A..... Frictionless gate spring.
1794. Watkin, H. S. S..... Instruments for measuring distances.
1870. Shepherd & Shepherd Oil lamps.
2656. Thompson, W. P..... Dust and shavings collectors (*The Knickerbocker Co.*).
2774. Lake, H. H. ..... Manufacture of boots (*Ross*).
3172. Jones & Bridger..... Manufacture of boots.
3318. Bayer & Lease. ..... Tricycles.
3320. Surprenant, L..... Nut lock.
3716. Ibbotson, E. C. ..... Lock nuts.

PATENTS VOID THROUGH NON-PAYMENT OF RENEWAL FEES.

(To the 7th January, 1888, inclusive).

Year 1884.

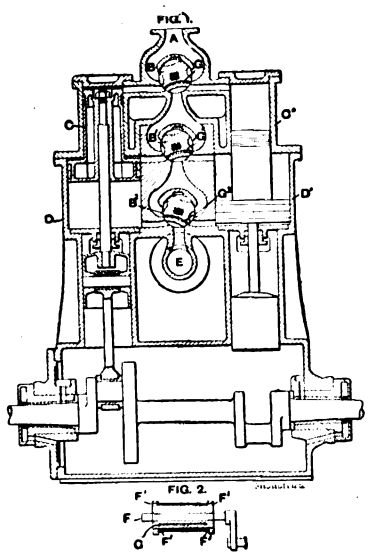
ABSTRACTS OF BRITISH PATENT SPECIFICATIONS.

Compiled from the Published Specifications by W. E. Heys, 70, *Market-street, Manchester.*



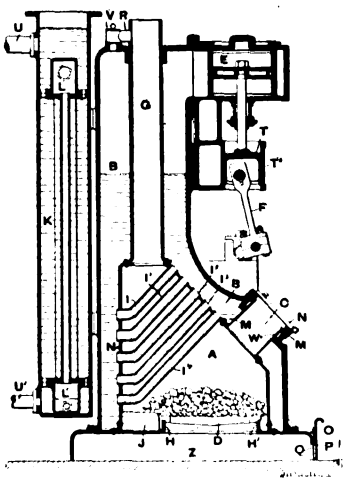
ENGINEERING.

Breech Mechanism for Ordnance.—*T. Nordenfelt, London.*—In the guns to which this invention is applicable, the breech is closed by a block entering the breech opening, and screw threads on the block engage with threads within the breech of the gun. In the improved mechanism the necessary movements are given to the block by a lever handle and axis, which revolves through the arc of a circle, and the extractor is also actuated by the same means. A flanged ring is fixed on the breech end of the gun, and upon it are bearings for a vertical axis, which carries the lever handle. This axis is on one side of and a short distance in the rear of the breech opening. An arm at the upper end of the axis carries a stud to engage with a notch in a sliding bar, which is carried in guides and moves transversely to the bore of the gun. The same bar has another notch in it, which engages with a stud upon the breech block. During the first part of its movement in opening the breech, the bar slides in its guides, and turns the breech block through an angle of 60°, and disengages the screw threads upon it from those within the gun; the stud on the lever handle then escapes from its notch in the transverse horizontal bar, and travels on while the bar remains at rest. A collar on the rear end of the breech block turns freely, and carries a stud which projects downwards through two different slots. One of the slots is cut longitudinally in a support which receives the breech block when it is withdrawn, and the other slot is formed in an arm by which the withdrawal of the breech block from the gun and its replacement after loading are effected. This withdrawing arm and the support or tray are mounted loosely on the axis of the lever handle; both of the parts remain stationary during that portion of the movement already described. In opening the breech a shoulder on the lever handle comes against a similar projection upon the withdrawing arm, and the latter commences to turn, while the lever handle moves rearwards from the breech. The breech block is drawn out and landed upon the tray, which then turns round with the lever handle. In closing the breech the same movements take place in the reverse order. In order to insure this sequence of movements, a bolt is provided on the withdrawing arm, and a piece fastened to the axis of the lever handle gives motion to it. A stud upon the piece enters an inclined groove in the bolt while the unlocking movement is in progress. The extractor slides in a horizontal groove

Digitized by Google

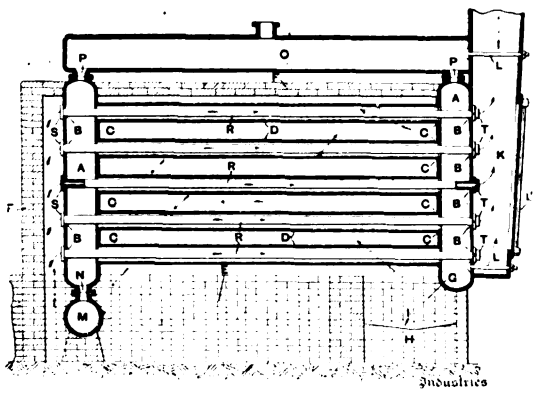
on one side of the breech opening. It has a lip which overlaps the flange at the base of the cartridge, and has a screw thread formed upon it at the side. When the breech block is turned to open the breech, the thread upon the block engages with the thread upon the extractor, which is consequently withdrawn, and the cartridge case is loosened in the bore. When the block is drawn rearwards, the extractor is also drawn back, carrying the cartridge with it. When the breech block has been landed upon the tray, its screw thread leaves that on the extractor, which afterwards remains at rest at the rear end of its guide groove, and is locked by a sliding bolt. The face of the breech block is inclined at the sides, and, in loading, this cavity effects the centreing of the cartridge and insures it entering the gun truly. Seven claims are made.—No. 7195. May 17th, 1887. 11*d*.

Slide Valve.—*A. G. Brown, Cathcart, North Britain.*—The valve here described is adapted for use in multiple cylinder single acting engines, and is substantially of cylindrical outline, but is cut away at certain points, so that the section resembles a Maltese cross. The motion of the valve is reciprocating, and its travel extends through less than one quarter of a revolution. The method of working will be understood by reference to Fig. 1, which represents a section of the valves when employed in a four cylinder engine. Fig. 2 shows detached a longitudinal view of one of the valves. Steam is admitted into the steam chest A on both sides of the valve B. The steam passes through a recess on one side of the valve to the port of the cylinder C, and also through the auxiliary groove G. While steam is being thus admitted, the exhaust from the second cylinder C^1 is open, and the discharge takes place through the recess between the bearing surface of valves $B B^1$ to the top of the cylinder D. The exhaust from beneath the cylinder D is open through the recess in B^2 to the final exhaust E, while the exhaust from the top of the



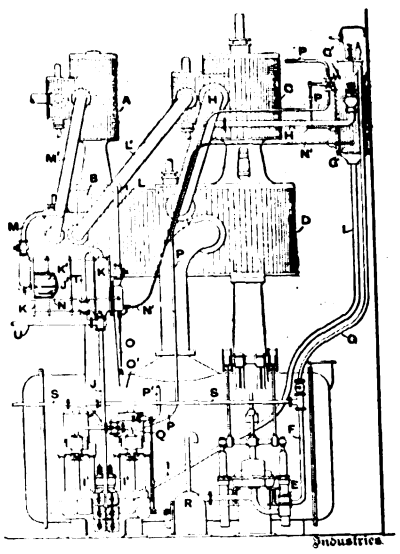
piston in the cylinder D^1 is open through the valves $B^1 B^2$ to the bottom of the same cylinder. It will thus be seen that while pressure is being exerted upon the top of the pistons in the cylinders, the final exhaust, if connected with a condenser, is pulling in the same direction from beneath the lower pressure piston. When the valve motion is reversed, the steam inlet to the cylinder C is closed, and just before the inlet to the cylinder C^1 is opened, the supplemental passage G opens communication momentarily between the two cylinders C and C^1; the expanded steam from the first cylinder thus exhausts partially into the second cylinder, just before the full steam pressure is admitted. The further movement of the valve B closes communication between the cylinders $C C^1$, and opens the latter to full steam pressure; the former completes its exhaust through the valve B^1 to the top of the cylinder D^1, and the final exhaust from beneath the piston in the cylinder D^1 is at the same moment opened through B^2 to E, while the exhaust from the top to the bottom of the cylinder D is opened through the valves $B^1 B^2$. The passages $G^1 G^2$ open communication momentarily between the cylinders $D D^1$ in the same manner as the passage G. The stems F are journalled at each end and are carried in bearings, with the object of holding the valve centrally in its seat and of decreasing the wear. Any ordinary means may be employed for operating the valves; and for the purpose of balancing with regard to exhaust, communication is made between the bottom and top recesses of the valve. This may be done conveniently by the passages F^1 shown in Fig. 2. Three claims are made for the form of the valve, and for the supplemental passage.—No. 5134. April 6th, 1887. 8*d*.

Excavators.—*J. Garvie, London.*—This invention relates to the combination of an ordinary traction engine or portable engine with an excavator. Any known form of excavator worked on slides, or by an arm or jib, is to be driven by a portable engine by means of belt or other gearing. The excavator is preferably in a separate frame, so as to be easily attached to and detached from the engine, and is arranged in such a position as to obtain the full advantage of the engine for the purpose of a counterbalance. One claim is made for this combination.—No. 7081. May 14th, 1887. 4*d*.



Flax Spinning Machinery.—*L. MacLaine, Killyleagh, Down.*—The object of this invention is to improve the quality of the rollers used in flax spinning frames, in which it is desirable that the surfaces of the bosses on the drawing rollers shall be equally dense all round, and free from cracks and flaws. The roller shafts are to be constructed of iron, steel, or other material, and the fluted bosses are cast on intermediate cylinders. The fluted bosses are placed either at the centre or at one end, or in any other position on the intermediate cylinders. The bosses and intermediate cylinders are cast under pressure, and then bored out and shrunk on the roller shaft; they are then turned up and fluted. The inventor claims the construction of the roller shafts of flax spinning frames, with bosses and intermediate cylinders fitted on separately.—No. 7845. May 31st, 1887. 6*d*.

Steam Boilers.—*H. Davey, London.*—These boilers are intended for the generation of steam for low pressure motors, and are specially designed for the purpose of insuring safety against explosion, although requiring comparatively little attention. The boiler shown in vertical section in the accompanying figure embodies several improvements in the boiler which forms the subject of Patents Nos. 3833 and 15185 of 1884. The boiler B and fire box A are secured to the bed plate Z. The bed plate has two projections $H H^1$ for the support of the fire bars D, and is



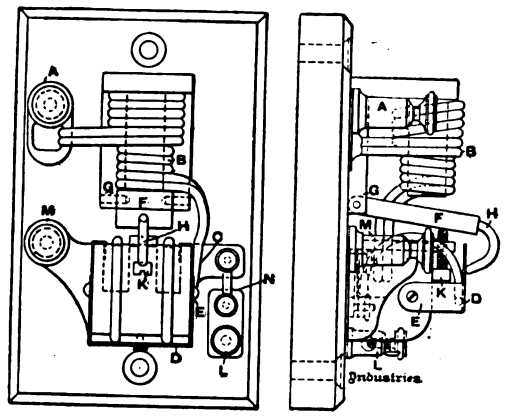
provided with a damper door O, which slides on a plate P in front of the opening Q. By adjusting the position of the damper door in front of the opening the supply of air may be reduced to any degree. The fire box A is provided with additional heating surface by the tubes I, which are placed at an angle, so that the water in them will rise and produce a general circulation in the boiler. The mouth piece C is fastened to the fire box A, and serves for the introduction of fuel; its junction with the boiler is made by means of the packing in the recess L, which is kept tight by the ring M. The block of fire brick J prevents the coal from lodging behind the projection H. The cylinder E and the cylindrical guide T^1 are made in one piece, and are fastened to the boiler; the cylinder is so arranged that the steam is allowed a free passage around it. The distribution of steam in the cylinder, its subsequent exhaustion into the condenser K, and the extraction of the condensed water from the latter, are described in the previously mentioned specifications. The blow-off valve box V contains an ordinary single beat valve, and is provided with a pipe R for conducting the surplus steam into the flue G. Two claims are made for the construction of this boiler as described, and for another modification.—No. 1160. January 25th, 1888. 6*d*.

Steam Boilers.—*O. H. Gentry, Opelousas, Louisiana, U.S.A.*—The accompanying figure represents a longitudinal central section of a steam boiler embodying the present improvements. A pair of circular drums A are provided with openings B in their outer sides, and with larger openings C on their inner sides. The series of horizontal water tubes D have their ends connected to the openings C, and extend from one drum to the other. The

drums are supported upon a setting of brick work E, and are retained in their vertical position by the connecting pipes D. The casing of brick work F surrounds the boiler completely, and in one end of it a combustion chamber G is built. The smoke stack K is secured to the drum A and steam drum O by means of the bolts L, and communicates with the openings B in the front drum. The door L^1 enables the attendant to clean out the smoke stack periodically. M represents a mud drum which is arranged transversely under the lower side of the rear drum A. The outer sides of the drums A are connected by means of the horizontal flues R; one end of each of these flues is swaged and provided with an annular flange S, which extends laterally, and bears upon the outer side of the rear drum A. The opposite ends of the flues are screw threaded, and extend through the outer side of the front drum A; non-corrosive nuts T are screwed on these extremities, and bear against the outer side of the rear drum, and so secure the flues. The outer sides of the nuts are bent over inwardly, so as to form lips that cover the ends of the flues and protect them from direct contact with the fire. The inner edges of the lips are made flush with the inner sides of the pipes R, in order to prevent the lips from obstructing the passage of the products of combustion through the flues. When the boiler is filled, the water in the drum A and tubes D entirely surrounds the flues R. When a fire is lighted in the furnace the smoke and hot gases pass upward round the water tubes, and circulate round them in the direction indicated by the arrows until they reach the rear drum A. The current is then deflected, and passes under the rear drum and through the flues R into the stack K. It is claimed that by providing the drums with the water tubes D and tubes R, the boiler is given a maximum amount of heating surface, and that, consequently, the steam is generated with the smallest possible consumption of fuel. Two claims are made: (1) For the combination of the drums A, water tubes D, and flues R, with the mud drum M, steam drum O, and smoke stack K; and (2) for the combination with the tubes R of the nuts T screwed over one end of the flues, the outer sides of the nuts being bent inwardly to form lips that covers the ends of the flues, as described.—No. 1329. January 28th, 1888. 6*d*.

Feed Water Heater.—*J. Weir & G. Weir, Glasgow.*—The object of this invention is to economise fuel by heating the feed water by steam which has operated to a certain extent in the engines, but which is applied for that purpose before its final exhaust. The accompanying figure illustrates the application of this invention to a quadruple expansion screw propeller engine. The feed water is first pumped by the engine E, and is delivered at a moderate pressure through the pipes F G into a feed heater G^1, in which the water is brought into immediate contact with the steam. The steam for this purpose is supplied through a pipe H, which is connected to the exhaust pipe H^1 of the third cylinder C. The partly heated feed water passes from G through a pipe I to a set of donkey pumps I^1, which supply the requisite pressure to the water to enable it to enter the boiler. The pipe J conducts the water to one compartment J^1 of a feed heater casing K, which is composed of the two compartments J^1 K^1. These compartments are surface feed heaters, and the steam which heats the water acts inside a tubular apparatus. The steam in the lower compartment is supplied by a pipe L, connected with the exhaust pipe L^1 of the

second stage cylinder B; the steam in the upper compartment is supplied by a pipe M, connected with the exhaust pipe M^1 of the high pressure cylinder A. The water of condensation in the tubes of the high temperature surface heater K^1 is led by a pipe N into the steam inlet compartment of the next lower temperature feed heater J^1. The water will here impart its heat to the feed water, which is at a lower temperature than the water of condensation. In a similar way the water proceeding from the heater J^1 is led by the pipe N^1 into the lowest temperature feed heater G^1. If found preferable the water may be led by a pipe O directly to the main condenser O^1. Several automatic regulating devices are used in different parts of the engine. The steam to work the donkey pumps I^1 is supplied by a pipe P, which has a regulating valve controlled by a float within the feed heater G^1; or the steam to I^1 may be supplied by the pipe P^1, which is provided with a regulating valve Q, worked by a float in the hot well R. The feed water may be pumped from the main engine pumps E directly to the boilers through the pipe S connected to the delivery pipes of these pumps. When the feed water passes through all the heating apparatus, it proceeds to the boiler from the compartment K^1 through the pipes T U. The latter pipe is also connected to the donkey pump delivery pipe J. The inventors make three claims for the arrangements for heating the feed water for the boilers at successive stages with portions of steam which have worked to different extents, the feed water being pumped to its highest pressure before passing through the highest heating stages.—No. 6190. April 28th, 1887. 8*d*.



Rolling Chambers for Ships.—*G. P. Thomson & J. H. Biles, Glasgow.*—The inventors introduce two improvements into the construction of the water chambers used for the purpose of reducing the rolling of ships. The chamber is to be made narrower at its middle line than near the sides of the ship, by one or both of the transverse sides being made concave in plan. The other modification of previous forms is the provision of movable partition plates for varying the extent of the contraction of the rolling chamber at the middle line. The period of flow of the water from side to side can in this way be varied according to the period of roll of the ship, and the shock of the water against the sides is considerably diminished. Two claims are made: (1) For the contraction of the chambers at their middle lines, and (2) for the movable partitions for varying the contraction.—No. 1296. January 28th, 1888. 6*d*.

ELECTRICITY.

ELECTROMOTORS.—*J. D. F. Andrews, Glasgow.*—The construction of electromotors devised by the present inventor makes the action of the machine independent of the alternations of the current. The inventor employs any known form of dynamo which may have several polar fields; the cores of the magnets are of iron wire or thin iron plate. The coils of the armature and commutator plates are arranged and connected to the field magnet coils in such a manner that, whether the supply current be in one direction or the other, each armature coil has for the moment a polarity opposite to that of the field pole towards which it is presented; the reversals of the current act similarly and synchronously on both the armature and field magnet coils. Whatever may be the period of the reversals of current produced by the generating machine, the movement of the motor is independent of them in respect of time. In a modified arrangement the field magnets are made without iron, and the coils are arranged so as to envelop the armature and act on it direct. The armature may also be made without a core of iron. Two claims are made: (1) In an electromotor adapted to be worked by alternating currents, connecting the commutator brushes through the field magnet coils to the leads from and to the generator, so that alternations of current produce synchronous alternations of polarity of the field magnets and of the armature coils; and (2) for dispensing with the cores of the field magnets, as above described in the modification.—No. 6621. May 5th, 1887. 8*d*.

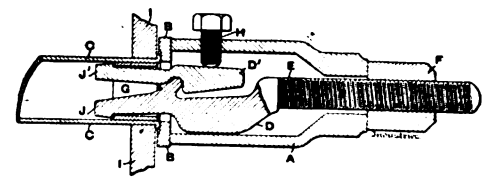
MAGNETO-ELECTRIC CUT-OUT.—*W. H. Scott & E. A. Paris, Norwich.*—The construction of this cut-out is shown in the two accompanying figures. Fig. 1 represents a front elevation with the circuit broken, and Fig. 2 a side elevation with the circuit complete. The current is led from a contact A, round the core B, to the contact C, through a mercury cup across the pivoted bridge piece D, into a second cup, and thence through the circuit. The bridge between the mercury cups is pivoted at E, and an armature F, which is pivoted at G, is provided with a detent H, in order to hold the bridge in position and to keep the circuit complete. On any increase of current through the coil of the

electromagnet, the armature is attracted and the detent releases the bridge piece; in its fall the contact fingers are withdrawn from the cups, and the circuit is broken. The distance of the armature from the pole piece is made adjustable by means of the screw K. A small extra terminal L may be connected to the main conductor. In incandescent lamp circuits a lead from one or more lamps might be connected to this terminal, and the other lead connected to the terminal M. The lamp would be short circuited when the main circuit was complete; but when the main circuit was broken the lamp would be in circuit, and the current would pass through it instead of through the bridge and cups, and would indicate, by the comparative brightness of the lamp, the nature of the cause which had brought the cut-out into action. By means of the extra terminal any resistance might be brought into action automatically; and a small safety fuse N might be inserted between the cut-out conductor and the small extra terminal. The inventors claim: (1) The combination of an electromagnet with a pivoted adjustable armature normally holding a bridge piece completing the circuit, but which, on excess current causing the armature to be attracted, allows the bridge to drop and the current to be broken; (2) the combination of such a device with an auxiliary circuit containing the lamp; (3) the combination of this device with the safety fuse.—No. 6590. May 5th, 1887. 6*d*.

SECONDARY BATTERIES.—*R. E. B. Crompton, Chelmsford, and J. C. Howell, Llanelly.*—Certain improvements are introduced by this invention into the arrangement of the lead plates employed in electrical accumulators. The separators which keep the lead plates apart are strong cylindrical rods of insulating material, which will withstand the attacks of sulphuric acid. At the bottom of the cells are placed frame works or grids, which are made of lead; the lower ends of the separator rods enter grooves in the grids, so that the rods are maintained in a vertical position at the proper distance apart even when the plates are removed. When this grid is made of lead it may be used as the piece on which the spongy or grey plates are electrically connected. These plates are sometimes attached in such a manner that they stand on the lead grid, and are burned on to them. The peroxide or brown plates are supported by one or more stout cross bars resting on the edges of the cell. In another form of supporting rods the inventors make the grid of insulating material; in this case both the grey and the brown plates rest on the ribs of the grid. In another form the grid is dispensed with altogether, and the plates rest on insulating ribs at the bottom of the cell. The supporting rods may also be made U shaped. These separators are supported in the cells by being placed so as to hang astride of bars above the upper surface of the plates. This form has the advantage of being laterally elastic, and by suitable hanging pieces it can be made to expand with the plates. The most suitable materials for the rods are xylonite, vulcanite, glass, and vitrified porcelain. Another form of separator employed by the inventors is of a corrugated form, and pierced with a number of holes. The present invention also includes several methods of attaching the wires to the plates. These connecting wires are to be made of lead, and are burnt into the plate. A wire is burnt to the side of the plate at two points near together, and sometimes a second wire is burnt to the top of the plate at two points also close together. One or both of these wires are carried from each plate to a connecting bar, in which taper holes have been punched for the purpose of receiving these wires. The holes are punched in such a manner as to raise a burr on the upper surface of the bar. The wires, after being inserted, are lightly riveted over, and the soldering flame is passed over the burr; a sound metallic connection is thus made, which, however, can be easily disconnected for purposes of repair by removing the burr with a chisel. The connection from cell to cell is made by an upright cylindrical insulated pillar of lead. Eight claims are made.—No. 6681. May 6th, 1887. 8*d*.

DYNAMOS.—*R. E. B. Crompton & W. A. Kyle, Chelmsford.*—This invention relates to an improved method of coupling the bars or wires which form the conducting circuit of drum armatures. The difficulty experienced in coupling the bars across the ends of the drum has been that the bars and connections first put on to the core cannot be removed for repair without necessitating the removal of the superincumbent portions. In overcoming this defect the inventors connect the ends of each pair of bars by means of a peculiarly shaped connecting piece or coupler. This coupler is formed of copper or other similar material, and consists of a flat strip cut so as to be cranked in one plane and curved in the other plane; the cranking and curvature is such that the desired number of bars can be coupled, and the longitudinal space occupied is not greater than the width of one coupler. The couplers are sometimes divided at a convenient point, so that they can be withdrawn in two pieces, and the two halves are connected to the bars by a screw or other connection. When in position the couplers are arranged in a ring, whose inner edge has a slightly greater radius than the outer edge of the circle of bars. The ends of the couplers can thus be attached to the outer edge of the bars, and when any one bar is released it can be drawn out longitudinally. The field magnets of the dynamo are made of the single limb type. The machine is arranged vertically with the armature below; the limbs of the magnets are made of wrought iron, and the pole pieces for the lower side of the armature are made of cast iron, or of separate blocks of wrought iron, and these are so joined to the wrought iron field magnets that the latter may be detached and removed bodily to allow the armature to be inspected. Two claims are made: (1) For the pole pieces constructed with the capability of detachment from the magnets, to admit of easy access to the armature, as described; and (2) for the connectors applied to the armature externally to its circumference.—No. 6409. May 2nd, 1887. 8*d*.

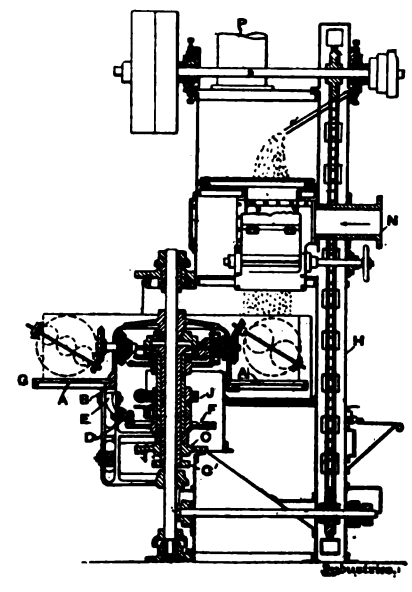
CHEMISTRY.



SEPARATION OF METALS.—*C. B. Schultze, Leipzig.*—This invention is applicable to the treatment of factory waste and to the recovery of iron from scrap tinned plate. Dilute sulphuric or hydrochloric acid is added to the raw material. If there is any zinc or cobalt contained among the metals, the solution is allowed to filter over sheet zinc; the copper, bismuth, lead, tin, cadmium, and nickel are first separated, and afterwards iron and cobalt, in the form of insoluble basic sulphates. If there is but little zinc present the solution is treated with a neutral or acid solution of sesquioxide of iron, or with a free acid in which the hydrated peroxide or sesquioxide of iron is suspended. If the mixture contains tin, copper, bismuth, nickel, or cobalt, the oxides of these metals are formed. If iron is not present in the raw material the solution is brought into contact with iron, and the copper and bismuth are precipitated in the metallic state, while the lead is partly precipitated as a metallic powder and partly in the form of sulphate. The remaining solution is then neutralised by the addition of metallic tin and hydrated peroxide of iron, and pure metallic iron is brought into contact with the neutral solution, by which means the tin and nickel are deposited. The undissolved residue is well mixed with scraps of metallic iron, and dilute sulphuric acid is poured over it. This mixture is allowed to stand for several weeks, during which period it is several times turned over. The insoluble oxides are converted into metals and soluble oxides, and any iron which is present is converted into protoxide of iron. Metallic copper, lead, and bismuth are ultimately formed together with the sulphates of tin, iron, nickel, and cobalt. The latter substances are neutralised, and the tin and nickel recovered by the addition of metallic iron. Seven claims are made for the various modifications of this process.—No. 3669. March 10th, 1887. 6*d*.

EXTRACTION OF ZINC FROM ORES.—*A. Watt, London.*—In order to extract zinc from the ore, or from an impure mass containing zinc, the inventor uses the impure mass as the anode of an electric battery. The acid employed as the electrolyte is to be some vegetable acid, preferably acetic. On a current being passed through the solution, the zinc is deposited in a purified state on the negative electrode. In treating some of the ores of zinc—for instance, calamine or native carbonate, the zinc is first digested in the vegetable acid, and the solution thus obtained is employed as the electrolyte. In this case the anode and cathode are carbon or platinum and zinc or carbon respectively. The latter process may be employed on a large scale for the separation of zinc. Two claims are made, one for each method.—No. 6294. April 29th, 1887. 6*d*.

DRY CALCIUM HYDROXIDE.—*J. Pfeiffer, Kaiserlautern, Germany.*—This invention relates to an improved apparatus for treating caustic lime with water, whilst under considerable pressure. The process is carried on inside a large cylindrical iron retort which is built in brick work. At one end is a door, through which the workmen can introduce a long semi-cylindrical iron vessel. This vessel is supported on runners, and is filled with the caustic lime. The retort is provided with a pressure gauge and a safety valve. A definite amount of water is showered over the lime by means of a series of longitudinal perforated water pipes. The pressure rises as the lime becomes hydrated, and the steam which is given off is prevented from condensing by the retort being heated by some external means. The advantages of this apparatus are that the charge of lime is easily introduced into the cylinder; that the chance of injury to the workmen is very much reduced, and that the hydrated lime is prevented from absorbing more water than is requisite. Two claims are made.—No. 43. January 2nd, 1888. 6*d*.

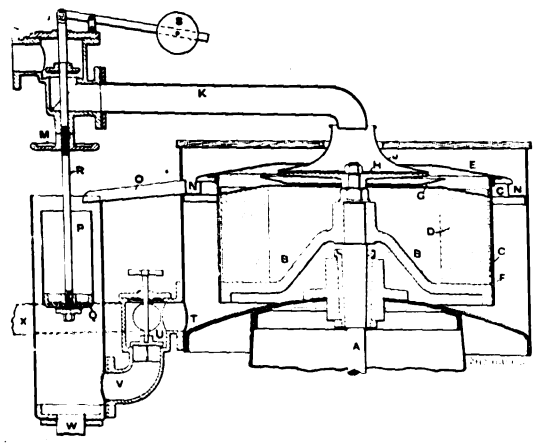


MISCELLANEOUS.

EXTRACTING FERRULES FROM BOILER TUBES.—*H. W. Swift, Ince, Lancashire.*—This invention has been designed for the purpose of extracting the ferrules out of boiler tubes without entailing any damage to the boiler. In the accompanying figure A represents a stout cylindrical box, with its open face abutting on a ring B placed against the tube C. The box has two jaws D D¹ inside it; one of these jaws D terminates in a screw E, which passes through a hole in the end of the box A, and is provided with a nut beyond. This jaw is so shaped as to be supported against the contiguous side of the box, and its end has a projection J to overlap and hold to the ferrule G. On the opposite side the jaw D is provided with a projection fitting a hollow in the other jaw D¹. It might, instead, have a hollow fitting in a projection on the jaw D¹, or might be hinged to the top jaw in an equivalent manner, so as to form a fulcrum for the top jaw, and be able to drag the top jaw with it when screwed up. The jaw D¹ has also a projection J¹, which catches the ferrule G. Through the side of the box A is fixed a set screw H, which, by pressing the tail of the jaw D¹ beyond its

fulcrum on the other one, keeps the jaws distended. I is the boiler plate, to which the tube C is fixed. In operating this apparatus the box A is placed against a ring B, which is cut to the right size, and the claws are inserted beyond the ferrule; the screw H is then tightened until the claws fit over the ferrule. The main screw E is now screwed up until the ferrule is drawn out of the tube. Instead of two jaws a single stem projecting into the tube may be employed, which has two hinged wings pointing obliquely outwards, or hinged grippers pointing inwards, and kept apart by a spring. It is also possible to substitute a spring for the set screw H, but the method illustrated in the figure is preferable. The inventor makes two claims for the extractor having the two expanding jaws D D¹ provided with claws J J¹, and for the combination of the set screw, main screw, and washer, with the jaws, for the purpose described.—No. 6078. April 26th, 1887. 8*d*.

SAND BLAST.—*G. R. A. Gutmann, Ottensen, Germany.*—The objects of this invention are to obtain a regular distribution of air over the whole length of the air nozzle, and to facilitate the transport of the pieces to be treated by the current of sand. The pieces are arranged on an intermittently rotating annular table; inside the air nozzle are two or more partitions, which distribute the air over the whole length of the nozzle slot. The air nozzle is surrounded by the sand nozzle, and suitable dampers regulate the admission of air. An application of this method is illustrated in the accompanying figure. The rotating table G is fixed to a vertical shaft, which carries a cylindrical casing and



a bell-shaped casting; the latter serves to support the mechanism for holding and revolving the pieces to be sanded. The revolving mechanism consists of a shaft and bevel gear, a loose socket and its outside extension, a spring, and other bevel gear. The table is periodically turned so as to bring one of the objects under the sand blast for a certain interval of time; this movement is effected by a click which actuates the ratchet wheel B. A sleeve is connected with the stationary frame, and forms a bearing for an intermittently rotating shaft. A cam on the upper end of the sleeve acts upon the horizontal shafts in such a manner as to disengage the holding mechanism at the place of the operator, and to allow the replacement of a new piece. The two discs C C¹ bring the sleeve out of gear, and the sleeve also serves to guide a hollow shaft which carries two bevel wheels gearing with those on the horizontal shafts. The worm wheel J and the disc F have an annular course formed in them for the roller D, and the worm wheel J is driven continuously

Digitized by Google

by a worm which has motion imparted to it by the main shaft. The motion of the pieces to be sanded corresponds to the form of the object and the character of the design. Five claims are made.—No. 4217. March 21st, 1887. 11*d.*

CENTRIFUGAL FILTERS.—*W. Jäger, Könkendorf près Pritzwalk, Germany.*—The chief difficulty which is met with in getting an ordinary centrifugal machine filter to work is that the charcoal will not rise and form a solid wall against the rotating cylindrical surface of the casing when the water is mixed with it. The machine here described and illustrated is designed specially for the purpose of overcoming this fault. The rotating drum is mounted on the vertical shaft A, and its cylindrical surface C is composed of perforated metal lined with metal gauze F. The filtering material D is shown in the position it assumes when the machine is rotated. After the charcoal and water have been placed in the interior and the drum set in motion, a jet of water from a rubber hose is made to play on the charcoal until the latter has reached the top of the drum. The vertical wall of charcoal is thus formed, and the difficulty before mentioned is

overcome. The ordinary distributor is then fastened to the shaft A; it consists of the flat, round, fluted plate H and the bell J. The upper space above the charcoal serves to break the shock of fluid coming from the distributor. From this space the fluid runs along the lower edge of the ring G, and passes over the upper edge of the plate on the top of the charcoal, and into the filtering space B. By means of the centrifugal power the fluid escapes through the charcoal D, gauze F, and perforated shell C, and runs off through the hole T. The fluid is not clear at first during the time that the machine is being prepared, so the valve U is lifted to allow of its being conducted through the outlets T U V W to waste. After a short time the valve U is closed, and the filtered fluid runs off through the pipe X. In order to keep the fluid always at the same level above the inlet surface of the filter, the influx of the fluid is regulated automatically. The valve L in the inlet pipe K can be adjusted by the hand wheel M, and is connected by means of the rod R to the bell P. The bell catches the fluid that runs over the edge E through the gutter N and spout O, and lets it escape through the adjustable valve Q. When the outflow increases the bell P sinks together with the valve L, and consequently decreases the influx of the fluid. The weight S counterbalances the rod R and bell P. Five claims are made for the method of establishing the vertical wall of filtering material, for the means of destroying the first shock of the water, and for the regulating apparatus.—No. 2599. February 19th, 1887. 8*d.*

SAFETY PLUGS FOR BOILER TUBES.—*E. H. Parry, Swansea.*—The object of this invention is to protect the fusible metal of the plug from the chemical action of the water in the boiler, and the gases in the furnace. The body of the plug consists of a short brass tube turned and finished all over, and screwed at the lower end into a hole tapped in the furnace tube crown. At the upper part the body is formed with a valve seating for the support of the cap, which consists of an inner conical plug and an outer conical ring of brass. The outer ring or shell is formed at its narrower end with a circular rim projecting inwardly; the internal diameter of the opening inside the rim is slightly smaller than the outside diameter of the conical plug at its smaller end; and the rim overlaps this end of the plug. Both parts are turned and fitted together by grinding, so that the rim forms a flat or conical water tight valve seating for the plug. Circular grooves are cut on the outer surface of the plug and on the inner surface of the ring. The two parts are held together upon each other at the water tight seating, while the molten white metal alloy is poured into the annular space between them. The metal, on cooling, holds the two parts together. The larger end of the cap thus formed is turned and ground to fit the valve seating on the top of the body of the plug, and is held in position by a cotter which is passed over the top of the cap and through lugs cast upon the seating tube. The inside diameter of the valve seating is $\frac{1}{16}$in. to $\frac{1}{8}$in. larger than the greatest exterior diameter of the conical plug; the cap thus rests upon the seating partly with its outer ring and partly with the fusible alloy, and the inner plug can drop through the valve seating when the alloy becomes fused. The fusible metal is thus protected from the water by the water tight lip of the ring, and from the action of the gases by the seating. Three claims are made for forming the outer shell of the cup with an internal flange, and for arranging the cup so that the fusible alloy rests on the seating of the cup.—No. 6713. May 7th, 1887. 8*d.*

ANCHORS.—*W. C. Johnson & S. E. Phillips, London.*—The ordinary mushroom anchors have the disadvantage of becoming useless in the case of breakage. The present inventors make the cast iron head and shank in two separate parts; the mushroom head is cast with a central boss, having a hole through it for the passage of the shank. The shank is preferably of a square section, and after being placed in its position through the hole in the head a shackle is fixed to it by a screwed pin passing through a traverse hole. The mushroom may either be left loose on the shank or it may be retained in position by a pin or set screw. By this construction of the anchor a great saving is made in the stowage space on board ship, as the parts can be kept separate until required for use. The inventors claim the construction of mushroom anchors with the cast iron head and the shank in two separate parts.—No. 7675. May 26th, 1887. 6*d.*

BOLTS AND RIVETS.—*T. Woodhead, Bradford.*—In order to strengthen the bolt or rivet the inventor forms a curved or rounded recess in the head at its junction with the body of the rivet or bolt. The advantage of this form is that the fibre of the metal is not weakened by a sharp joining edge, while it necessitates no special shape for the holes which they are adapted to work in. One claim is made for this form of bolt and rivet.—No. 770. January 18th, 1888. 6*d.*

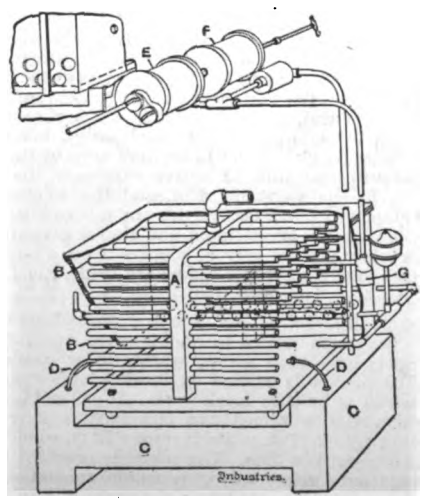
KNITTING MACHINES.—*L. A. Groth, London.*—Arrangements are made in this invention by which hose material of any width may be made on the Lamb machine, without the use of stoppers for regulating the cam when the lever is pulled. In order to work the back and front needles alternately, the middle lifter portions of the corresponding cams must be alternately thrown out of action. The triangular cam has one of the lower angles detached, and is kept in its lowest position by means of a spring. The work will be carried on as usual in one direction; but on reversal the needles will stop against the surface of the cam where the corner has been taken off. The cam will be raised by the push of the needle into a sufficiently high position for it to slide over the feet of the needles. On the last needle passing, the cam is restored to its normal position by means of the spring. The middle part of the cam will thus act upon the feet of the needles while working in one direction; but whilst working in the contrary direction the needles will remain at rest. One claim is made for this method of automatically operating the cams.—No. 846. January 19th, 1888. 6*d.*

FILTERING SPENT OILS.—*T. Turner, Preston.*—The apparatus designed by the inventor for the purpose of filtering oil consists of a cistern which has a slanting bottom, and a coiled pipe underneath the vessel for heating the oil. The vessel contains one or more horizontal filtering chambers placed over the receiver, and the filters are filled with clean cotton waste. A funnel is attached to the receiver, and the oil passes from the filters through the funnel into the receiver. In the funnel are a series of sieves, which catch the dirt. Taps are placed at the lowest extremity of the filter and receiver, in order to draw off the dirty oil and the clean oil respectively. The apparatus may be made of tin or of wood. Three claims are made for this apparatus.—No. 6756. May 9th, 1887. 6*d.*

GAS FURNACE FOR GLASS MELTING.—*J. Yelland, York.*—In constructing a combined pot and tank gas furnace, the inventor forms pockets or reservoirs at each side of the lower part of the structure for the gas to pass into. Towards the inside of the furnace, and near to these gas pockets, are metal or glass pockets for the reception of waste glass or metal. Further inwards are air pockets, from which the air is passed in circulation through the furnace and through the air flues between these pockets. Above these pockets is the furnace proper, over which is placed a series of platforms, tanks, and pots, which contain the ingredients for making the glass. In the upper part of the frame work and between the pots are several gas purifiers in the shape of small clay crucibles with holes in their centre. The gas passes from one of the gas pockets through a valve into the pot, thence through the purifiers and into the other gas pocket. The air passes under the "seige," and is consequently made much hotter than in ordinary furnaces; afterwards it is taken back through an air box to the furnace. By placing the metal or glass pockets one between each gas and air chamber the depth of foundation is considerably reduced, and the furnace is made more effective. The mixed gas and air is lighted at the entrance to the furnace "seige," and travels across the tank to the other gas and air ports between the pots and tanks, where there is a flue for cooling the various surrounding parts. The inventor makes one claim.—No. 2948. February 25th, 1887. 8*d.*

GERMAN PATENT ABSTRACTS.

LIQUID FUEL.—*Aerated Fuel Company, Hampden County, Mass.*—This invention relates to an improvement in boilers heated with liquid fuel. The boiler is provided with a diaphragmatic



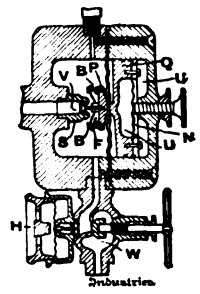


plate A and a number of tubes B. The liquid fuel is stored in a tank C, and forced against the tubes B by means of an air pump E F through the tube D, which is fitted with a nozzle. Out of this nozzle the liquid escapes in form of spray, and is ignited by a small flame burning inside the boiler. If the steam pressure in the boiler exceeds a certain limit the steam is cut off by the valve G from the cylinder E of the air pump F, thereby stopping the supply of fuel until the steam has again assumed the normal pressure, when G is opened, and the air pump actuated.—No. 42690. July 6th, 1887.

REDUCING VALVE.—*G. Fulda, Berlin.*—This valve is intended to use gases or liquids stored at high pressure in a tank at an even and lower pressure. The valve V, with the seating S, is

connected to the piston Q, which is provided with the diaphragm N. The connection between V and Q is effected by a spring arrangement F B B P. The tension of the diaphragm N may be regulated by a screw and two air cushions U U, and by altering this tension the amount and pressure of gases or liquids passing through V in a given time may be controlled.—No. 42335. February 20th, 1887.

UNITED STATES PATENT ABSTRACTS.

INCRUSTATION OF BOILERS.—*J. Mullica & B. F. Mullica, Williamstown, New Jersey.*—The inventors have discovered an improved composition for removing and preventing the incrustation which forms in the interior of boilers. Sand is prepared by burning, grinding, and washing, and is combined with powdered charcoal and elm bark in certain proportions. This combination, when applied to the interior of the boiler, is claimed to have the desired effect. One claim is made.—No. 380340, dated 3rd April, 1888.

CIRCULAR KNITTING MACHINE.—*L. E. Salisbury, Providence, Rhode Island.*—These improvements are applicable to the mechanism for knitting plushing threads over the front and back of the wales of a knitted fabric. Two needle carrying cylinders revolve together, and a needle shunting wheel is placed in each cam section, in order to guide the needles alternately to the upper and lower cylinders. Needles of a specially designed shape retain the loops of the fabric while passing one cam section, and there is also an improved yarn guide and stopping device provided. There are eight claims.—No. 379819, dated 20th March, 1888.

CARBONISING VEGETABLE MATTERS IN WOOL.—*C. Schrebler, Methuen, Massachusetts.*—The wool is first treated with a weak acid solution, and afterwards a current of warm dry air is forced through the entire mass; the wool is thoroughly dried by this air. A second current of air is subsequently drawn through the wool; this air is heated to a temperature of 180°F., and serves to carbonise and destroy all vegetable matter which is contained in the wool. Two claims are made.—No. 380599, dated 3rd April, 1888.

PAPER FOR WRAPPING METALLIC ARTICLES.—*J. C. Pennington, Paterson, New Jersey.*—This new article of manufacture has been designed for the purpose of preserving metallic articles from rust and tarnish when they are stored. On the surface of the wrapping paper is incorporated a coating of finely powdered zinc. This coating is found to prevent the surface of the metal with which it is in contact from tarnishing and rusting. Two claims are made.—No. 380516, dated 3rd April, 1888.

FEED FOR CLOTH FINISHING MACHINES.—*J. J. Scholfield, Providence, Rhode Island.*—The mechanism consists of a pair of obliquely set spur belts, with or without superimposed spur rollers, for pressing the fabric upon the spurs of the belts. The belts are preceded by temple rollers held in pivoted frames, which are swung by the traction of the cloth whenever it runs to one side or the other; the cloth is thus caused to travel in an approximately true line to the finishing machine. The temple roller may be operated by regulating mechanism, and power dispensed by the machine, instead of by the tractive force of the cloth. Four claims are made.—No. 380139, dated 27th March, 1888.

TREATING ZINC ORES.—*C. F. Croselmire, Newark, New Jersey.*—The ores are first pulverised and roasted in a furnace; during the latter operation a blast is passed through the ore. Afterwards the roasted ore is immersed in dilute acid, and another blast is passed through the solution until all the impurities are oxidised. The zinc solution is finally drawn off, and the zinc is precipitated in the usual way. Two claims are made.—No. 379764, dated 20th March, 1888.

The full specifications of the British and United States patents, and the Official Journals of the German Patent Office, from which the above abstracts have been compiled, and the Official Journal of the United States Patent Office, may be seen by subscribers and clients at the Reading Room, Manchester Office of INDUSTRIES, *where also Patent Indexes from* A.D. 1617 *may be consulted. Copies of the British specifications may be obtained on application to* H. READER LACK, ESQ., *Comptroller-General, Patent Office, Southampton Buildings, London, W.C. The published price must be remitted, together with a sum sufficient to cover postage, which may be reckoned at* ½*d. for every* 10*d. or fraction of* 10*d. Remittances exceeding one shilling must be made by Post Office Order.*

GLASGOW INTERNATIONAL EXHIBITION.

One of the important exhibitions of the year is that of Glasgow. In October, 1886, the initial steps of the undertaking were made, premiums were offered for plans, a design was selected—the successful competitors being Messrs. Campbell, Douglas, & Sellars—and on the 2nd May, 1887, the first sod was cut. The elevation of the buildings was illustrated by us in our issue of 13th May, last year, and a plan of the grounds in our issue of 11th November. The site offers unusual advantages. The main building of the Exhibition occupies a broad level stretch of ground on the south bank of the Kelvin, directly opposite the University, and the river cuts the Exhibition grounds into two nearly equal parts. The main building covers almost the whole disposable area on the south bank, while the north slope of the Kelvin is partly in grass plot and partly occupied by buildings. Access is obtained to this portion of the grounds from the main front of the Exhibition by two bridges; one a permanent iron bridge, the other a temporary wooden structure, with parapet of a design in keeping with the design of the buildings. Directly opposite the centre of the main front are the fairy fountains, supplied by Messrs. W. & J. Galloway and Sons, of Manchester. The manipulation of the fountains is effected from a tower erected near the river, and the pumping engines and dynamos are situated in an engine house on the south bank, the pipes and wires being conveyed across the Kelvin over a trestle bridge. It is understood that Messrs. Galloway have considerably improved the design of the fountain since they manipulated it at Manchester and that several novel effects will be shown. On either side of the bridges, and between them and the fountains, are large and gaily decorated kiosks, to be tenanted one by a confectioner and the other by a tobacconist. On the lower slope of Gilmorehill, immediately under the University, is a reproduction after the manner of "Old London" and "Old Manchester," though on a much smaller scale, representing the Bishop's Palace, a mediæval building which was removed at the end of last century to make way for the Royal Infirmary. This building contains an archæological collection, and forming as it does a museum of curiosities of interest in Scottish national history and antiquities, is one of the attractive features of the Exhibition. Disposed on the slopes of Gilmore-hill are several refreshment rooms, the architecture of which, differing as it does in each case, is in keeping with the general character of the design of the main buildings. The high north bank of the Kelvin, crowned by the University, offers a number of striking views of the whole of the buildings of the Exhibition, and this constitutes one of the chief advantages of the situation. In addition to the external attractions already mentioned, there is in the angle formed by the main building and the machinery annexe, a fountain erected by Messrs. Doulton & Co., London. This fountain will become the property of the Corporation of Glasgow after the Exhibition is over. It is built of terra cotta, the design representing symbolically the British Empire. A statue of Her Majesty crowns the fountain, and the niches below are occupied by groups representing the characteristics of our Colonial dependencies. In the Kelvingrove Museum, a permanent building situated in that portion of the Kelvingrove Park which has been included within the green boarding of the Exhibition grounds, have been placed the Queen's Jubilee presents. When the Exhibition opens, these will then be on public view for the last time. It is understood that they will be removed to Windsor permanently in November next. The cabinets, illuminated addresses, gold boxes, umbrellas of ostrich feathers and other examples of barbaric and semi-barbaric magnificence which compose the Jubilee presents, have often been described. On the north side of the river, and hidden from view by the high banks, there is a double switchback railway connected with the other side of the river by a low trestle bridge built by the 1st Lanarkshire Engineer Volunteers. From the grounds the main entrance to the Exhibition building is by the transept. On either side of the doorway are the Royal reception rooms, and on passing these we then enter under the great dome in the centre of the main avenue. The view right and left from this view point is unfortunately much impeded by the height of some of the exhibits; but it is, notwithstanding, impressive enough. The space under the vault of the dome is occupied by a fernery and fountain, and to this the dome itself, with its prevailing tints of red and yellow, offers an effective contrast. The spring of the vault is decorated with four round panels, upon which are painted symbolical figures of industry, science, art, and agriculture. These decorative panels are by four young Glasgow artists, Messrs. Guthrie, Henry, Lavery, and Walton, and form an important and successful feature in the scheme of decoration.

Eastward and along the main avenue are the large and attractive exhibits of the section of naval architecture. These will hereafter receive special description; but

GENERAL PLAN OF GROUNDS SHOWING THE ELECTRIC LIGHT CIRCUITS.

meantime there may be noted the two-storeyed saloon and music room shown by Messrs. Denny Brothers, Dumbarton. The wood work and fittings of this cabin are such as are placed in the highest class of passenger steamers, and offer an excellent example of substantial workmanship and superior design. The stands of Messrs. R. Napier & Sons, Alexander Stephen & Sons, the Fairfield Shipbuilding Company, the London and Glasgow Shipbuilding and Engineering Company, Lobnitz & Co., D. W. Henderson & Co., J. & G. Thomson, A. J. Inglis, Wm. Simons & Co., and Palmer & Co., are all extremely interesting; and, along with some models familiar to Exhibition visitors, show many examples of the most recent developments of naval architecture. The section includes other exhibits in the side avenues, and taken as a whole is, as one should expect in one of the chief homes of shipbuilding, an exhibition of great scientific and historical value. Eastwards, also, along the main avenue one finds the large cases of textile exhibits of Messrs. Horrockses, and Copland & Lye, the trophy of Messrs. Clark and Company, of the Anchor Thread Mills, Paisley.; the model mill and electric spooling of Messrs. J. & P. Coats; and the immense panelled erection upon which Messrs. J. & J. S. Templeton & Co. display their carpets. When we come to estimate the value of the Exhibition as a school of design, we shall have occasion to notice very specially the achievements of Messrs. Templeton as leaders in the development of artistic industry. Messrs. Templeton's rather too lofty case forms the western limit of the grand hall. At the opposite end is the orchestral and choral platform and the organ. This instrument is by Messrs. J. W. Walker & Co., of London. On either side of the grand hall are arranged the exhibits of the photographic section. Parallel with the hall, and occupying the south-east corner of the buildings, are the picture and sculpture galleries, and at the north-east corner are the courts devoted to the women's industries section. The exhibits in the picture galleries are in two divisions—the loan collection and the collection of works for sale. In the former, many well known pictures have been lent by private owners and by public galleries. In the fine art section the international intention of the Exhibition has been kept in view, and probably more successfully achieved than in some of the other sections. The collection of the products of women's industry has been the result of a vast amount of labour. Preliminary exhibitions have been held in a number of local centres, and from these exhibitions selection has been made of the best exhibits. This has involved an immense amount of organisation. The result can hardly yet be estimated, since comparatively few of the exhibits are unpacked. The courts to the left of the main avenue, as one turns again westwards, are occupied by the education section, in which the exhibits of the Glasgow and West of Scotland Technical College, and of the Glasgow School Board, are prominent; the chemical industries section, in which the Tyneside case is conspicuous; the exhibition of scientific instruments, in which Messrs. James White, who show Sir William Thomson's syphon recorder, compass, and sounding apparatus; Baird & Tatlock, George Mason & Co., and McGhie & Bolton have large and interesting cases. In these courts also there are the exhibits of the agricultural section, the artisan section, and the jewellery section, in which the stand of Messrs. Edwards & Sons, in the south transept under the dome, is specially interesting, since they show a number of historical presentation caskets and swords, which have been made by the firm. Here also is the carriage section, and the exhibits of the mining and metallurgical section, in which the Tharsis Sulphur and Copper Company show enormous ingots of copper, and other specimens of their manufactures. The courts to the right of the main avenue looking westwards are occupied by textile exhibits, leather manufactures, by musical instruments, and by furniture. In the latter class the rooms fitted by Messrs. Wylie & Lockhead, Bennett, and Balfour, are instructive examples of local decorative skill. In these courts also is the Indian exhibit, the largest and most important of the foreign collections. At the extreme west end of the main avenue, and placed at right angles to it, is the machinery annexe. At the junction between the annexe and the main avenue is the large exhibit of Messrs. Walter Macfarlane & Co., of the Saracen Foundry. This consists of a number of very large pieces of cast iron work—a fountain, gateways, &c. Next to it are four immense steel exhibits. These are the exhibits of the Steel Company of Scotland, Messrs. David Colville & Son, the Hadfield Steel Company, and Messrs. Cammell & Co., both of Sheffield. The copper exhibit of the Birmingham Battery and Metal Company, and the large cast iron trophy of the Sun Foundry, are at the avenue end of the machinery annexe. The annexe is capacious, and the exhibits are not unduly crowded. A gallery runs round the walls, and on this there are disposed some of the lighter machinery exhibits—beltings, for example. In the first line of machines are those connected with paper and printing. Messrs. Mollison and Co. print upon a machine made by Mr. Alexander Seggie, of Edinburgh, and the patent folder of Messrs. F. Martini & Co., of London, is exhibited with newspaper wrapping and bookbinding machinery by Mr. W. C. Horne, of London. In the same line are the exhibits of Messrs. J. Greig & Son, Miller & Richard, and Andrew Elliott, all of Edinburgh. In a general view of the machinery section, among the most prominent exhibits are the sugar machinery and powerful engines shown by Messrs. Mirrlees, Watson, & Co.; the large engine shown by Messrs. D. Adamson & Co., of Dukinfield; and the 100 h.p. engine shown by Mr. John Cochrane, of Barrhead. This last engine is fitted with Corliss gear, and the fly wheel is arranged for nine groove rope gearing. The rope used in this case is a novelty. It has been made by Messrs. John Tullis & Son, and consists of a combination of wood and leather. Important positions are also occupied by the tubes exhibited by Messrs. A. & J. Stewart, Coatbridge; by the furnaces of the Leeds Forge Company; the corrugated iron flues shown by the Farnley Iron Company, Leeds; and by the patent hydraulic mangle shown by Messrs. Urquhart, Lindsay, & Co., of Dundee. Besides the stand of the Birmingham Battery Company already noticed, the copper exhibits include the copper pipes and cylinders shown by the Broughton Copper Company, Manchester, and the distilling plant shown by Messrs. J. Miller and Co., Glasgow. In addition to the steel exhibits already mentioned, there is the exhibit of heavy forgings of Messrs. Beardmore, of Glasgow; and among the miscellaneous exhibits are those of Messrs. Tullis & Son, who show belting and belting machinery; Messrs. R. & J. Dick, who also show belting and belting machinery; the patent disintegrator of the Disintegrating Grinding Machinery Company; the carpet weaving machinery of Messrs. W. & G. Millar, Glasgow; and the working confectionery plant of Messrs. John Gray & Co.

In describing the plant in the dynamo room in last week's issue we noticed the fact that the shafting is driven by rope gearing. The belting by which the dynamos are driven is the canvas belting of the Rossendale Belting Company, and is fastened by Jackson's patent fastener.

Among prime movers, in addition to the engines mentioned above and in our issue of last week, there is the marine engine of Messrs. Ross & Duncan, Whitefield Works, Govan. This is the only marine engine of full size in the Exhibition, and is accordingly specially worthy of honourable mention. It is of the triple expansion type, 400 i.h.p., is fitted with the Bremme valve gear, and is attached to a Duncan's patent propeller. There are also engines of various types shown by Messrs. Tangye and Co., Birmingham; Alley & Maclellan; Sharp, Stewart, and Co., and J. Goodwin & Co.

The central avenue of the machinery section is fitted with an overhead crane, supplied by Messrs. George Russell & Co., Motherwell, and the heavy exhibits have all been placed without mishap.

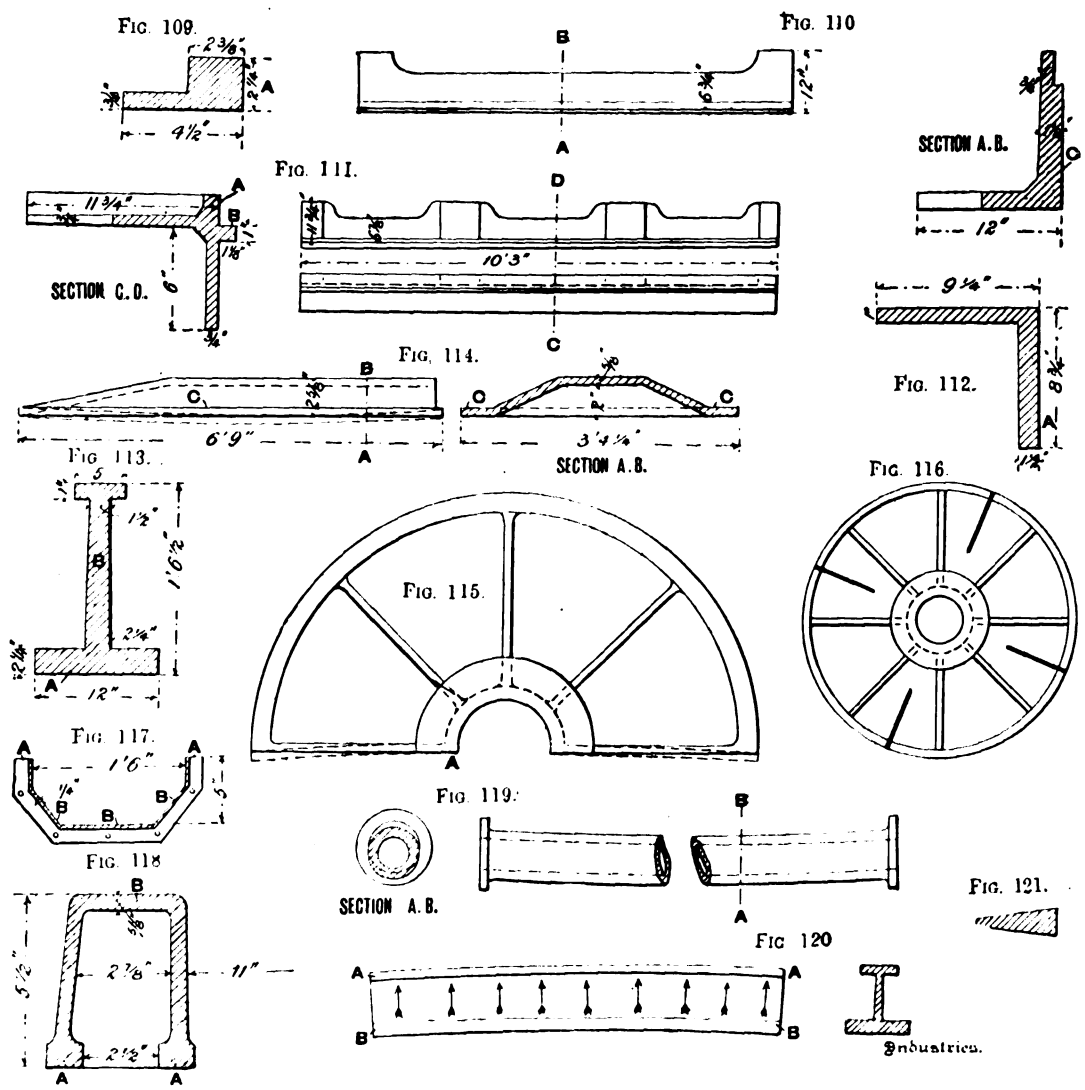
Our illustrations this week show the internal arrangements of the buildings and grounds, and the wiring arrangements of the electric light installation. It will be observed that the grounds are lighted by three circuits, in which there are respectively fifteen, fourteen, and five sets of lamps. Fifteen of these are on 60ft. masts, the remainder being erected upon 25ft. poles. The arrangement of the leads in the interior of the buildings will be readily understood by reference to the plan. The whole of the engineering arrangements have been carried out under the superintendence of Mr. W. A. Bryson. On Saturday last, the Executive invited the Press to a preliminary view of the Exhibition, and upwards of 120 journalists from all parts of the kingdom availed themselves of the invitation, the leading London, and many of the foreign, newspapers being represented. The Exhibition will be opened on the 8th May by the Prince of Wales, and this day will be held in Glasgow as a public holiday.

NOTES ON FOUNDRY WORK.

BY THE AUTHOR OF "PATTERN MAKING."

(Continued from page 237.)

XIV.



THE CURVING OF CASTINGS.—In the last article the shrinkage of castings was dealt with, and the present one will be devoted to an equally important subject in foundry work, viz., the curving of castings. It is very difficult even for experienced founders to judge how and to what extent an ill proportioned casting will curve, since slight alterations in the disposition of the metal may materially assist in producing or preventing curvature. I will now briefly consider the conditions which affect the curving of castings, and then give some typical examples selected from my own experience.

As a rule castings will show a curve in those places where the amount of metal is considerable. In some cases, however, those portions which cool most rapidly curve most. The harder the iron is the greater is the tendency to curve. Figs. 109 and 110 show two plain castings 10ft. 6in. in length. In these castings the metal is considerably thicker in the places marked A and C, and in each case the sides A and C showed a curvature of $\frac{1}{4}$in. Fig. 111 shows the bottom sill of a hatch or sluice. Both flanges are $\frac{3}{4}$in. in thickness, but the ribs A and B are thicker than the flanges. These ribs occasioned a curvature of $\frac{3}{8}$in. along the face A, and of $\frac{1}{4}$in. along the face B. Fig. 112 shows a stanchion 11ft. 9in.

Digitized by Google

long, with a uniform section throughout, in which the flange A is $\frac{1}{2}$in. thicker than the other flange, and the larger amount of metal on that side produced a curvature of $\frac{3}{8}$in. These examples illustrate the fact that castings curve in those parts which contain the greatest amount of metal. This rule, however, is subject to modifications in cases where the castings are sufficiently rigid to resist the internal strains which tend to curve them. Fig. 113 shows the section of a girder 18ft. long, which was expected to curve at A, hence the bottom flange of the pattern was curved $\frac{3}{8}$in. The first casting, however, was exactly like the pattern, and after substituting a straight pattern the castings showed no curvature. I was unable to account for the absence of curvature, especially as a set of girders of a similar but rather heavier section had been made a short time before, with lengths varying from 22ft. to 26ft., and these all curved from $\frac{3}{8}$in. to $\frac{1}{2}$in. along the heavy flange, so that the pattern had to be curved to the same extent. As the girders just mentioned and the one shown in Fig. 113 were cast in the same foundry by the same methods, and were not uncovered until the next morning, I assume that their different behaviour as regards curvature is to be attributed to the relative disproportions in length, and to the different disposition of the metal. The web B of the girder shown in Fig. 113 is 1ft. $2\frac{3}{4}$in. deep, and it would require an enormous strain to curve it in the direction of its depth. The average thickness of this web is $1\frac{3}{8}$in., against $2\frac{1}{4}$in. of the flange, so that the section of the web equals 28 sq. in., while that of the flange only equals 27 sq. in. The web offers, therefore, by reason of its depth and area, a great resistance to the curving force in the bottom flange. The smaller flange has such a light section that it need not be considered at all, so that only the relative proportions between the web and the bottom flange have to be ascertained. Light castings are more apt to curve when disproportioned than heavy ones, and heavy engine bases, especially if stiffened with ribs, do not curve appreciably, while narrow and light beds curve considerably. The buckled plate, shown in Fig. 114, may be taken as a good illustration of this fact. The pattern was straight along the flange C, but the first casting showed a curvature of $\frac{1}{2}$in., assuming the shape shown by the dotted line. The body of the casting being one solid mass of metal, cooled more slowly than the flanges, and continued shrinking after the flanges had partly set, thereby curving them. This example confirms the previous remarks I made, that light castings are more liable to curve than heavy ones, and it also illustrates the tendency of a light plated casting to buckle or curve in any direction. Thus, plates cast in open sand will often curve or dish upwards, as the top surface cools more rapidly, and thereby curves the other surface. In a covered mould, however, a plate may in some cases curve downwards. It appears that there is much analogy between the buckling of cast plates and that of sheet metals, the castings while red hot being plastic, and while in that state accommodate themselves to the strain. In the case of Fig. 114 the flange was curved by the shrinkage of the buckled portion alone. But when the curve was imparted to the flange in the reverse direction, it resisted that buckling tendency; the flange, when partially solidified, acting like an arched spring. There is, probably, a curve which would have counteracted the bending tendency of the buckled portion, and the casting would have been, if I may use the term, in a condition of equilibrium as regards the strains set up by solidification; but a little initial movement in one direction would have caused curvature in that direction. A further illustration of the buckling of a circular plate is furnished by the tank bottom shown in Fig. 115. The metal in the plate is $\frac{1}{2}$in. thick, and the diameter of the tank 9ft. 2in. To obtain a straight joint at A in the casting the pattern was curved, as shown by the dotted lines, demonstrating very clearly the excess of shrinkage of the parts near the circumference over those nearer the centre. These tank bottoms were formerly cast in one piece instead of being jointed, but the plates were sometimes fractured in a radial direction by the excess of shrinkage near the circumference. Then four slots, $\frac{1}{4}$in. wide, were cast in the plate, as shown in Fig. 116, by means of metal splitting plates. These slots widened in cooling, allowing the plates to fall out, and they were afterwards filled up and rendered water tight by caulking with borings and sal-ammoniac. This effectually prevented fracture; but still better results were obtained by casting the plates in two pieces and planing the joint, making due allowance for shrinkage near the circumference by curving the joint face A as shown. Castings like those shown in Figs. 117 and 118, illustrate the same fact as Figs. 109-112. Fig. 117 shows the section of a gutter 7ft. $4\frac{1}{4}$in. long, which required a curvature of $\frac{5}{16}$in. along the edges A A of the pattern, in order to produce straight castings. The edges A A, being thin, cool almost immediately; but the sides and bottom B B B take considerably longer, and would, if the pattern were made straight, curve along the inside bottom face, thereby also curving A A. An engine bed of the half section shown in Fig 118, which was 11in. between the sides and 9ft. 6in. long

NOTES ON FOUNDRY WORK.

required curving $\frac{3}{8}$in. at A A to make the casting straight. Ordinary tank plates, 4ft. square and $\frac{1}{16}$in. thick, curve about $\frac{3}{8}$in. on the side opposite to the flanges. The greater the disproportion between these parts, that is, for example, between the plate B and the ribs A A, Fig. 118, the greater the amount of curvature. If the casting were symmetrically plated at the top and bottom it would not curve at all. Fig. 119 illustrates an apparent exception to the cases hitherto given, as it represents a column which has curved in the direction of the least mass of metal, the metal being thinner at the top than at the bottom. The metal in a column being equally thick all round, curving upwards will take place if the cope be removed while the casting is still hot. A very slight difference in thickness, however, suffices to curve light castings. We may assume that curving is due either to difference in the amount of metal or to unequal rate of cooling, for it is obvious that if a casting be equally proportioned and cooled equally, as, for instance, a column in which the core is perfectly central, the heat radiates equally all round, and the casting will be quite straight. When a disproportioned casting like that shown in Fig. 109 is poured, one part—the thinnest—cools first, the thicker parts cooling afterwards. The extent of shrinkage of the parts which cool first varies, being influenced by the adjacent amount of metal. That part of the casting which cools slowly is, to a certain extent, held by the part which is solidified, and is therefore not free to contract regularly. The whole casting will therefore assume a shape which is determined by the proportions of the casting. In the examples shown in Figs. 109 to 113 the casting has curved in such a manner as to shorten the heavy flanges, while we have shown before that heavy castings shrink less than light ones. In Fig. 120 the distance from A to A is greater than the distance from B to B, yet as regards shrinkage only the distance from A to A should be shorter than from B to B. In this instance we must consider what takes place when the metal is poured into this mould. The cooling of this casting is of a complicated character, as the light and heavy masses of metal influence each other by means of the web, which transmits the heat. The thin flange soon becomes partially set, but not rigid, as it is supplied with heat from the more massive flange and web, in the manner indicated by the arrows. Its shrinkage is thereby delayed and diminished, but not sufficiently, as the heavier flange continues to shrink after the light one has finally set, and there is nothing to diminish its full shrinkage. The heavy flange therefore becomes shorter than the other one, and the casting assumes the shape shown in Fig. 120. In a casting of the section shown in Fig. 121 the process just described is more regular than in any other section. As we explained before, a casting of the shape shown in Fig. 119 is liable to curve upwards if the metal be of unequal thickness, or one side of the casting be exposed to the air. In this case the disproportion in thickness or in rate of cooling cannot be very great, as the metal is thin, and the heat radiates at once. There is not sufficient heat to influence conductively, and the initial curving remains permanent. If a bent casting placed on end supports be made red hot by a fire underneath, and then weighted, it will in some cases become straight. Near the outside of the casting, which sets rapidly, the crystals are small, while the inner parts, which cool slowly, crystallise in larger prisms, and when the mass of metal is very large, actual cavities will often occur in the casting. Hence the use of "feeder heads," by which the supply of fresh metal is maintained to "feed" the mass until solidification occurs.

The main point to be considered, in order to prevent the curving of castings, is to make all parts cool uniformly in proportion to their mass. This, of course, cannot always be insured; but a moulder may sometimes do much in this direction by opening out and cooling the heavier parts, or by taking the casting out of the mould while still hot, and putting it on supports and weighting it. Other precautions are to swab, weight, or pack up the casting; but in all these operations the casting has to be constantly watched until it is nearly cold, since curving and shrinkage will go on, even when the metal is black hot. Wherever it is practicable, it is safer, however, to make provision beforehand by curving the pattern, and then allow the casting to remain *in situ* until quite cool.

(To be continued.)

THE MANCHESTER ROYAL JUBILEE EXHIBITION.

Textile Machinery.

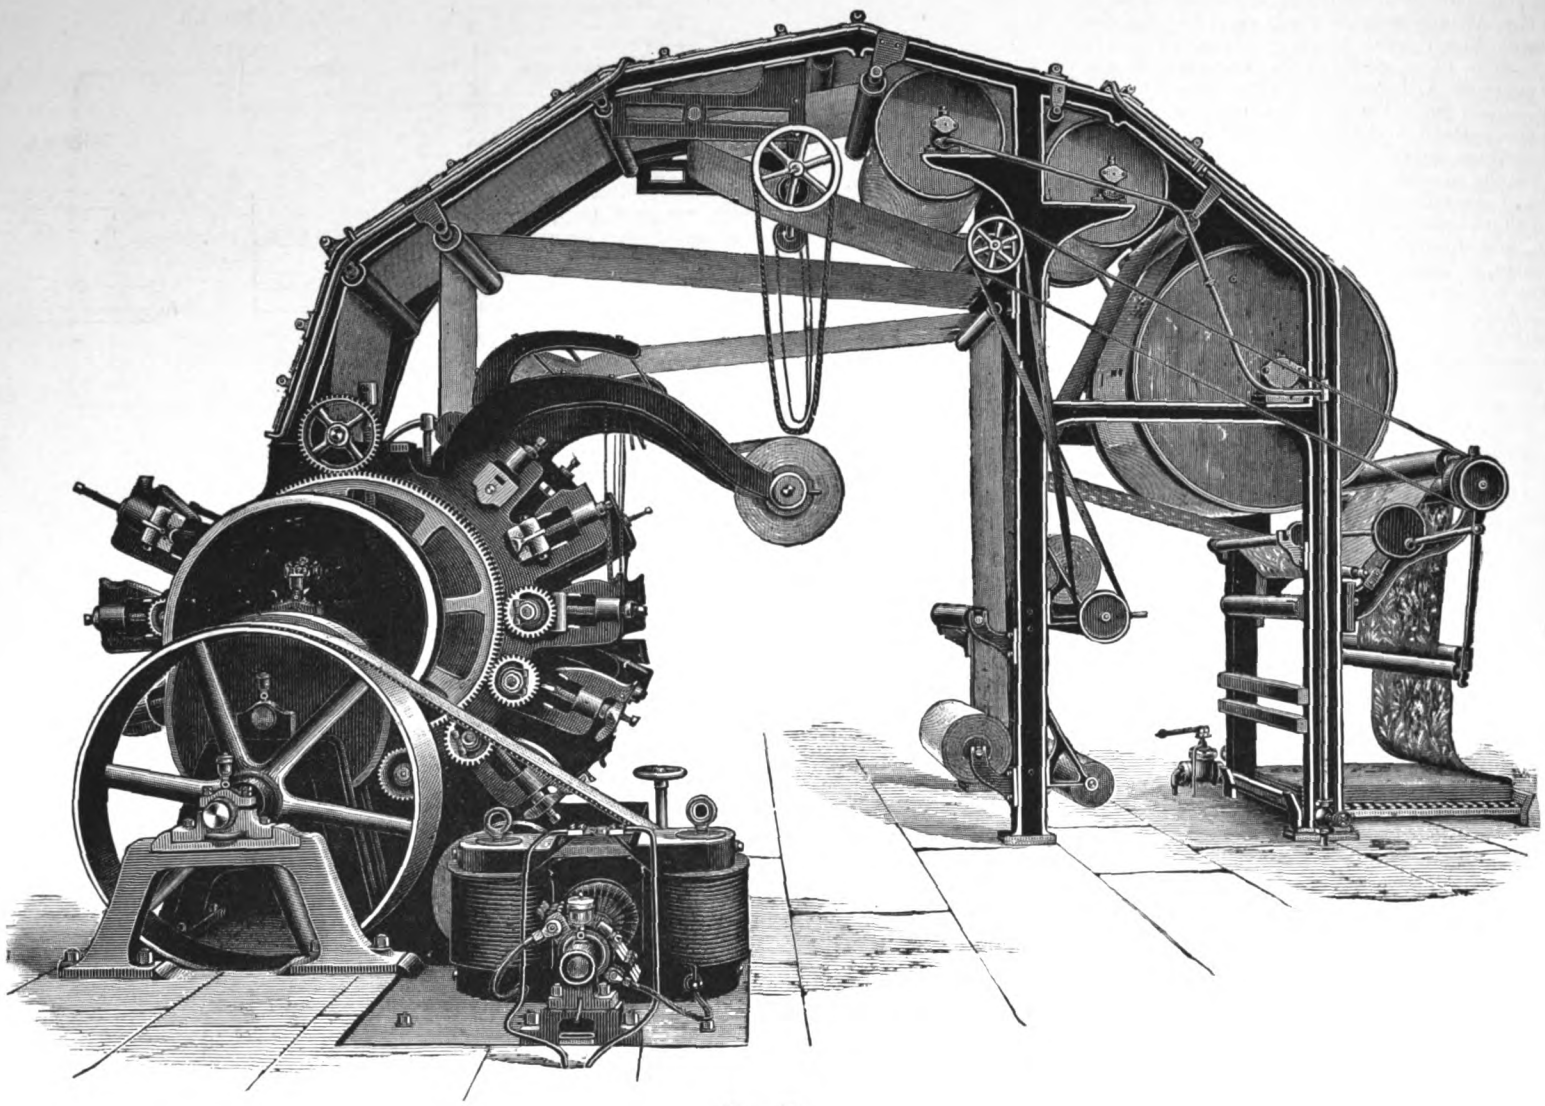

Fig. 73.

THE MANCHESTER ROYAL JUBILEE EXHIBITION.

Textile Machinery *(concluded from page 393)*.—The cloth having been produced, may be treated in various ways, according to the class of fabric it is desired to manufacture. A printing machine for ten colours was exhibited by Messrs. Mather & Platt, Salford, Manchester, of which we give an illustration in Fig. 73. As it did not differ materially from those of ordinary construction, it does not require any special description. The most interesting feature in connection with this machine was that it was driven by an electric motor. Mr. William Birch, Broughton, Manchester, to whose exhibits we briefly referred in our last issue, exhibited an open soaping machine, shown in Fig. 74, intended for the cleansing of fabrics after bleaching or printing. When the cloth enters the machine it is passed over a scutcher or revolving beater, thus having the creases taken out, the straightening process being aided by its subsequent traverse over an angular guide. An expander, which is formed of a number of grooved discs placed on a shaft, next receives the cloth, the discs being of different diameters, so that each set forms a truncated cone, the tops being placed together. Special provision is made for the bearings of this shaft, in order that it may run with very little friction. It is not absolutely essential that these appliances should be affixed to the soaper, they being more used in connection with drying machines. The soaping machine is constructed in the usual way, with a trough containing the scouring liquor in which the rollers are immersed. The cloth is passed round these rollers and others carried in a frame, and thus travels several times through the liquor. The lower rollers are constructed in a peculiar manner, so that the water is forced through the fabric, thus effectually scouring it, as shown clearly in Fig. 74. The body of the roller has radial grooves formed in it, in which bars extending longitudinally are placed. On the roller shaft at each end of the roller are plates formed with internal grooves, in which the ends of the bars referred to are made to slide. All the bars have near their ends a slot, through which passes a ring which holds them together. The width of the bars added to the diameter of the ring is such that the edges of the bars will always project a little beyond the surface of the roller. If the bars are pressed at one side, the recesses in the roller allow them to lift, so that those on the other side of the roller project much further than when no pressure is exercised. In this way, when the cloth is passed round the roller, it lifts the bars until the edges of those which are lowest are level with the body of the roller. As the revolution of the roller takes place and the bars come alternately in contact with the cloth, a small volume of water is confined between the bar engaging the one which has preceded it and the cloth. The continued revolution of the roller causes the bar to move upwards in the way explained, and, consequently, the water being unable to get away, is squeezed through the interstices of the cloth, which is thus thoroughly washed. This is a very ingenious device, and worthy of special notice. As all fabrics in their course through machines of this class have a tendency to gather in the centre of the machine and form a rope, it is necessary in some way to counteract this, the preservation of the open condition being most essential for success. Mr. Birch employed a specially constructed conical expander. This consists of two truncated cones of copper or brass, fixed on adjustable shafts, and fluted or corrugated on their outer surfaces. The form of the flutes is such that the tendency is to grip the cloth firmly and pull it away from the centre. The cloth is passed over the rollers, by setting which it can be drawn to either side of the machine, and can be stretched in the direction of the width as much as desired. After being thoroughly scoured and washed, the cloth is taken between a pair of squeezing rollers, and then under a tension roller connected with the strap guide, so that any increase or decrease in the amount of tension is followed by a similar variation in the speed of the machine. A relieving motion is also fitted, in order that the tension may be taken off the cloth if it is necessary to handle it.

Messrs. Jas. Broughton & Co., Manchester, exhibited a three-bowl calendering machine, which was of very strong construction and powerfully geared. The driving was effected by means of a friction clutch, put into operation by worm gearing. Special arrangements for weighing and relieving the bowls were provided, and taken altogether, the machine was a very fine specimen of its class. In addition to this exhibit, one or two bowls made of cotton and paper were shown, the former being partially finished, in order to illustrate the method of construction.

Mr. John Oliver, Manchester, had a small but very complete exhibit of the materials used in the construction of calender bowls, and also of the finished articles. The materials comprised coir, cotton, paper, linen, and wood pulp; the latter being now very largely used by Mr. Oliver, and is obtaining an increasing sale. A specimen bowl made of this material was very finely finished, and appeared to possess all the properties which are essential to success in this direction.

Before closing these articles it is necessary to briefly refer to the various exhibits of accessories which are used in this connection. Several cases of spindles and rollers were shown, in which examples of all varieties of each were fully illustrated. Not the least interesting feature of this display consisted in the advance shown in the methods of construction, the use of special tools being now much more general than formerly. As the various kinds of spindles are commonly understood, and some of them have been described, it is not necessary to make any further reference. Messrs. Wilson Brothers, Todmorden, had a very complete case of bobbins of various shapes. The noticeable feature in this case was the extensive use which is made by the firm of metallic shields applied to the top or the bottom of each bobbin, so as to prevent damage. There is also a special throstle bobbin shown, lined with a metallic tube, by which the saturation by oil which often occurs is prevented. A thin metallic binder applied to the heads of winding or warper's bobbins is also a valuable feature. This forms a tyre or hoop, and binds together the two portions of the flange or head of the bobbin, and at the same time

Digitized by Google

protecting it from breakage. Messrs. Wilson & Sons, Barnsley, Messrs. Irvin & Sellars, Preston, and others also had complete show cases of bobbins. Mr. R. Pickles, Burnley, exhibited his patented compressed wood shuttles, which are made of ordinary woods, the blocks of which are subjected to a hydraulic pressure of 20 tons to the square inch. In this way the density and tightness of the wood is greatly increased, and wood such as ash and beech can be used with great success.

Several samples of card clothing were shown by Messrs. Horsfall & Bickham, Manchester, Messrs. J. Walton and Son, Woodley, and Messrs. Wilson & Ingham, Liversedge, which together showed clearly the immense advance made in this material latterly. Several cases of paper tubes used in spinning were exhibited, and Messrs. Swailes & Son, Oldham, exhibited a patented machine, which enables a mule to be re-tubed in much less time than is possible by hand. It is not possible or necessary to do more than refer to the fact that roller leather, banding, and the numerous accessories used in spinning and weaving were all fully exemplified.

Among the minor appliances which were shown may be mentioned Staub's yarn balance, exhibited by Messrs. G. Thomas & Co., Manchester. This ingenious little instrument enables the counts of yarn in the warp or weft of cloth to be readily ascertained, this being accomplished as follows: A little square of the material, corresponding in size to a small template which is supplied with the balance, is cut out of the cloth. The threads are drawn out of the square and placed in a hook suspended at one end of a light lever, which is sustained in a special manner. As soon as the lever balances, which can be easily seen at a glance, the number of threads placed in the balance are counted, and correspond to the counts of yarn employed. Yarn indicators and testing machines were shown respectively by Messrs. Goodbrand & Holland and Messrs. Wallwork & Co., both of Manchester.

In concluding our notice of the textile machinery at this Exhibition, we are conscious that there are many exhibits to which a longer notice could be given; but the most important and typical ones have been fully noticed. The object of these articles has been to indicate the latest developments in textile machinery as shown, and in this way to create a record which would be valuable to our readers. It will be many years probably before such a complete illustration of this class of machinery will be again given, and the full details which we have furnished will then be of value to the student and manufacturer.

(To be continued.)

BERDAN'S COMBINED RAM AND TORPEDO.

The object of the system proposed by General Berdan is the defence of the coasts from an enemy's ironclad; he proposes to attack and destroy them while still out of range of the land, and in spite of any means of defence they may possess. The system consists of a ram with bows at either end, 250ft. long, 24ft. to 36ft. beam, 14ft. to 16ft. draught, and four engines, each of 1500 i.h.p. Each engine is to drive a separate propeller, two at either end. At each end are also two torpedoes, and a spur 6ft. long. The spur is to be protected, when in contact with a ship at a greater angle than 45°, by a guard like that used in ferry boats. The screws are to be placed under these guards. There are to be four rudders, each to be placed in front or outside of a screw, and supported by the bracket that supports the screw shaft. The two rudders at either end to be connected, and operated by one helm. There are to be four funnels, which can be telescoped by machinery when making an attack. There is to be a conning tower, and the bows are to be plated and protected by guards made of steel beams placed edgewise, leaving spaces for the water to splash through. There will be two levers at either end of the ram for operating the torpedoes, which will be attached to the outer end, whilst the other end is keyed to a transverse shaft operated by a spur wheel, rack, and air piston. The lever is intended to reach well under the bottom of the ship to be attacked. The bottom of the ship is so weak that, according to General Berdan, the gas at once enters the ship without lifting the water at the side, or doing damage to the ram itself. Small boats on the same principle should be employed to protect the ram during its attack from torpedo boats, &c. The inventor supposes that a charge of 20lb. of gun cotton would destroy a torpedo boat or ordinary merchant vessel. The important features of this system are the guards which protect the spurs and propellers; the method of swinging the torpedo in a circle, instead of causing it to run straight on, by means of which the nets may be avoided, and the torpedo applied to the bottom of the ship, where its action is all powerful to damage the enemy, but harmless to the ram; and the positive motion given to the torpedo by means of the lever.

FOREIGN INDUSTRIES.

(From our own Correspondents.)

PARIS, 24TH APRIL, 1888.

THE IRON MARKET.—Notwithstanding the issue of circulars last week announcing to customers an advance in the prices of iron, many of the merchants continue to sell at the former quotations. To bring this state of things to a speedy end the manufacturers of the North have resolved to take the step they have long contemplated, viz., to establish agencies in the capital, through which they will deal directly with consumers. As a measure of this character must lead to the utter destruction of the trade of the merchants, we may expect to see an immediate "face about" on the part of the latter. The reports to hand this week from the principal centres of the iron industry are very encouraging. Despite the uncertainty of the political situation business is reviving everywhere. The resumption of building operations has served as a stimulant to the trade in joists, which is now animated. Bars, too, are in better demand, and prices, outside of Paris, are firm or steadily rising. On the whole the prospect has greatly improved within the last few days.

THE METAL MARKET.—The fluctuations of the market for copper and tin have now no significance from an industrial point of view. Every movement is the result of speculation. This week, on a report of a sudden rise in the United States, copper advanced a few shillings a ton, though genuine business has shrunk to a mere shadow of what it was some months ago, and stocks constantly increase. A slight reaction has shown itself in tin, which may be bought for future delivery at lower prices. Lead is weaker, notwithstanding the higher rates in England, Holland, and Germany. The expected fall in spelter has taken place. Present quotations are 8s. a ton below those of last week, and the tendency is still downward.

THE IMPORT COAL TRADE.—The rapid development of the coal mining industry in the North of France is, in spite of the larger consumption of fuel occasioned by the revival of trade, beginning to tell upon the imports of foreign coal. The total imports of coal in the first quarter of the current year, destined for consumption in the country, amounted to 1,974,715 tons, against 2,035,288 tons in the corresponding period of 1887. The falling off is observable in all directions. Thus the imports from Great Britain were 911,947 tons, against 914,257 tons; those from Belgium were 910,179 tons, against 946,267 tons; those from Germany were 151,672 tons, against 173,365 tons; while from other countries there were but 916 tons, against 1400 tons last year. On the other hand, the imports of coke have increased from 239,862 tons in 1887 to 245,502 tons in 1888. The increase here is wholly in the trade with Belgium, from whence the greater amount of the coke is derived.

THE WINE DUTIES AND FRENCH TRADE.—The proposal of the British Chancellor of the Exchequer to increase the duties on bottled wines imported into the United Kingdom has caused consternation in France, not only among the wine growers and merchants, but also in the glass bottle making industry. The disastrous effect which that measure, if passed into law, must have on French trade has induced the Minister of Commerce to protest against it to the English Foreign Office. M. Lalonde, Deputy for Bordeaux, in bringing the matter to the notice of M. Goblet, pointed out that the proposed duties will be almost prohibitive, and will have two consequences: (1) To greatly lessen the consumption of French wine in England, and (2) to cause the bottling to be done in England instead of in France. The latter consequence will deprive French industry and French workmen of the supply of bottles, corks, and cases requisite, and the labour of bottling and packing. Last year, the quantity of wine exported from France to England amounted to 7,070,162 gallons, of which quantity, nearly half, viz., 3,164,656 gallons, were sent in bottles. The importance of the export wine trade to the glass bottle making industry is seen in the fact that in 1887 the whole of the bottled wine exported from France amounted to 6,803,236 gallons. The quantity of full bottles of all sorts exported from France last year amounted to 988,689cwt. Add to this 319,362cwt. of empty bottles, and we have a total of 1,308,051cwt.—a trade of no mean importance.

BERLIN, 23RD APRIL, 1888.

THE COAL MARKET.—Great activity prevails in the coal market, especially in household coal. There is also a good demand for coal for blast furnace purposes, and for the manufacture of coke. The export trade is in a satisfactory condition, and the reduced rates of freight for the carriage of coal to Italy on the Gothard railway, which have lately come into force, will have a favourable influence upon this branch of trade. In tenders made for the supply of 224,000 tons of coal for the Elberfeld railway, sixteen of the largest collieries quoted 5·80 marks per ton at the pit; one colliery quoted 5·90 marks, and another 5·75 marks. The lowest prices were those of the Neuessen colliery of Essen, and of the Vereinigte Bommerbünker Tiefbau colliery of Bommern, which were 5·45 and 5·40 marks respectively.

THE IRON MARKET.—The crude iron market generally has been rather quieter during the past week, as consumers have bought all they require for the present quarter. The prices obtained were somewhat higher than those paid in the previous three months. The rates for rolled iron continue firm, and an improvement is expected in the trade in girders. Fine sheets are in good demand for roofing purposes, and heavy sheets are also in greater request. The Hörde Company is busy manufacturing armour plates at remunerative rates. The export trade in rolled wire is weak, and the prices obtained do not allow of much profit; but the home rates are considerably better. The demand for wire nails is good, and there is every prospect of its being maintained. Prices are firmer owing to the Saxon works having joined the wire nail syndicate; the Westphalian Wire Company, however, still holds aloof. Waggon works are well supplied with orders, and steel manufacturers who supply wheels and axles will therefore benefit. Engineering works and boiler makers are also busy. The rolling mills in Upper Silesia are well supplied with work, and orders are plentiful for bar iron and iron sheets. The business with Russia is still in an unsatisfactory condition. At a recent contract for the supply of 4000 tons of steel rails for the Erfurt railway, the following tenders were received: The Bochum Union, 116 marks at Bochum; the Aix-la-Chapelle Hüttenactienverein, 114 marks at Rotte Erde; and Messrs. Bolckow, Vaughan, & Co., 116·20 marks free at Stettin.

THE EXCAVATIONS FOR THE NORTH SEA BALTIC SHIP CANAL.—Tenders have been received for the excavation of two portions of the North Sea Baltic Ship Canal. A remarkable feature of this tendering is the wide differences in the estimates. The volume of earth to be removed amounts in one case to 1,488,000 cubic metres, and in the other to 878,000 cubic metres. The lowest of the thirteen tenders received was 9d., and the highest 1s. 3¾d. per metre. The canal commission will take four weeks to consider those tenders. Work has already been commenced on the canal at Brunnsbüttel, and as a part of the soil to be excavated consists of clay, it is intended later on to utilise it for the manufacture of bricks. No barracks have as yet been erected for the workmen; but one of the buildings of the Ducker Portable Barracks Company is to be put up, and if this is found suitable for the purpose, it will probably lead to a good business.

INDUSTRIAL EXHIBITION AT BREMEN.—An industrial exhibition of considerable importance is to be held at Bremen in 1890. Active steps are already being taken to secure the success of the undertaking. This exhibition, which will be open from June to September inclusive, will recommend itself to English manufacturers and export merchants. A committee has been formed, at the head of which is Herr Charles Papendieck, to make and carry out the preliminary arrangements.

LEATHER.—The Berlin leather market has been more active during the past week than for some time past, this being due to large purchases having been made by provincial dealers. There is a good demand for inner sole leather of the cheaper kinds. Cow hides are not in much request, and leathers for uppers is quiet.

TOBACCO.—Some years ago the cultivation of tobacco in the Palatinate was an important industry of this country; but according to recent reports the prices obtainable have sunk so low that the cultivation of the article is almost entirely unremunerative. This is partly due to over production, and it is stated that only the better kinds of tobacco, cultivated under the most improved methods, will in future be able to be produced advantageously.

VIENNA, 23RD APRIL, 1888.

THE COAL MARKET.—There has been greater activity in the coal market during the past week, owing to the continuance of cold weather. A proposal has been laid before the Vienna Town Council to establish a municipal coal depôt in that city. Another suggestion which has been made is for the establishment of a coal consumers' union, which would buy coal in large quantities, and thus be in a position to supply its members at cheap rates.

THE IRON MARKET.—There is not much change to report since my last letter, business being satisfactory in Austria, and decidedly active in Hungary. There is a good demand in Austria for bar iron, constructive iron work, and black plates, and it is expected that there will be a rise in the syndicate price for merchant iron. The crude iron market is firmer, and forge pig has slightly advanced in price. There is at present a very good demand for axes. In Hungary, building iron has been in greater request. Owing to the keen competition amongst middlemen, the prices have slightly fallen, although the works maintain the rates of the syndicate. The balance sheet of the Alpine Mining Company for 1887 shows a great improvement on the previous year.

THE METAL MARKET.—Some spasmodic movements have taken place in the copper market during the past week. These commenced with a series of rises which have, however, not proved permanent, as the rates fell again slowly to the same figure at which they stood last week. There is a better demand for zinc sheets; but tin, lead, and antimony are neglected.

TEXTILES.—The movement in cotton yarns is slow, and prices remain about the same. Owing to the continuance of the cold weather, woollen goods are firm. An improvement has taken place in the demand for mixed cotton and woollen goods. The linen trade is one of the few in Austria of which no complaint can be made regarding want of business, there being at present a strong demand for linen goods.

GOLD MINING.—The prospects of gold mining in Transylvania appear to be very favourable, as at one mine near Brad about £70 worth of gold is being produced daily. American stamps are being used for treating the ore. An English company has commenced operations at Boitza with equally satisfactory results.

RAILWAYS.—The Bulgarian portion of the Oriental Railway will be opened on the 13th of next month, but the Turkish part of the line is not yet completed. The additional facility for communication thus afforded will probably prove of special benefit to Austria, and a commission has been sent by the Austrian Manufacturers' Club to the Balkan districts in order to inquire into the possibility of developing our trade there.

MALT.—As last year's barley harvest in France has been much below the average, and as at the same time the consumption of beer has increased, French brewers had to look abroad for their supplies of malt. Considerable exports of malt have in consequence taken place from Hungary and Moravia to France.

ELECTRIC LIGHTING.—The wiring of the Burg Theatre, which is now being fitted by the Imperial Continental Gas Company, and will be supplied with current from their central station in the Schenkenstrasse, has been officially examined and tested for insulation and conductivity by the president of the Vienna Society of Electricians. He found that the slate basis for cut-outs and other fittings were only poor insulators. Professor von Waldenhofen has just concluded at the Electro-Technical Institute, a comprehensive series of experiments with storage cells of Fahrbaky & Schenek, Reckenzaun, and Julien. The chief object of the experiments was to ascertain the efficiency of each type, especially for tramway purposes, and to eliminate errors in estimating the degree to which the cells had been charged or discharged, the experimenter based his investigation on three measurements—viz., the electromotive force on open circuits, the density of the electrolyte, and the potential difference when at work. The efficiency of the Reckenzaun accumulator was found to be 89·3 per cent. for the quantity, and 80·85 per cent. for the energy. For the Julien accumulator, the figures were respectively 89·7 per cent. and 83·4 per cent.; whilst the Schenek-Fahrbaky accumulator gave 91 per cent. efficiency for quantity and 78·5 per cent. for energy. In connection with the Salzburg central electrical station, a number of electromotors are now in use, the type employed being that of Messrs. Siemens & Halske marked K. This motor is made only for small powers—viz, $\frac{1}{10}$, $\frac{1}{5}$, $\frac{1}{4}$, and 1 h.p., running respectively at 2500, 2200, 1800, and 1200 revolutions per minute. They are used in Salzburg for ventilating and other domestic purposes.

BRUSSELS, 24TH APRIL, 1888.

THE COAL MARKET.—Notwithstanding the approach of spring, the coal market continues active. The recent cold weather has had the effect of clearing the stocks in the hands of dealers, and household coal is still in good demand. Considerable business is being done in coal for industrial purposes. Prices are well maintained, as producers keep firm on account of the contracts which are shortly to be given out by the State railways. Small coal is scarce.

THE IRON MARKET.—The market this week is unchanged, and prices continue firm; but there are signs that the demand will fall off. The scarcity of pig is still making itself felt in the market, and the result is that although at this period of the year a large influx of orders for summer requirements usually takes place, business this year is comparatively quiet. Tenders will shortly be invited for the supply of 18,000 tons of railway material for delivery next year. Tenders will also be invited for the supply of 3000 tons of Goliath steel rails, also for delivery in 1889. The steel market is quiet. Although Government orders for armour plates and other work have given employment to a number of firms, other engineering shops are not very busy, and locomotive builders in particular find business very slack.

ELECTRIC LIGHTING.—The Grand Place has up to now been lighted by two arc lamps of 30 ampères, the motive power being a 12 h.p. steam engine. Two new masts are being erected, each of which will carry two lamps, and the installation will be so arranged that the four new lamps will absorb nearly all the motive power available. The dynamos are compound wound for 70 volts, and the lamps will be coupled parallel, the resistance coils being put inside the foot of the mast. The total expenditure of energy will be 80 ampères at 70 volts.

BRICKS.—From the Liège district numbers of brick makers are leaving for Germany, the demand for labour being good. At Amay alone seven hundred hands have been engaged for Saxony.

THE MEUSE FORTIFICATIONS.—The contracts for these fortifications have at last been given out. They are divided into four parts, of which two include the Liège forts and the other the Namur forts. There will be required for these works 3,300,000 cubic yards of earth work, 1,300,000 cubic yards of concrete work, and 25,000 cubic yards of brick work.

GLASS MANUFACTURE.—The general adoption of the *four-à-bassin* by Belgian manufacturers is causing some stir in France, where it is felt to be necessary to have recourse at once to the same means of cheap production, and where the relative merits of the large and small type are being earnestly discussed. The latter are in use at Marseilles, where they are said to have given excellent results. A new design, just adopted by M. Casimir Lambert, of Charleroi, is much talked about, and commended. This furnace is 8m. broad by 14m. long. The depth of the glass, or "metal" as it is technically termed, in fusion is 1·80m.

Digitized by Google

instead of the usual 1·10m. The mixing chamber into which the gas and air are led has been superseded by a new method of distributing the jets, which is not only more convenient, but saves 25 per cent. of fuel.

DÜSSELDORF, 23rd April, 1888.

The Iron Market.—The iron market is settling down to a state of relative calm. There is, however, a steady and fairly strong current of business, and it is only in relation to the extraordinary activity of the last few months that the market can be described as quiet. The calm is chiefly observable in the business in crude iron. There is nothing being done in spiegel pig on United States account, and forge pig for home consumption is much less actively sought after. For other kinds there is a fairly brisk demand, but the tendency is towards weakness. Prices are, however, firmly maintained, for the situation is favourable to the blast furnace owners, there being practically no stocks in hand. At the end of February the stocks at the thirty works comprised in the Rhenish-Westphalian Pig Iron Association amounted to only 36,341 tons, and this quantity was reduced to 33,582 tons at the end of March—about nine days' production. Moreover, coke prices have still an upward tendency. The markets for finished iron and steel are distinguished by activity in most classes of goods. Bars are in better demand for export, a change in the course of business that has imparted an improved tone to the market. The trade in joists is somewhat wanting in life, but as building operations are more actively prosecuted this market may be expected to revive. Although the Siegen plate manufacturers complain of a scarcity of orders, in this district there is a strong demand for plates. The syndicated works rolled 10,575 tons of plates in March, delivered 10,320 tons, and booked fresh orders for 10,661 tons. Hoops may be bought from 2s. to 3s. a ton below the prices prevailing at the beginning of the month. Manufacturers of boiler plates are now so pressed with work that they are unable to contract for prompt delivery. Business in wire and wire nails is also reviving. Founders and engineers are everywhere busy. The great iron and steel works of Tardy and Bericoh at Savona, in which the Bochum Union holds a third share, has just obtained a contract for 25,000 tons of steel rails for the Italian railways, at the price of £7. 2s. a ton.

Linen Yarn.—The market continues very active for linen yarns. The influence of a steady and strong demand in the presence of constantly diminishing stocks is seen in gradually hardening prices. The demand is partly supplied by increasing imports.

LILLE, 24th April, 1888.

Textile Manufactures.—The disturbing influence of the elections, and the consequent threatening attitude of political affairs, may be clearly traced in the business of the country during the last week. No large transactions have been recorded, nor has any disposition been shown on the part of buyers to push their dealings beyond the needs of the moment. The linen goods trade of this locality has become less animated; but we are now in the dull season, and the calm is in part to be attributed to ordinary influences. The woollen goods trade of the Roubaix district remains quiet, though there is a steady if not strong current of business, and in certain classes of goods the demand is fairly brisk. Our manufacturers have bought largely at the London wool auctions, exhibiting thereby some confidence in the situation. Business at Rouen has revived a little, but the markets are yet far from active. Nothing approaching to animation is to be expected within the next two or three weeks.

Flax and Yarn Markets.—There is but little to be said of the flax market this week. In common with business of all sorts, flax has suffered from the political excitement attending the recent elections. Dealings have been restricted within narrow limits; a small quantity of Walloon has changed hands at former prices, and a few unimportant transactions in Russian have been recorded. The Ghent markets have been equally void of life. Business in yarns has remained active; some large dealings have taken place in linens at full prices. Jute yarns are in good demand. In hemp a larger amount of business has been transacted. The Customs returns for the first quarter of the current year show for that period a degree of activity in the foreign trade which compares favourably with that of the corresponding quarter of 1887. Thus we have as the declared value of the imports: For linen yarns, £82,760 (£58,920); for cotton yarns, £242,720 (£365,920); and for woollen yarns, £133,120 (£112,760), and as the value of the exports of the same classes of goods we have: £65,640 (£64,960); £23,360 (£25,920); and £291,520 (£272,520) respectively. It will be seen from these figures that there has been shrinkage in cotton, and expansion in linen and woollen yarns.

The Iron Market.—Consumers show some hesitation, being apprehensive of disturbing influences arising out of the political situation; but there is no indication of weakness in the market. Two instances have become very clearly apparent, viz., that the manufacturers are firmly banded together to maintain prices; and secondly, that the raw materials of the iron manufacture, ore, coke, and consequently pig iron, are steadily advancing in price. A relapse is thus out of the question, and on the other hand a further advance in finished goods is not to be expected for some weeks to come, for the merchants have in stock, or contracted for, considerable quantities of iron purchased at lower rates than those now ruling

AMSTERDAM, 24th April, 1888

Dutch Commercial Policy.—The new Ministry is the direct result of the recent elections, which were the first held under the reformed Constitution. The Liberals were hopelessly beaten, and the new Cabinet consists of Ministers of a decidedly reactionary character. Protection or "Fair Trade" was one of the platforms upon which the last electoral battle was fought, and the victory of the anti-Liberals means an instant revival of former endeavours to protect inland trades, Dutch industry, and national agriculture, by imposing heavy import duties upon all foreign goods, fabrics, and produce.

Telegraphy in the West Indies.—News has reached the Hague that the English steamer "Roddam" has successfully laid the cable between La Guayra, in Venezuela, and Curaçao. The same telegraph vessel is now engaged in laying the cable from Willemstad to San Domingo, which places Curaçao in direct telegraphic communication with Europe.

WINTERTHUR, 23rd April, 1888.

Electric Lighting.—Progress is being made in various directions in electric lighting. The steamers "Helvetia" and "Thurgau" have been fitted with the electric light, and the North-Eastern Railways intend adopting it for all their steamers on the Lake of Constance. At the Hotel Engadiner Kulm at St. Moritz, 10 arc and about 700 glow lamps are installed. This lighting can be greatly extended, as only half of the water power of 180 h.p. available is at present utilised. A scheme is also on foot for lighting the town of Interlaken electrically, and a commencement will be made by the erection of arc lamps in the Höheweges and the large hotel situated there.

A New Railway on the Righi.—The line between Vitznau and Righi has proved so profitable an undertaking that the Righi is regarded by railway promoters as a most fertile field for their enterprise. In addition to the other line up the mountain on the opposite side, there has now been projected a line from Weggis to Righi Kulm, which will, in the main, follow the old footpath. A concession for this line has recently been asked for, but no particulars regarding the engineering details have yet transpired.

Export Trade.—A company with a capital of £1,000,000, divided into 5000 shares, has been formed at Basle, under the title of Société Générale pour le Développement de l'Industrie Ottomane. Their object is to establish various industrial undertakings in Turkey, and to acquire land, buildings, and machinery for this purpose. It is therefore expected that our export trade will benefit from the purchases of plant which will be required.

MADRID, 23rd April, 1888.

The Agricultural Industry.—Steps are being taken by the Government to establish agricultural schools and laboratories, in order that the methods of cultivating the soil may be improved. The opinion is held by the educated classes that the depression in agriculture is mainly due to want of knowledge. Whether professors who could not manage a farm themselves will be able to teach much is doubtful, but they will probably have an influence in causing the introduction of agricultural machinery and implements. In my opinion, at least one-half of the country can be ploughed by steam, and it will be cultivated in that manner in the course of time.

Manufacture of Dynamos.—The works of Xifra and Co., at Barcelona, which are turning out dynamos of the Gramme type, are conducted on purely co-operative principles. It was established by a society of ten workmen, which now, however, numbers forty. It has proved very successful, mainly owing to the ability of Mr. Xifra, the engineer, whose advice has been of great service to the workmen.

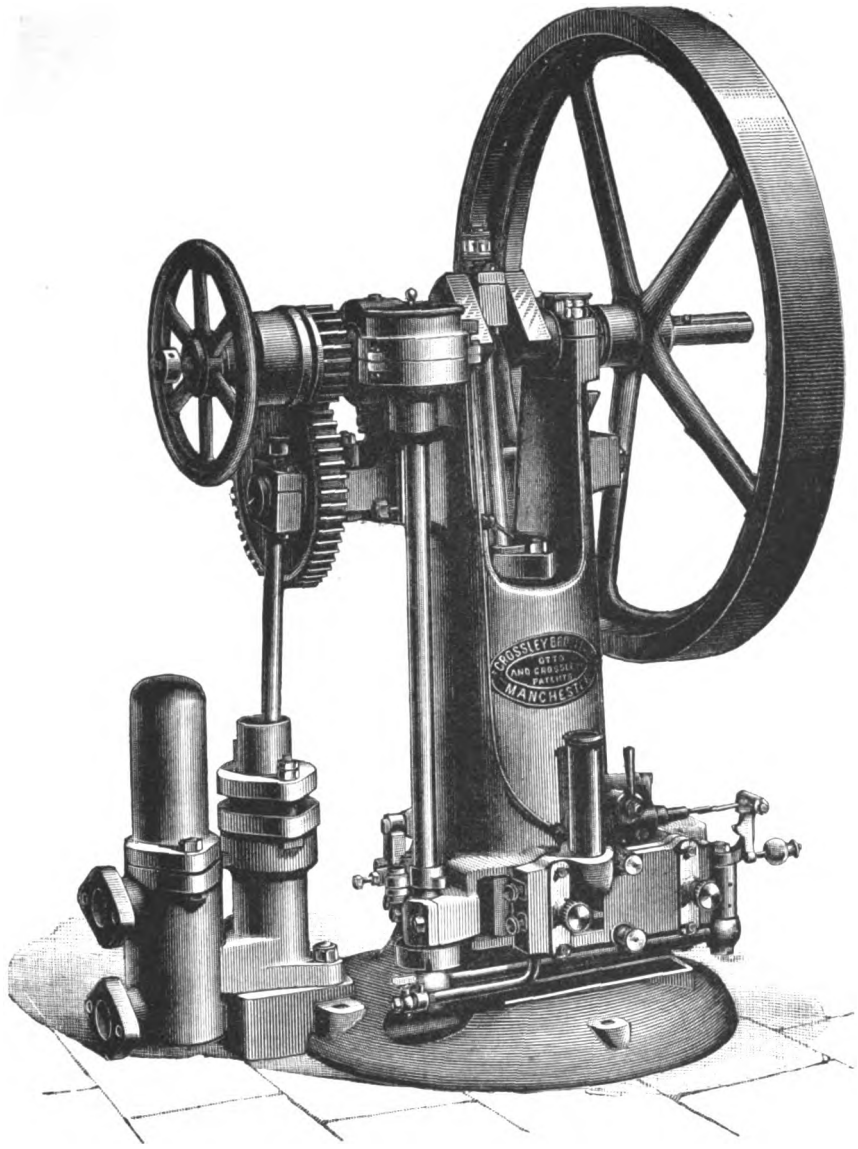
NEW YORK, 14th April, 1888.

The Coal Market.—The anthracite coal trade is dull, and concessions of from 10c. to 15c. a ton are made on circular rates by some of the operators in New York; but the companies are maintaining prices fairly well. The trade has been a good deal disturbed during the week on account of the failure to make any agreement as to the production for the year. The shipments for April will not be over 2,700,000 tons, a decrease of 180,000 tons as against last year. The demand for coal for the Eastern trade is beginning to spring up. The bituminous trade is quiet.

The Iron and Steel Markets.—The volume of business is gradually increasing, but the very bad weather and the agitation on the tariff question have had a tendency to check anything like activity. Besides this, the unusually small amount of work on hand at most of the rolling mills stimulates them to sharp competition for new business, and keeps prices at a point where there is no margin for profit. The present condition of affairs does not furnish any substantial basis for expecting more than a fair average amount of business at a very low range of prices. Some few choice brands still command full prices, but the increasing supply of other brands is beginning to be felt throughout the market. The Thomas Iron Company have made a nominal reduction of $1 per ton on their No. 1 foundry pig. As the Glendon and Andover furnaces are out of blast, besides others which usually supply No. 1 foundry, prices may not yield so readily as they would under other circumstances. There is a considerable accumulation of inferior irons, and this, with the liberal output of the Cornwall furnaces, will furnish ample supplies to the consumers of that class of material. The Lehigh companies estimate that the present cost of making pig iron is $3 greater per ton than it was in 1884. The pig iron producers in Eastern Pennsylvania and the Lehigh Valley are pressing the railroad companies for a reduction in the freight charges on coal, ore, limestone, &c. They take up the position that they can no longer compete with the South and West and pay the heavy charges demanded by the railroads. Some furnaces pay freight on coal at 10c. per ton per mile, while the furnaces on the line of the Pennsylvania Road pay only three-quarters of a cent. The iron masters say that they must have relief or keep their furnaces closed. Business in manufactured iron has been better during the past week, but there has been no improvement in prices. Mill owners are so anxious for work that they are quite willing to duplicate orders taken at the low prices recently prevailing, and the prospects for better rates are not encouraging. Mills are running on an average at perhaps two-thirds of their capacity; but though orders do not extend far ahead, there have been indications during the past few days of a prospect of greater activity during the spring months. The steel trade has been allowed an additional allotment of 200,000 tons, or 1,050,000 tons for the year; and it is stated that the Eastern mills have sold nearly all their share already. They are all tolerably full of work for the next sixty days, and from the number of inquiries in the market it is expected that they will be kept busy all summer. Prices are firm at $31·50 per ton for large lots, to $32 for small ones.

The Metal Markets.—The copper market has been very dull, but prices remain steady. There is some talk of a pool sale to American consumers, and this may be looked forward to as one of the events of the near future. It is once more announced that the Calumet and Hecla mine fire is out, and that the mine will be opened to-morrow, Sunday. The market closed at 15¾c. to 16c. per lb. for present delivery. Tin has been weak, with only a moderate amount of business, prices being 35·50c. to 36·25c. per lb. for spot. Tin plates are dull, and the price is declining. What little business has been done in lead was purely speculative. Domestic was offered at 4·90c. per lb., with no buyers. Spelter is weak and dull, selling at 4·90c. to 5c. per lb. for domestic.

Telegraphing from Trains in Motion.—The practical value of the induction system of train telegraphy, by which messages can be sent from and received by moving trains, was well illustrated on the Lehigh Valley road during the recent great storm. Each of the trains carried a telegraphic outfit and a skilled operator. The wires are set upon poles only 16ft. high, which expose but little surface to the storm, and while the heavily loaded poles carrying the general wires were blown down, stopping the general service, these remained intact, and telegraphic communication was carried on without intermission. The messages are transmitted from the metal roof of the cars to the line, a distance of nearly 10ft., by induction; and when both cars and wires were buried in the drifts, the system was found to work well, the dry snow having apparently no bad effect. Every train was located, and more than two hundred messages were sent back and forth during the three days of the storm, while on all the other roads, as soon as a train passed out of sight, it became lost to the train dispatcher.



PHILADELPHIA, 14th April, 1888.

Sugar.—An estimate of the production of sugar in this country places it at 1,370,000 tons for 1888. Of this amount the refiners not in the Sugar Trust will melt 370,000 tons, or about 27 per cent. of the entire production, leaving the balance of 1,000,000 tons to be turned out by the Trust refineries. Mr. Spreckels has decided to build a new sugar refinery in this city. For this purpose he has purchased a piece of ground which gives him a water frontage of 450ft., and extends back 1500ft., for which he has paid £100,000. The new refinery will have a capacity of 7000 barrels per day, which is 50 per cent. more than is at present produced by the two refineries we have now. Plans are being made for the machinery and buildings, and it is hoped to have the refinery in operation in a year.

Steel Pipes.—The Riverside Iron Works, of Wheeling, West Virginia, have been engaged in the manufacture of steel pipes since August last. These pipes have been introduced to take the place of iron pipes, and are now announced to be a commercial success. Test pieces were cut from both iron and steel pipe and hung in dilute nitric acid. In twenty-four hours the iron had lost 3·6 grains, while the steel had lost but 1·15 grains, and after forty-eight hours the losses were 6·53 and 2·21 grains respectively. When the edges of the test pieces were protected, of course the loss was much less, but still largely in favour of the steel. Test pieces were taken from machine welded tubes, cut to contain the weld, and on being broken in the tensile machine the steel broke at 52,000 and 66,000lb., and gave 18·75 and 17·25 per cent. elongation in 8in., while the iron broke at 42,480 and 35,240lb., with 2·25 and 0·5 per cent. elongation. None of these pieces broke in the weld. Tests were also made of pieces taken from hand welded tubes, and, while they all broke in the weld, the steel tubes proved to be better

COMBINED GAS ENGINE AND PUMP.

COMBINED GAS ENGINE AND PUMP.

We illustrate above a very neat form of combined vertical gas engine and pump, which has recently been put on the market by Messrs. Crossley Brothers, Limited, Openshaw, Manchester. This convenient and compact combination is made in various sizes, from 5 man to 5 horse power, and will no doubt be found specially useful for domestic installations. The engine can be used for driving a small dynamo or other machinery when not required for pumping purposes, by simply disconnecting the pump from the engine by means of a clutch operated by a hand wheel shown on the left of the illustration. It will be seen that on the fly wheel end of the crank shaft there is room left to fix a pulley for the driving of general machinery. The design of the engine is extremely good, and the whole of the details have evidently been well thought out, with the view of making the combination both simple and effective.

INSTRUCTION IN ELEMENTARY SCHOOLS.

There has been so much said and written on the subject of technical education during the past few years, that people are apt to overlook what should be the foundation of all education, viz., that obtained in the elementary school. Members of School Boards, and a certain class of educationalists, are apt to dwell too much on the statistics of education; but they fail to inquire if what the scholars obtain is education in the proper sense of the term. They point to the fine new schools which have been built, the number of scholars attending them, the passes they make and the grants they earn, and they are satisfied. It never occurs to them that we may have all these, and yet that education may be going backwards. The report which was recently issued by a special committee of the London School Board "to consider the present subjects and modes of instruction in the Board's schools, and to report whether such changes can be made as shall secure that children leaving school shall be more fitted than they are now to perform the duties and work of life before them," must have given a rude shock to the statistical educationalists on the Board, as some of the opinions therein expressed are very strong indeed. For instance, the Rev. J. E. Symns states, that after examining the picked boys from the elementary schools of London his conclusion is, that *the boys are machines*, and he considers the present system of teaching in elementary schools a very poor foundation on which to construct a satisfactory education.

It is quite evident that the special committee have considerable sympathy with some of the severe criticism which is offered on the present system, and they advise that very considerable modifications be made. They find it necessary to define the object of all education as the "harmonious development of all the faculties, bodily and mental, with which the child is endowed by nature," and they state their belief that a great part of the benefits of education are moral benefits, and that "fearless truth, bravery, honour, activity, manly skill, temperance, hardihood, welded into a great national character," are objects of national education. "Noble character comes first, the training of skill and strength comes next." When they inquire if the present system does produce such harmonious development of all the children's faculties, bodily and mental—that they leave school fitted, as far as possible, for the battle of life, they find there is an almost universal consensus of opinion in the negative on the part of the witnesses of all classes. The evidence shows in the first place that the physical or bodily side of education, including the development of muscular strength, of the accuracy and the sense of colour and of proportion, and of the pliancy and dexterity of the hand, is almost entirely neglected; and that in the second place, the mental or brain work, which occupies the great part of the time in schools of all kinds, is composed far too much of appeals to the memory only, resulting at the best in the retention in the child's mind of a mass of undigested facts, and far too little of the cultivation of intelligence. The committee quote with approval the opinion of Professor Huxley, that elementary education is "too bookish, too little practical. The child is brought too little into contact with actual facts and things, and there is no education of those particular faculties which are of the utmost importance to industrial life—the faculty of accurate work, and the faculty of dealing with things instead of words." They point out that the results are such as might have been expected. There is not in the curriculum anything which ennobles labour, and the boys are given an undue bent towards clerkly and non-manual pursuits. On the other hand, children are not prepared when they leave the elementary school to profit by the training given in secondary and technical schools, and are often discouraged from taking the first steps in an industrial career.

The special committee believe that it is possible to improve the school curriculum by bringing manual work to the aid of the intellectual, and thus throw life into the formal and parrot-like instruction which now leaves so little impress on the children's minds; and they remark that it is significant that these changes are demanded alike by educational theorists, teachers, men of science, leaders of industry, and statesmen, and it rests with the Board to carry them out. The committee point out that the problem before the Board may be regarded as divided into the following heads, to each of which they give special consideration: (1) Just balancing of the claims of mental and manual work in an elementary school; (2) gradual specialisation of school work, so as to meet the separate needs of the various classes of children; (3) relation of elementary education to continuation and technical schools; (4) teaching power; (5) school buildings; (6) cost; (7) powers allowed by the code of the Education Department. Each of those topics is very fully discussed; but for details we must refer to the report, as our space will only allow us to notice a few of the more important points. The committee recommend that arrangements be made for the more thorough teaching of science in the higher classes by means of the peripatetic system, until at least there are ordinary teachers in all the schools capable of giving efficient instruction in science subjects, and they further recommend that special manual instruction should be given under the following principles: (1) That manual work should always be taken in connection with school teaching of underlying sciences and of drawing; (2) that no special trade be taught. They are of opinion that teachers and managers should have liberty in making experiments in methods of giving this teaching, as there is not sufficient experience of it in England to enable an opinion to be given regarding the adoption of any general system, even if that course were desirable. They think, however, that wood work supplies the most convenient mode of giving manual instruction to older boys. The material is cheap and easy of manipulation, and can be made illustrative of the intellectual work of the school. The tools used are simple. The articles made should illustrate educational principles, and in no case should the school be turned into a manufactory of saleable articles. The making of mechanical models and apparatus of various kinds necessary for explaining science teaching would stimulate the boys' intelligence. The committee do not recommend the use of the lathe in the work room. The evidence given before the committee shows that artisan class objections to manual training in elementary schools disappear when it is known that the object is entirely to improve general education, and no attempt is made to teach any trade, or to turn out boys who can fancy that they are skilled workmen. Special recommendations are made for the teaching of cookery, needlework, and knitting to girls, and suggestions are given for the improvement of the ordinary branches of an English education, and for drill and physical exercises. Specialisation of school instruction to meet future circumstances can only exist outside the elementary subjects, and as the majority of children require to leave Board schools before they are able to get much beyond the general elements of education, they can only proceed with their industrial, commercial, or literary education in evening classes or continuation schools; and to these special attention should be given. The committee think that wide power should be granted to the Board in organising the curriculum of its classes, so as best to meet the wants of scholars; and that the grants, whether of the Education Department or the Science and Art Department, should be given for efficient and complete class teaching rather than for the individual examination of the evening scholars. Also with regard to science and manual teaching, the committee think it is desirable that individual examination in writing should be applied as little as possible, and that in manual instruction a Government grant similar to that for cookery should be given, where payment is made for qualified instruction and regular attendance.

The evidence printed along with the report should be carefully studied by all interested in education; for as the committee remark, they cannot exaggerate the importance of the question with which they deal. It vitally affects the future of the mass of London people. "Everybody suffers when education goes wrong. The failures are the lives of men. The teacher's workshop is strewed, not with shavings and wasted wood, but with wasted years and broken lives."

SHIPBUILDING NOTES.

Messrs. Dobson & Co., Newcastle, launched on 12th inst., a vessel named "Ben More," built to the order of the Grampian Steam Shipping Company, Dundee. The vessel is 255ft. long by 34ft. 6in. wide, and 17ft. 6in. deep, and will be fit to take about 2500 tons of cargo. The engines are by the North-Eastern Engineering Company, Wallsend.

Messrs. Readhead, South Shields, launched on 12th inst. a vessel named the "Harperly," built to the order of Mr. William Wright, South Shields and London. The vessel, which is 300ft. long by 29ft. wide and 20ft. deep, has a dead weight carrying capacity of 3350 tons. The engines will also be supplied by Messrs. Readhead.

Messrs. Brown & Co., Newcastle, launched on 12th inst., a wooden screw steamer, intended for the coasting trade. The vessel is 90ft. long by 20ft. wide, and 9ft. deep. She is specially constructed for light draught, so as to be able to enter rivers and harbours where the depth of water is insufficient for the safe navigation of larger vessels.

On the 13th inst. the oil-in-bulk steel steamer "Caucase," built by Messrs. Armstrong, Mitchell, & Co., Limited, at their Walker-on-Tyne shipbuilding yard, proceeded on trial, loaded to her ordinary draught of water, with 2400 tons of water. The vessel is constructed on Swan's patent, and with the usual good workmanship necessary for this class of craft. The engines and boilers have been supplied by the Wallsend Slipway and Engineering Company, Limited.

On the 13th inst. Messrs. W. Gray & Co., West Hartlepool, launched the steel screw steamer "Lowlands," built to the order of Messrs. Hardy, Wilson, & Co., West Hartlepool. Her principal dimensions are: Length over all, 270ft.; breadth, 36ft. 6in.; depth, 19ft. 5in., having 2500 tons dead weight capacity. The engines—triple expansion—19in., 30½in., and 51in. diam. of cylinders, 36in. length of stroke, to indicate 700 h.p.; the two steel boilers of 150lb. working pressure have been constructed by the Central Marine Engineering Company, Limited, West Hartlepool.

Messrs. Wm. Hamilton & Co., Port Glasgow, launched on Saturday, the 14th inst., the steel twin screw steamer "Macassa." The vessel, whose dimensions are 166ft. by 24ft. by 16ft. 3in., moulded depth, is of 459 tons gross, and is intended for passenger service on Lake Ontario. The engines, 750 i.h.p., have been built by Mr. Kemp, Govan. The "Macassa" is luxuriously furnished for a high class passenger traffic, and is fitted throughout with electric light.

On the 14th inst. the steel screw steamer "Ben Clune"—the eleventh vessel built to the order of Messrs. J. Morrison & Sons, North Shields, by Mr. James Laing, Deptford Shipbuilding Yard, Sunderland—proceeded on her trial trip, fully loaded with 2850 tons dead weight at 19ft. 6in. draught of water. The vessel's registered dimensions are: Length, 273·5ft.; breadth, 38·25ft.; depth of hold, 19·35ft. The engines are of the triple expansion type, with cylinders 21in., 33in., and 54in. diam., and 39in. stroke. The steel boilers, of 150lb. working pressure, have been constructed by Mr. George Clark, Southwick Engine Works, Sunderland. The vessel had a trial trip extending over several hours, and ran the measured mile at Whitley at progressive speeds, the engines working satisfactorily. The maximum speed was 10 knots against wind and tide, and 11½ knots with wind and tide, or a mean of 10¾ knots per hour.

Cleveland Institution of Engineers.—The fourth meeting of the session was held in the Society's Lecture Hall, on the 16th inst., Mr. Richard Howson, president, being in the chair. After some preliminary business, Mr. D. D. Wilson, general manager of the Stockton and Middlesbrough Corporations' Water Board, read an exhaustive paper on the undertakings of the Water Board, being chiefly historical, financial, and statistical, leaving the engineering subjects to be hereafter dealt with in a paper which Mr. Mansergh, C.E., has promised to furnish. Mr. Wilson traced the history of the water supply to the towns of Stockton and Middlesbrough from the time when the source of supply was a few pumps and wells, supplemented by the storage of rain water in tubs and the river Tees, down to the present time, when a splendid supply is obtained from the several large reservoirs in the upper reaches of the Tees. He also explained the progress of the works in connection with the further supply from the Hury reservoir. A vote of thanks to Mr. Wilson brought the meeting to a close, the discussion having been postponed till next meeting.

We have just received a new catalogue and price list from Messrs. Crossley Brothers, Limited, Openshaw, Manchester, which contains a number of new and neat designs of gas engines, and combinations of gas engines, with other machines. One of the most noteworthy features of this catalogue, are the excellent illustrations throughout the work. The first part is occupied with illustrations of gas engines; the second part contains different combinations of gas engines and machines, and in the end pages is given a short description of the Dowson gas plant used in connection with Messrs. Crossley's engines. In the early pages is shown a small domestic motor capable of indicating up to ¾ h.p., and a new design of a 20 n.h.p. horizontal "Otto" gas engine, which we understand is now largely used. Further on are shown two designs of combined gas engine and dynamo, a combined gas engine and pump, which we illustrate on page 422 in the present issue, and a gas engine combined with a dry air refrigerator. The artistic appearance of this catalogue, and the several novelties contained in it, make it well worthy of attention.

Notices of Meetings.

THIS WEEK.

Royal United Service Institution.—Friday, 27th April, 3 p.m. Paper to be read on "The Mechanism of the Counter Attack," by Major W. W. M. Smith.

Physical Society.—Saturday, 28th April, 3 p.m. Papers to be read on "Electromotive Force by Contact," by Mr. C. V. Burton; on "A Theory concerning the Sudden Loss of Magnetic Properties of Iron and Nickel," by Mr. H. Tomlinson; and "Note on the Graphic Treatment of the Lamont Frölich Formula for Induced Magnetism," "Note on the Conditions of Self Excitement of a Dynamo Machine," and "Note on the Conditions of Self Regulation in a Constant Potential Dynamo Machine," by Professor S. P. Thompson.

NEXT WEEK.

Society of Arts.—Monday, 30th April, 8 p.m. Cantor lecture on "Decoration," by Mr. G. Aitchison, A.R.A.—Wednesday, 2nd May, 8 p.m. Ordinary meeting. Paper to be read on "Drawing, a Means of Education," by Mr. T. R. Ablett.—Friday, 4th May, 8 p.m. Indian Section. Paper to be read on "The Injurious Effects of Canal Irrigation on the Health of the Population of the Punjab," by Surgeon-General H. W. Bellew, C.S.I.

Institution of Civil Engineers.—Tuesday, 1st May, 8 p.m. Ordinary meeting. Paper to be further discussed, on "The Distribution of Hydraulic Power in London," by Mr. E. B. Ellington, M.Inst.C.E.

Royal Institution of Great Britain.—Tuesday, 1st May, 1-30 p.m. Annual meeting, Tuesday, 1st May, 3 p.m. Lecture on "The Plant in the War of Nature," by Mr. W. Gardiner. Thursday, 3rd May, 9 p.m. Lecture on "The Chemical Arts," by Professor Dewar.

Chemical Society.—Thursday, 3rd May, 8 p.m. Papers to be read on "The Determination of the Molecular Weights of the Carbohydrates," by Mr. Horace T. Brown and G. H. Morris, Ph.D.; on "The action of Heat on the Salts of Tetramethylammonium," by Mr. N. Collie and Dr. Lawson; and on "The action of Heat on the Salts of Tetramethylphosphonium," by Mr. N. Collie.

Institution of Mechanical Engineers.—Thursday, 3rd May, 7-30 p.m., and Friday, 4th May, 2-30 p.m. Ordinary general meeting. Papers to be read: "Third Report of the Research Committee on Friction: Experiments on the Friction of a Collar Bearing;" "Description of the Emery Testing Machine," by Mr. Henry R. Towne; and "Supplementary Paper on the use of Petroleum Refuse as Fuel in Locomotive Engines," by Mr. Thomas Urquhart.

Architectural Association.—Friday, 4th May, 7-30 p.m. Ordinary meeting. Nomination of officers. Paper to be read by Mr. H. H. Statham.

Geological Association.—Friday, 4th May, 8 p.m. Ordinary meeting.

Junior Engineering Society.—Friday, 4th May, 7-45 p.m. Paper to be read on "The Elements of Stresses in Structures, illustrated by Models and Diagrams," by Mr. W. Quick, C.E.

PRICES CURRENT, 26th April.

Quotations at per ton, unless otherwise specified.

" Australian	167	0	0	"	——		
" English Ingots	140	0	0	"	145	0	0

Messrs. Carrick & Brockbank, Manchester, report as follows:—

Copper.—Quotations for Chili cash parcels are practically unaltered, £80. 5s. to £80. 10s. per ton; three months £77. 5s. to £77. 7s. 6d. Manufactured continues inactive, and this influences the market for raw copper adversely, so that the quotations for three months later delivery are gradually falling.

Tin.—Irregular. Spot parcels of Straits are still quoted £166 per ton, for deliveries a week hence £128 per ton, and for three months down to £110 per ton. English is lower. The prices are thus giving way very rapidly, because of the great increase of stocks.

Lead quiet. Quotations for Spanish rather better, £13. 17s. 6d. to £14 per ton.

Spelter steady at about £17. 10s. per ton for warrants. The present price being so much lower than it was a few months ago, is attracting buyers, and a large business is doing in this metal.

CARRON PIG IRON—BRAND "CARRON."

We have just received the catalogue and price list of the Brown & Sharpe Manufacturing Company, and of Messrs. Darling, Brown, & Sharpe, both of Providence, Rhode Island, United States. The first part of the catalogue contains prices and illustrations of machinery, tools, and castings, including milling machines, cutters, and gear wheels, made by the Brown & Sharpe Company; while the second part is occupied by a selection from Messrs. Darling, Brown, & Sharpe's measuring instruments, comprising United States standard rules, cast steel squares, standard wire gauges, and instruments for accurate measurements, of which numerous illustrations are given.

HOME INDUSTRIES.

MANCHESTER, 26TH APRIL, 1888.

THE COTTON TRADE.—The condition of business does not show any material change since our last report. On the whole spinners have plenty of work, and in some cases are under contract for some months ahead. There is a little abatement of prices for new orders, but the reduction is much more than covered by the lower price of cotton. A profitable margin exists in all departments of the trade, but it is not so large as to cause any feeling beyond satisfaction. The wants of spinners are covered, and the weekly average of the sales during this season is about 75,000 bales. This would indicate a large increase in the amount of yarn spun, and this increase continues in spite of the small number of mills being built, and, no doubt, arises from the gradual improvement of the speed of the machinery employed. Unless better counsels prevail, the spinning trade will be disturbed in the course of a month by an extensive strike. The conference to which we referred last week not having resulted in any agreement between the two parties, the operatives have given notice of their intention to strike, if an advance of 5 per cent. on spinners' wages and of 10 per cent. on those of card room hands, is not conceded. These notices expire on the 21st May, and although at present the formal notice has only been given in Oldham and Blackburn, the dispute practically affects a very much wider area. It is to be hoped that before the time for the expiration of the notices a more reasonable spirit will prevail. In the cloth market there is little animation, and where contracts are expiring, fresh ones can only be had at a reduction on the old rates. There is abundant evidence that there is sufficient productive power for the existing demand, and that the additions which are being made are likely to have the effect of bringing quotations down to an unprofitable figure. Unless there is a considerable increase in the demand, there will shortly be several stoppages of looms owing to shortness of work. The Union Manufacturing Company, Limited, of Rochdale, have placed an order for 1350 looms for their new shed with Mr. George Keighley, of Burnley. It is the intention of the directors of this concern to manufacture the better classes of cloth, rather than compete in ordinary grey cloths. There is an agitation going on in the Blackburn district among the drawers and twisters, for an equalisation of their wages list.

NEW WORKS.—The Roburite Explosives Company, Limited, of which Sir John Stokes is chairman, are rapidly completing their new works at Gathurst, near Wigan, the site of which covers thirty-eight acres. It is expected that the manufacture of the new explosive will begin early in May, and we understand that there are a large number of orders already on the books. The peculiarity of this explosive is that it does not explode by fire contact, but only by detonation, and it is intended to supply it in the form of two powders, which can be mixed together when required for use, both being harmless when separate. The works are accordingly laid out in two departments, connected by tramways.

THE IRON TRADE.—There is only a very small demand for pig iron in this market, and the continual weakening of prices prevents buyers from purchasing. There is always a steady flow of orders, but there is no inclination to do more than buy for present requirements. The market therefore is very lifeless, and as makers do not yield to any large extent, most of the transactions are passing through the hands of merchants. Bar iron is only in slow request, and prices are nominally about £5 per ton for common qualities of bars. Except for a few special purposes in connection with cotton machinery, the use of marked irons is becoming very small, and the price of these is closely approximating to common grades. A rather large parcel of this quality has been recently placed at £5. 5s. per ton delivered in North-East Lancashire, less 2½ per cent. The use of steel is on the increase, and several large sheds are being fitted with steel shafting. In machine making establishments, however, where every turner is paid by piece work, the extra time consumed in turning steel makes the cost of production too great, and, in consequence, best turning iron is still largely used. It is reported by many makers of machinery that rollers made of steel do not wear so long as those made from best iron, as they grind away in the necks. This is worth the attention of steel makers, as if the two defects named could be overcome, a largely increased use of steel would follow.

LONDON, 26TH APRIL, 1888.

THE MONEY MARKET.—After a quiet week, in which the absence of demand was denoted by rates gradually going lower and lower, the money market has strengthened a little on account of the Stock Exchange settlement, which has occupied the past three days; but the improved demand is only temporary, of course, and there is still a prospect of a continuance of cheap money. The settlement has rather checked business on the Stock Exchange this week, but the tendency of the markets is all in the direction of improvement. Continental news having been more reassuring, the markets have been firmer. All foreign stocks have participated in the upward movement, Egyptian securities, in spite of the rumours about the possible conversion of the Five per Cent. Preference Loan, having gained in price. The British funds are better than they have been for a fortnight. Home railways show no inclination to mend in price, and will not do so until the weather becomes a little more seasonable. As regards American railways, Wall-street and Capel Court, after waiting on one another for a long time, have concluded to go hand in hand in the right direction, and the prices of the more substantial securities have gained several points. Were it not that such a movement in Americans is nearly always followed by a pause, this market would offer at present a good opening for speculative investment.

COMPANIES.—The number of new companies registered lately has been quite abnormal, on account of the proposals of the Chancellor of the Exchequer. The following among others have been registered since our last report: The Gatling Gun Company, Limited, with a capital of £800,000; Turney Brothers, Limited, with a capital of £120,000, to purchase a leather manufacturing business at Nottingham; Alton and Co., Limited, with a capital of £110,000, to acquire the business carried on at Wardwick Brewery, Derby; Ashby's Cobham Brewery Company, Limited, with a capital of £48,000; Southampton Electric Light and Power Company, Limited, with a capital of £30,000; the Town Hall Brewery (Salford), Limited, with a capital of £20,000; the Low Moor Iron Company, Limited, with a capital of £300,000; Schmidt Brothers, Limited, with a capital of £75,000, to manufacture steel fencing wire, &c.; the Hull Portland Cement Company, with a capital of £10,000; Fenner & Co., Limited, with a capital of £60,000, to deal in and manufacture oils; South American Petroleum Company, Limited, with a capital of £501,000, to sink petroleum wells in Peru; Kerosene Company, Limited, with a capital of £300,000, to trade in and manufacture oils; Central Quartz Milling Company, Limited, with a capital of £150,000, to carry on the business of crushing quartz in the Transvaal or elsewhere; Dorado Railway Company, Limited, with a capital of £172,000, to acquire a concession for a railway in the Republic of Colombia; Hutchinson Petroleum Motors, Limited, with a capital of £60,000; New Organos Gold Mining Company, Limited (South America), with a capital of £75,000; the New Astor Mine Company, Limited (Colorado), with a capital of £250,000; Cerro Blanco Mines, Limited (Mexico), with a capital of £150,000; New Gold Hill Company, Limited (North Carolina), with a capital of £350,000; New Akankoo (Gold Coast) Mining Company, Limited, with a capital of £150,000; Pioche Mining Company, Limited, with a capital of £250,000; the New Flagstaff Mining Company, Limited, (Utah Territory), with a capital of £300,000; Mapoota Land Syndicate, Limited, with a capital of £50,000, to acquire mining rights in South Africa; Montrose Gold Mining and Exploration Company, Limited (Africa), with a capital of £70,000; the Hungarian Bonanza Mines, Limited, with a capital of £20,000; Golden Gate Alluvial Syndicate, Limited (U.S.A.), with a capital of £50,000; Santa Catalina Gold and Silver Mining Company, Limited (Arizona Territory), with a capital of £225,000; the Kaiser Gold Mines, Limited (Arizona), with a capital of £200,000; and the Madras Presidency Diamond Fields, Limited, with a capital of £190,000.

SHIPPING.—Very little change has taken place in freights, but those to and from the Black Sea have improved to some extent. Though the rates from India to England are poor, the outward freights are sufficiently high to make a return voyage profitable. American freights continue to be unsatisfactory.

HEMP.—Although the state of business at present does not compare very favourably with the position at the commencement of March, affairs are nevertheless on a sound basis. There is no change in the prices of Baltic hemp and yarns. Business in Manilla hemp has been very moderate.

THE NAVY.—The tender of Messrs. Humphrys, Tennant, and Co., of Deptford, for the engines and the torpedo depôt ship to be built at Portsmouth, has been accepted by the Admiralty. The engines are to indicate 12,000 h.p. A number of shipwrights have been discharged at Devonport Dockyard. At Portsmouth material has been received for the construction of the "Beagle" and the "Barossa;" the former is a sloop of the B type, and the latter a protected cruiser of the third class. The "Nymphe," which was laid down at Portsmouth in June last, is to be floated out of dock on the 1st of May. She is a twin screw, wooden sheathed sloop of 1140 tons displacement. The work of repairing the old "Victory," which had been temporarily suspended, has been resumed, and is likely to last for three months. The total cost will be about £10,000. The "Sans Pareil," which is being built by the Thames Iron Works Company, is to be completed for sea at Portsmouth, and not at Chatham, as was originally intended. We have received from the secretaries of the bazaar, a very neat hand book of the Royal Naval and Military Bazaar to be held at the Hotel Metropole next month.

RAILWAYS.—The gross receipts of the twenty-three principal railways in the United Kingdom for the week ending 15th April amounted to £1,189,237 on 15,850¾ miles, as compared with £1,221,156 in the corresponding period of 1887, when the mileage was 15,708¾ miles. An increase is thus shown in the mileage of 142 miles or 0·9 per cent., and a decrease in the receipts of £31,919 or 2·6 per cent.

THE WRITING TELEGRAPH.—In *Industries*, Vol. III., page 259, we gave a description of a writing telegraph invented by Mr. J. H. Robertson, which was exhibited at the American Exhibition. The Post Office authorities now state that they decline to grant a license for the use of the writing telegraph, and think it preferable that if there is a substantial demand for the establishment of exchanges to be worked by that instrument, they should be in the hands of the Post Office, and that the system should not be worked as telephone exchanges are at present.

IRON AND STEEL INSTITUTE.—The annual meeting of the Institute is arranged to be held on the 9th and 10th prox., at the hall of the Institute of Civil Engineers, 25, Great George-street, Westminster. Business will commence each day at 10-30 a.m., and will be resumed on Friday, the 11th prox., if necessary. The following papers will be read as far as time will permit. Adjourned papers: (1) "On the Mutual Action of Sulphur and Silicon in Iron at High Temperatures," by Mr. T. Turner, Mason College, Birmingham; (2) "On the Use of Water Gas for Metallurgical Purposes," by Mr. A. Wilson, Stafford; (3) "On an Imperfection in Mild Steel Plates, considered Chemically," by Mr. H. Eccles, Port Talbot; (4) "On the Mechanical Apparatus for Continuous Moulding at the Works of M. Godin, Guise," by Mr. Jas. Johnston, Manchester; (5) "On the Effect of Arsenic on Mild Steel," by Mr. F. W. Harbord and Mr. A. E. Tucker, Bilston; (6) "On the Manufacture of Ordnance at Trubia;" by Major Cubillo, Trubia. New papers: (7) "On the Melting of Wrought Iron or Steel Scrap mixed with Ferro-Silicon in Cupola Furnaces," by M. F. Gautier, Paris; (8) "On the Behaviour of Arsenic in Ores and Metals during Smelting and Purification Processes," by Mr. John Pattinson, Newcastle-on-Tyne, and Mr. J. E. Stead, Middlesbrough; (9) "On a New Instrument for the Measurement of Colour, more especially as applied to the Estimation of Carbon in Steel," by Mr. H. Le Neve Foster, West Hartlepool.

EXHIBITIONS.—Rapid progress is being made in alterations and re-decoration in connection with the forthcoming Italian Exhibition, which promises to be very successful. It is intended to open the exhibition about the 12th of May. The Anglo-Danish Exhibition will be opened at South Kensington on the 14th of May.

GLASGOW, 26TH APRIL, 1888.

GENERAL BUSINESS.—A slight accession of business was observable in the operations on the Stock Exchange in the beginning of the week. Quotations, especially in the more speculative stocks, were higher, and there was less disposition to sell for a fall than there has been of late. The iron market is steady but inactive. Shipments are still fairly well maintained. Coal shipments still continue to show a large increase over those of 1887, the shipments to date being about 50 per cent. in excess of those for the corresponding period last year. The freight market is thus fairly active, and outward freights are taken at full rates. Demand for steel continues to keep the steel makers busy, and several very large contracts are now in the market. Among these are a contract for 8000 tons of rails for the Danish State Railways, and one for a railway in Egypt.

SULPHATE OF AMMONIA.—Messrs. Wm. Dixon, Limited, have resolved to manufacture sulphate of ammonia as a by-product at their Govan Iron Works. This has long been done at the works of Messrs. Baird and of the Summerlee Iron Company at Coatbridge, but Messrs. Dixon have not hitherto attempted it. The price of sulphate of ammonia may not improbably suffer from the considerable addition to the supply which this will involve.

THE LIFE SAVING APPLIANCES BILL.—The Clyde shipowners held a conference in Glasgow, on Monday, for the purpose of considering the bearing of the provisions of the bill upon their interests. They ultimately decided to ask Lord Ravensworth to move a series of amendments. These proposed amendments refer chiefly to the constitution and to the duties of the committee. The proposal is that a committee be appointed for the purposes of the Act, and that this committee should consist of the President and three members of the Board of Trade, the President of the Chamber of Shipping, one member of Lloyd's Committee, three members jointly representing the Institution of Naval Architects and the two Institutions of Engineers and Shipbuilders in Newcastle and Glasgow; two practical seamen representing seamen's societies, and eight members representing the shipping interest chosen by the owners in the chief shipowning districts, each owner having a vote for every hundred tons of shipping owned by him. The duties of this committee, as laid down in the proposed amendment, would be to make and vary rules with reference to the subjects covered by the Act, to act as advisers of the Board of Trade in the administration of the Act, and to form a Court of Appeal between the officers of the Board of Trade and any shipowner.

FIRE IN MESSRS. DENNY'S YARD.—The saw mill at Messrs. Denny's yard at Dumbarton was completely gutted by fire on Monday afternoon. The whole of the machinery was rendered practically useless, the loss amounting to upwards of £4,000. As the firm are at present very busy, the occurrence of the fire is a serious inconvenience. The fire is attributed to the heating of the journals of the main shafting.

GLASGOW EXHIBITION.—The boilers and connections being now practically finished, steam was got up in the beginning of the week, and the dynamo machinery put in motion for the purpose of trying the electric light. This was done in some of the courts on Monday evening with success. The mechanical section, now rapidly getting into order, contains many very important exhibits, and altogether the Exhibition compares very favourably with any of the provincial exhibitions, and by common consent excels them all in advantage of situation.

(From our own Correspondents.)

LIVERPOOL, 25th April, 1888.

Sale of the Liverpool Exhibition Buildings.—The whole of the constructional iron work and wood work forming the buildings of the late exhibition, was sold by public auction last week, on the site. The buildings were divided into different sections, and sold in separate lots; the total amount realised by the three days' sale was about £10,000. Purchasers were present from all parts of the country, and in many cases fairly good prices were obtained for the material. Although the total amount realised was considered satisfactory, it is much below the estimated amount published in a former statement of the committee. The full sized model of Eddystone Lighthouse was sold previously by tender for £235 as it stands, exclusive of all machinery.

Enormous Emigration from Liverpool.—The great increase in the emigration from this port which was noted last week has since been greatly exceeded, for last week over 14,000 emigrants sailed for the United States and Canada. Great pressure has been put upon the different Atlantic lines, and they have been compelled to run extra boats to meet the traffic; twelve boats sailed last week fully loaded.

SHEFFIELD, 25th April, 1888.

The Heavy Industries.—The call for pig iron is extensive, and the trade is steady. Customers are buying for present wants, and obtaining slightly easier rates. There is a great demand for steel, and the Bessemer makers are very busy. There is little change to note in the price of billets, except that quotations are a little firmer for best quality. Though the promise of reviving trade has scarcely been borne out this month, still the heavy industries are on the whole in a satisfactory state of activity. The crucible steel makers have good orders on hand, and this fact is indicative of profitable business in the best steel Sheffield can produce. At the works of Messrs. W. Jessop & Sons much heavy material is being turned out, and this firm is steadily developing its trade in castings. Most of the well known Brightside firms are tolerably employed on ordinary material, and Brown's, Cammell's, Firth's, Vickers', Spear and Jackson's, and Jowitt's are doing well in most of their departments; but there is just a slight feeling of soreness among some of these Sheffield firms about the conduct of the War Department. Messrs. Charles Cammell & Co., and one or two other concerns, have put down the most modern plant for the manufacture of heavy ordnance, partly on the understanding that Government orders would pour in. But the orders do not come, and it is whispered that the Government still contemplate, on economical grounds, the manufacture of this heavy ordnance themselves. It is doubtful, however, whether the Government can produce the material so cheaply as these Sheffield firms or Messrs. Whitworth.

Hadfields' Steel Foundry Company.—This well known firm was registered as a limited liability company on the 24th inst.

NORTH STAFFORDSHIRE, 25th April, 1888.

The Pottery Trade.—Manufacturers are working on orders booked some few weeks ago, most of them derived from the American market. The feeling in this staple trade of the district is of a more hopeful character than that which prevailed a few months ago, although no material advance in prices has yet been secured.

North Staffordshire Chamber of Commerce.—At the meeting of this chamber held last week, the question of applying to the Government to constitute the Pottery towns a county under the Local Government Bill was discussed. It was unanimously felt that the close affinity of manufacturing and commercial interests which exists in the Potteries as a whole, would be materially benefited and strengthened by union in a county, and that there were ample grounds for making the application referred to. The proposal is that Longton, Fenton, Stoke, Hanley, Burslem, and Tunstall, which now form one uninterrupted line of separate towns, should be amalgamated. From whatever point of view the matter is regarded, and more particularly from an industrial one, there can be no doubt that the formation of the Potteries into a county for local government purposes, will conduce to the welfare of that commercial centre.

BIRMINGHAM, 25th April, 1888.

The Iron Trade.—The new quarter has opened rather quietly in the iron trade. There is some uncertainty as to prices, and new orders are far from plentiful, especially for high class iron. Makers of the common varieties are better off. The galvanisers have had to give way in price, with the result that orders are being booked more freely; the rates are £11. 5s. to £11. 10s. for 24-gauge, free in Liverpool. There is a fair demand for constructive iron work, and steel is in good request.

The Hardware Trade.—This trade is fairly busy, and the rise in copper has imparted strength to the market by increasing confidence in the maintenance of the price of metals. Most of the manufacturers of tools and implements used in agriculture are busy, both for the home trade and for the Colonial markets. The indents from the Cape continue to indicate sustained prosperity in that quarter, and South Africa and South America are also both absorbing a large quantity of goods. Australian and American requirements are not large, but Canada and the northern ports of Europe are evincing a disposition to buy freely just at present. The approach of the travelling and building seasons is rendering the makers of ironmongery and carriage furniture rather busy. The unfavourable situation of silver as a medium of exchange is telling heavily against trade with India. Burmah, however, is gradually creeping forward into the position of a market for goods such as corrugated sheets and agricultural implements.

DERBY, 25th April, 1888.

Textile Fabrics of Japan.—At a conversazione given last Thursday by Mr. Bottomley, the president of the Derby Chamber of Commerce, Mr. Charles Holme gave an account of the textile industry of Japan, which he illustrated by a display of specimen fabrics. Amongst these were some rare specimens of the dyer's art, the designs on which had been obtained by methods which show the patience and laboriousness of that people. In one case the outline of a complicated geometrical design had all been drawn by hand with a certain composition. When this composition dried it raised a wall which was impenetrable by the dye stuff; the outline of the design was left untouched, while the various portions of the pattern were dyed with different colours. After this had been done, the piece was subjected to the action of steam, which softened and removed the stiff composition. Another specimen, although produced by a totally different method, was no less noticeable. The design in this case was obtained by small squares, about $\frac{1}{25}$ths of an inch across, arranged in rows and forming the outlines. Each of these squares had been formed by raising the fabric at that point and tying the slight elevation with a piece of string, through which the dye could not penetrate. The fabric thus prepared was steeped in the dye, which covered every portion except those parts protected by the strings. When the strings were untied, the design remained in the form of little squares, having the original colour of the fabric on a ground of colour imparted by the dye. It is clear that such productions take rank more as works of art than of industry, although they are not so costly as might be imagined, on account of the wages of a skilled Japanese workman being much lower than in England.

LEICESTER, 25th April, 1888.

Wool Spinning and Yarn Trades.—Trade continues to remain in an unsatisfactory condition. The recent London wool sales have tended to sustain the late quotations for the raw material, but have not in any way improved the market. There is no confidence in the stability of prices, hence transactions continue to be for only small amounts. Country dealers and growers still hold on, but owing to the small demand staplers do not press operations, and as the season advances the holders will part at a reduction. Spinners buy frequently, as their stocks of raw material are, as a rule, not heavy. Orders for spinners are neither large nor plentiful, and most of the mills are not working up to the average. Prices have to be cut so low to obtain commissions as to make the bulk of the trade very unremunerative. Yarn merchants find much difficulty in doing business, as consumers are holding off in anticipation of lower quotations.

Hosiery Trade.—The late alteration in the weather has caused some improvement in the plain department, and there has been an increased demand for cashmere goods; but the trade is done at very close rates, and profits are very small. Cotton goods are very slack in demand. Business is somewhat better in the fancy branch, but there is still room for great improvement.

BARROW-IN-FURNESS, 25th April, 1888.

Iron and Steel.—The market for Bessemer pig iron is briskly maintained because of the great demand on the part of steel makers. Large orders for steel are being offered on home and foreign account, and these will insure an active period for some time to come. Prices, however, are unchanged. Bessemer in parcels of mixed numbers is quoted at 43s. 6d. to 44s. per ton net f.o.b.; and steel rails of heavy sections are quoted at from £3. 18s. 6d. to £4 per ton net f.o.b., and at £4. 3s. 6d. to £4. 5s. for lighter sections. These prices have now practically ruled the market for a month. In the ordinary hematite pig iron trade the business being done is comparatively slow, and prices range from 42s. 6d. to 43s. per ton net f.o.b. There is no diminution in the number of furnaces in blast, nor in the output of pig iron, although stocks remain very large in the hands of the holders of warrants. Makers hold some stocks, but generally speaking they do not represent any great weight of iron. In the steel for shipbuilding purposes there is a brisk business being done. Makers are very fully supplied with orders, and are preparing to increase their output by doubling the productive capacity of their mills. There is every indication of a good trade in the immediate future of shipbuilding, and this is doubtless one of the reasons why at the present moment makers of plates and angles are in receipt of so many inquiries. Plates are quoted at £6. 17s. 6d. per ton net f.o.b., and angles at £6. 17s. 6d. There is a brisk trade also in billets at £3. 18s. 6d., a growing demand for blooms at £3. 15s., principally on American account, and a steady and active industry in tin plates, which are being bought largely, both for the home and foreign markets.

MIDDLESBROUGH, 25th April, 1888.

Pig Iron.—There is still the same depressing influence at work on the market caused by the political situation, whilst an increasing trade is steadily resisting the depression. Makers, indeed, are so confident of better times being close at hand, that they will not lower their prices. No. 3 has been bought for 31s. 9d., but not in any quantity, and sellers who are strong enough to hold out are asking 32s. Makers, as a rule, will not part with their iron under 32s. 6d. Connal's warrants are fluctuating. The price of these is declining, notwithstanding the reduction of the stocks and the increased shipments. Forge iron has for some time now been in good request, and the consequence is that the stock has been almost entirely cleared out in the case of mottled and white. The price has in consequence been abnormally high.

Tees' Revenue.—The surest sign of an increasing volume of trade, is the fact that the revenue of the Tees Commission is increasing month by month. The total dues received on ships and goods for the month of March amounted to £5,357. 7s. 6d., being an increase of £400. 18s. upon the amount received for the corresponding month of the previous year. The total receipts for the five months of the financial year amount to £25,784 16s. 2d., being an increase of £2,026. 5s. 3d. over the corresponding five months of the previous year.

NEWCASTLE, 25th April, 1888.

Iron.—There is at last a prospect that the two large blast furnaces belonging to Messrs. Bell Brothers, at Low Walker, which have stood idle for several years, will once more be utilised for productive purposes. The furnaces were re-built a couple of years ago, and an immense quantity of ore was at the same time accumulated on the premises. Owing to the extreme flatness of the pig iron trade at that period, however, it was not thought advisable to light up, the intention being, no doubt, to await a more favourable opportunity for commencing operations. That time appears to have now arrived, for a dredger was set to work a few days ago to deepen the mooring place beside the quay, so as to allow steamers or sailing ships to take in pig iron, or discharge ore, without the intervention of lighters. Other preparations are also being made for starting the furnaces at an early date, and it is not improbable that the first "charges" will be put in by the end of May. The machinery at the Walker rolling mills, which have also been standing for some years, is now being taken to pieces, but for what purpose has not at present transpired. The iron works at Jarrow and Gateshead continue to work steadily, and the tone of the finished iron trade is on the whole very healthy.

Steel.—The second Siemens-Martin furnace, which Messrs. Hawks, Crawshay, & Sons have erected in connection with their Park Road rolling mills, is now completed, and will be put in operation in the course of a few days. The furnace which is now working will then be temporarily stopped for repairs; but afterwards both furnaces will be kept going simultaneously. At present the output of these new steel works falls far short of current requirements, and it is considered likely that the putting down of other furnaces will not be long delayed. The producers of steel and iron sheets are still exceedingly busy, and for these classes of goods prices continue to be firm.

Chain Works.—The chain making department of Messrs Abbot's works, Gateshead, is still idle, owing to the continuance of the wages dispute recently referred to.

Bridge Works.—The bridge shops at Messrs. Hawks, Crawshay, & Sons' works are just now rather slack; but Messrs. T. Alder & Co., Heworth Shore, are busy with the construction of two iron bridges for India.

The Coal Trade.—The demand for steam coals continues to improve, and prices are tending upwards. The shipments of coal and coke from Tyne Dock for the week ending 21st April were, however, less by over 21,000 tons than those for the corresponding week last year. This falling off was doubtless due to the unfavourable weather, which hindered the departure of vessels.

DUNDEE, 25th April, 1888.

Flax and Jute Trades.—During the past fortnight business in both branches of the trade has improved in tone. Advices from New York indicate a firmer market for jute goods. In the linen branches, although prices are unaltered, a steady business is being done. The demand for flax on the spot is not brisk, as recent large purchases on contract are now beginning to arrive, and consumers are well supplied. Manufacturers' stocks of yarns are low, and an extensive business has been done. In most cases late prices have been accepted, but spinners now incline to be firmer in their demands. Makers of linen goods are well employed, and the outlook is encouraging so far as the finer class of linens is concerned. American orders are coming in freely, but the home demand is not equally active. The heavier classes of goods are somewhat difficult to dispose of, and the tendency of prices is rather against buyers. There is not much doing in sail cloth. The prospects of the new jute crop are favourable, there having been heavy rainfalls in the growing districts. Some new crop has been sold in London at from £12. 5s. to £12. 10s., good first marks. There have recently been large arrivals of last season's crop. For jute yarns there has been more inquiry, and the tendency is to advance rates. More jute goods are being bought.

DIAGRAMS RELATING TO THE PROPERTIES OF WATER AND SATURATED STEAM.

I.

By Professor R. H. Smith.

In the scientific practice of steam engineering one has frequently to make calculations based on the physical properties of water and steam. Our knowledge of these properties, so far as it is accurate, is chiefly due to Regnault's experiments. The direct and calculated results of these and later experiments have been set forth in the form of numerical tables. These tables are deficient in two respects: (1) Although they contain the elements from which all quantities appearing in steam calculations can be reckoned, still this reckoning often entails the loss of considerable valuable time. For practical purposes we want a larger number of tables giving these elements combined in a larger variety of useful forms. (2) The accurate use of the numerical tables involves troublesome interpolation. The interpolation actually always adopted is linear (*i.e.*, by simple proportion); any other would use up too much time. But for very few of the tables is linear interpolation at all exact; indeed, when the interpolation is to be only linear, it is little less than absurd to tabulate the quantities and their differences with five or six significant figures, when the difference is from $\frac{1}{10}$ to $\frac{1}{100}$ even of the quantity itself. By reference to the curves on the diagrams connected with these articles, it is easy to obtain any number of illustrations of the degree of error resulting from linear interpolation. To do so one has only to lay a straight edge between two points on the curve corresponding to two successive values in the numerical tables, and note the deviation of the straight line from the curve. The interpolation in English tables is peculiarly inconvenient, because these are usually tabulated for successive temperatures, 9°F., 18°F., or 27°F. apart. This results from the tables being simple translations from the French, the 9°F., 18°F., and 27°F. corresponding to the much more convenient intervals 5°C., 10°C., and 15°C. Again, it is not with a knowledge of the temperature, but much more commonly of the pressure, that one refers to the tables; and the tabulated pressure having quite odd fractional parts, the interpolation becomes still more awkward.

The employment of fairly drawn curves instead of numerical tables does away at once with all the inconvenience and inaccuracy of interpolation, and in other ways saves a world of trouble. The saving of trouble in these matters is of great scientific importance; because those acquainted with practical office work will readily acknowledge that the necessity of employing intricate and very tedious calculations simply prohibits the use of the method involving them, from sheer lack of time and weariness of spirit. The curve is continuous, and the result desired is read off directly, without error, and without calculation.

The advantage of a curve over a table of numbers in enabling one to grasp the general law of variation is well and widely understood. The present writer considers it a further important advantage that the impossibility of reading from curves with excessive minuteness prevents those engineers who use them from making ill use of their time by dealing with absurdly long strings of figures. The curves shown on the diagrams connected with these articles have been accurately reduced from others of rather more than twice the size, but the scale of the two-page engraving is sufficient for all ordinary purposes. A very few of these curves have been published in such books as Rankine's "Steam Engine," but to so small a scale as to render them rather simple illustrations of the general law, than accurate tables of reference for the various exact quantities.

In connection with these articles it is intended to publish two diagrams on two double-page supplements, one of which (Diagram I.) will be found in this week's issue, while the other (Diagram II.) will appear with the second article. It is hoped that both diagrams may find a place in drawing offices and other places where calculations in steam engineering frequently require to be made.

In the first diagram twelve distinct curves are given, corresponding to twelve complete and continuous tables ranging from 60°F. to 430°F. Although each curve has for its vertical co-ordinate the temperature, still it is as easy to find a quantity corresponding to any given pressure as to any given temperature. If the pressure be known, one has only to find the corresponding point on the pressure curve, and from this point to run along the horizontal line to the curve from which the desired quantity is to be read.

There is only one vertical scale, viz., that of temperatures, in Diagram I. There are, however, three horizontal scales for the various quantities tabulated. One of these is marked P, and is used for the pressure curve. A second scale is marked V, and is used chiefly for the volume curve. Most of the other curves represent quantities of energy—heat energy and mechanical energy spent in doing mechanical work. These quantities are all given in foot-pounds, the foot-pound unit being more convenient for engineering calculations than the "English heat unit," which latter is 772ft.-lb. The third scale, marked E, is that to which these various quantities of energy are plotted.

The twelve curves or graphic tables are the following:—

1. Total Heat of Water from 60°F.—This is the heat needed to raise 1lb. of water in temperature from 60°F. to any other temperature read off on the vertical scale. It is reckoned from 60°F. because one may always without serious, or almost without appreciable, error take this as the average feed water temperature, unless the feed be from a hot well. The curve is nearly, but not quite, a straight line; the deviation being due to the slight variation of the specific heat of water.

2. Pressure of Saturated Steam.—This is given in pounds per square inch, and is to be read to Scale P. The diagram runs down to 60°F. for the sake of condenser pressures. At 60°F. the pressure is only $\frac{1}{4}$lb. per square inch. Below 200°F. the pressure curve to Scale P slopes so very little, and the ordinates are so small, that in order to enable the pressures corresponding to different low temperatures to be accurately distinguished, this part of the pressure curve is drawn out a second time, with the horizontal scale increased ten times. Of course, the Scale P can still be used; but, for example, 25 on scale P must be read as meaning 2·5. The full line pressure curve is plotted directly from Regnault's experiments. The dotted curve represents the author's approximate formula $p = \left\{ \cdot 005644\, t + \cdot 4360 \right\}^{\frac{100}{18}}$ where t is the temperature on the ordinary Fahrenheit scale. The three constants of this formula are so chosen as to make the curve coincide with Regnault's curve at $\frac{1}{10}$lb., 45lb. and 300lb. per square inch, and to give at 212°F. the pressure about $\frac{3}{4}$lb. per square inch too high; it being considered that for engineering purposes it is more important to get a coincidence at low condenser pressures, at medium and very high boiler pressures, than at 212°. In using these graphic tables, however, readings should always be taken from the full in preference to the dotted curve. The pressures tabulated here are "absolute," *i.e.*, from zero (not in excess above atmospheric pressure).

3. Specific Volumes of Saturated Steam.—These are given in cubic inches per pound of steam; and the upper part (from 212°F. to 430°F.) is drawn out a second time with horizontal ordinates increased ten times to make it more readable. For this enlarged curve 100,000 on Scale V must be read to mean 10,000 cub. in. per pound.

4. Latent Heat of Evaporation of Steam.—Scale E gives this in foot-pounds of heat energy per pound of steam. It is nearly but not quite a straight line.

5. Total Heat of Saturated Steam from 60°F.—This is read to Scale E in foot-pounds per pound of steam. It is reckoned from 60°F., as this is the average feed temperature. Its horizontal ordinate is the sum of those of 1 and 4, and it is, therefore, also very nearly a straight line.

6. P (V − w).—The so-called latent heat tabulated in 4 is the total heat that has to be supplied to effect the evaporation; but not the whole of this is absorbed, because during the evaporation the steam does mechanical work in expanding against resistant surrounding bodies, and part of the heat energy supplied is immediately spent in doing this work. The amount of this work in foot-pounds per pound of steam evaporated is tabulated by the P (V − w) curve. It is plotted out twice: first, to Scale E, in order that its amount may be readily comparable by eye with the latent and total heats; and secondly, to ten times that scale, in order that its amount may be accurately read off, this being, perhaps, the most important of all the curves from a mechanical point of view. It runs from about 45,000 foot-pounds when the steam pressure is about $\frac{1}{4}$lb. per square inch, up to about 66,000 foot-pounds at 300lb. per square inch pressure. Its rate of increase decreases only slightly towards the higher temperatures and pressures. 66,000 being just double 33,000, it is useful to remember that one boiler mechanical horse power is afforded by the evaporation of $\frac{1}{3}$lb. of water per minute, or 30lb. per hour, to steam at 300lb. per square inch absolute pressure. This quantity is found by multiplying P, the pressure, by the excess of the volume of steam (V) over the volume of water (w).

7. $\left\{ \text{L} - \text{P}\,(\text{V} - w) \right\}$.—This is called the *real latent heat*. It is the apparent latent heat (L) minus the quantity of heat not really absorbed, but spent in doing mechanical work during evaporation. Scale E gives it in foot-pounds per pound of steam evaporated. It is the difference between Curves 4 and 6.

8. $\left\{ \frac{\text{L} - \text{P}\,(\text{V} - w).}{\text{V}} \right\}$.—This is the last quantity calculated per cubic foot of steam evaporated instead of per pound, as in Curve 7. It is often found more convenient to have it per unit of volume.

9. Total Heat from 60°F. *less* P (V − w).—This, also to scale E, is that part of the total heat which is really absorbed, the rest being spent in doing the evaporative mechanical work. It is the difference between Curves 5 and 6.

10. Ratio of P (V − w) to Total Heat from 60°F.—This is the proportion of the whole heat spent in raising the steam from feed temperature 60°F. that is developed in the form of mechanical work done during evaporation. It is the $\frac{\text{B.M.H.P.}}{\text{B.H.H.P.}}$, or boiler mechanical horse power divided by boiler heat horse power, explained in a series of articles by the author a few months ago (see *Industries*, Vol. III., page 1). This is a numerical ratio. To avoid multiplying scales, the volume scale is utilised for this curve, unity being represented by 10,000,000 on Scale V. Thus the ratio runs from ·053 at very low pressures up to ·073 at the top of the diagram.

11. Ratio of Total Heat to P (V − w), or $\frac{\text{B.H.H.P.}}{\text{B.M.H.P.}}$—This is simply the reciprocal of the last quantity. It is often convenient to be able to find this reciprocal by reference to a table such as this; indeed, this quantity is of more frequent practical use than 10. It is to be read by help of Scale V, 100,000 on that scale representing unity. Its value runs from 18·8 to 13·8.

12. Total Heat from 60°F. Divided by Latent Heat at 212°F.—In tests of boilers the actual evaporation is usually reduced to an equivalent evaporation of feed water taken at 212°F. into steam at same temperature. This reduction is performed by finding the ratio of the actual heat supplied in the boiler to each pound of water, taken here at 60°F. feed temperature, to convert it into steam to the latent heat of evaporation at 212°F., and multiplying the actual evaporation in pounds of water per pound of fuel by this ratio. For convenience in making this reduction this ratio is tabulated by this last curve. It is read on Scale V, 1,000,000 on that scale representing unity. The ratio runs from 1·11 to nearly 1·23.

(To be continued.)

THE LATE MR. THOMAS R. CRAMPTON.

It is with regret that we record the death of Mr. Thomas Russell Crampton. Mr. Crampton had been in failing health for some time before his death, and passed quietly away on the evening of the 19th inst. He was born in 1816, at Broadstairs, Kent, and after receiving a liberal education at a private school was articled to Mr. John Hague, of London, where he obtained a knowledge of mechanical engineering, and was at the time a fellow pupil of Sir Frederick Bramwell. After serving his pupilage he was engaged under the elder Brunel for several years, and afterwards with Mr. Gooch, under whose direction he designed the first locomotive for the Great Western Railway. He afterwards held a responsible position under Messrs. Rennie, and in 1848 commenced practice on his own account as a civil engineer. Between the years 1842-7 Mr. Crampton perfected the type of locomotive bearing his name, and in which a long boiler, outside cylinders, and a low centre of gravity are the essential and distinguishing features. A locomotive on this principle was built and run on the London and North-Western Railway, and was a special feature at the Great Exhibition of 1851, where it obtained for its designer the grand medal. In that year Mr. Crampton succeeded, under exceptionally difficult circumstances, in laying the first successful cable for a submarine telegraph between Dover and Calais. He undertook the whole engineering responsibility in this pioneer work of submarine telegraphy. Among the numerous other works executed by Mr. Crampton, either by himself or in conjunction with others, may be mentioned the Berlin water works, in which he was associated with the late Sir Charles Fox; the Ottoman Railway from Smyrna to Aidin; the Varna and Rustchuk Railway; the East Kent Railway from Strood to Dover; the Herne Bay and Faversham Railway; the Sevenoaks Railway to Swanley, and after the various lines became absorbed into what is now known as the London, Chatham, and Dover Railway, he was interested in the construction of other portions of that system. Mr. Crampton took an active part in the controversy on broad *versus* narrow gauges for railways, known as "the battle of gauges," in which he advocated the narrow gauge. Besides his improved locomotive, he invented a furnace for burning powdered fuel, revolving furnaces for the manufacture of iron and steel, brick making machinery, cast iron forts, and tunnel boring machinery. Mr. Crampton was a prominent member of the leading technical institutions, and, until his health gave way, took an active part in the discussions on the various subjects brought before them, especially those relating to matters which had occupied his attention in early life.

Industries:

FRIDAY, 27TH APRIL, 1888.

INDUSTRIAL ACTIVITY AND THE CONSUMPTION OF COAL.

IT is a generally accepted maxim that the consumption of coal at any given time is a true measure of industrial activity in the country in that period. Hence we find manufacturers and political economists constantly adducing as irrefragable evidence of reviving or languishing industry and commerce, the animated or depressed state of the coal trade; and we as often see colliery owners and those who distribute the produce, merchants and shipowners, anxiously watching for indications of the probable course of the coal trade among the circumstances and influences which determine that of the great manufacturing industries. Up to a certain point the reasoning of both parties is just. They know that some four-fifths of the coal consumed in this country is burned to generate steam, or to serve some other industrial purpose, and it is obvious that a greater or less production of manufactured goods must augment or diminish the demand for coal. But the question is not one of this degree of simplicity. The consumption of coal is, no doubt, a measure of industrial activity; but it is at the same time a measure, in some degree, of scientific progress. We have not gone on year after year burning a pound of coal to produce a certain effect. On the contrary, the effect produced by the pound of coal has constantly and steadily increased, in consequence of wider and more accurate knowledge. Hence, the standard by which we measure our industrial activity is continually changing. We have here an explanation of the blunder so often fallen into of late by writers and public speakers who have dealt with the question of reviving trade. The mineral statistics issued from the Mining Record Office are made to show that the recent period of depression in trade was, despite all statements of well informed persons, and other evidence, to the contrary, not only one of low prices, but also one of greatly restricted production; and the conclusion thus arrived at is made use of whereon to base a prediction concerning the immediate future of the coal trade. This erroneous teaching is a matter of more serious consequences than it appears at first sight to be; for not only does it tend to obscure the prospect and puzzle the inquirer, but false hopes are raised or undue depression caused in those who, from the active participation in our great national industries, have need of a true estimate of the influences operating to direct the course of events. This is true in a special manner of colliery owners and all occupied in the coal trade. For a long period of years the production of coal steadily increased, till in 1886 it reached the colossal figures of 160,000,000 tons. This was a quantity somewhat in excess of the requirements, and since that date the output has diminished. The falling off is attributed wholly to the depression of trade generally, which, by restricting production, occasioned a smaller consumption of fuel in the great coal consuming industries; and it is argued that the revival which is now in progress must necessarily be attended with a larger demand for coal. If this be a valid conclusion, we are on the eve of a period of increasing activity in the coal trade, and consequently of greater prosperity for the mining industry. But there is yet no sign of improvement, notwithstanding the generally admitted fact that trade and commerce have revived, and that there is now considerably more activity in some manufacturing industries than there was a year ago. How is this fact to be accounted for? The answer would seem to lie in the changing character of fuel consumption as a standard of measurement. And if it be true that we have in this circumstance a sufficient explanation of the apparent contradiction, we must cease to expect, for some time to come at least, a resumption of that progress which in the past has marked the development of coal mining in this country in the matter of output.

From an industrial point of view, one of the most noteworthy results of the growth of knowledge in recent times is the reduction in the quantity of fuel burned to produce a given result. The blast furnace practice of the present day, for example, contrasts strongly with that which prevailed at the beginning of the second half of the current century. Instead of 1·50 to 2 tons of coke, we have now but 0·80 to 1 ton consumed in the operation of smelting 1 ton of pig iron. The change has taken place gradually and continuously, so that we find a distinct and important improvement even when we take a shorter period for our comparison, say the last ten years. The full significance of this change will be perceived by considering it in relation to the annual production of 7,500,000 tons of pig iron in this country. A similar saving of fuel has been effected in other metallurgical operations. Of even greater importance than this progress in the science of metallurgy, is the saving effected in the cost of generating steam. Here our growth in knowledge has enabled us to make a still more striking contrast with past times. The adoption and extension of the compound system, combined with numerous improvements in the detail of boiler and engine construction, have led to economy in the matter of coal consumption so great that we shall be well within the truth in asserting that the weight of coal which twenty years ago it was necessary to burn to obtain one horse power in steam, now yields two horse power. The progress here indicated has been gradual, as in the case of blast furnace practice; that it has not occasioned a corresponding gradual shrinkage in the home trade in coal is due to the fact that its effects have been counteracted and masked by new applications of steam power throughout the same period. But we have now reached a stage of development in our industrial and commercial life in which comparatively few new applications are possible. The change from hand to machine labour is complete. Our country is covered with a network of railways that admits of no further important extension, and our commerce is restricted by the competition of foreign rivals. For this reason the effects of the reduced consumption of fuel to perform a certain amount of work are now making themselves felt, and hence proceeds the languor which persists in the coal trade despite the greater activity prevailing in other branches of industry. Let us take, as another illustration and proof of the truth we are seeking to enforce, the remarkable progress made within the last few years in marine engineering. Here the adoption of the compound system of engine, often in its highest development of triple expansion, and in a few recent instances of even quadruple expansion, has led to notable economy in fuel. In these circumstances we cannot assume that the 6,868,790 tons of coal shipped from our shores last year for the use of steamers engaged in the foreign trade, represents, when compared with the shipments of 6,400,594 tons in 1883, an increase of only 7·3 per cent. in the

Digitized by Google

horse power expended in that trade. Thus we cannot validly deduce the conclusion, in this or in any one of the preceding cases, that a smaller consumption of fuel necessarily implies diminished industrial activity.

An obvious inference from the foregoing facts is that there must be a constantly increasing volume of trade to maintain the consumption of coal stationary in quantity. To put this truth in another way, a consumption of coal that is sensibly stationary over a given period implies a steadily increasing degree of activity in our manufacturing industries. In this way we may, without risk of error, use it as standard of measurement. The lessons, of no small practical utility, to be learned from this view of the question under consideration are briefly these: (1) The actual state of the coal trade, which shows little or no advance on that of 1887 and 1886, is not in contradiction with the evidence of reviving trade generally which we discover in other directions. On the contrary, it is to be accepted as proof of steadily increasing activity. (2) Colliery owners, colliers, and all occupied in the coal trade who are building up hopes of more active markets on the evidence of revival in our manufacturing industries, are probably preparing the way for bitter disappointment. A genuine and lasting revival of trade must be one which proceeds gradually and slowly, and such, we have reason to believe, is now in progress. Moreover, with the keen competition we have now to contend with, it is hard to conceive how a return to prosperity can be other than slow. But a progress of this character, for reasons already stated, is incapable of augmenting in an appreciable degree the consumption of coal in the country. Fluctuations there may and probably will be; but we are considering only average results. (3) Manufacturers may reckon on cheap coal for some years to come. Production is now slightly in excess of consumption, and there are heavy stocks at the pits. Under these conditions it seems in the highest degree improbable that within the next few years the circumstances of trade will so far change as to force the demand above the supply.

THE EDISON GLOW LAMP PATENTS.

The action of the Edison and Swan United Electric Light Company, Limited, *v.* Holland and others, was commenced at the Royal Courts of Justice, before Mr. Justice Kay, on Tuesday, the 17th inst., to restrain the infringement of Edison's patent for the filament, No. 4576 of 1879, and Cheesbrough's Sawyer Manns "flashing" patent, No. 4847 of 1878. The Attorney-General (Sir Richard Webster), Mr. Aston, Q.C., Mr. Moulton, Q.C., and Mr. Bremner, instructed by Messrs. Ashurst, Morris, Crisp, & Co., appeared for the plaintiffs; and Sir Horace Davey, Q.C., Mr. Finlay, Q.C., and Mr. J. C. Graham, instructed by Messrs. Renshaw, appeared for the defendants. Our readers will recollect that these two patents have already been the subject of litigation, in the case where Messrs. Woodhouse & Rawson were the defendants, and in that case the plaintiffs were successful, both before Mr. Justice Butt, who tried the case in the first instance, and subsequently in the Court of Appeal. The present case is one of very considerable importance both to the public and to the electrical world, because if the defendants succeed in establishing the invalidity of those patents, the manufacture of glow lamps will be thrown open to the public.

The case came into Court in the following manner: Mr. Holland, the well known caterer, had purchased the lamps complained of by the plaintiffs from the Jablochkoff Company, for the purpose of illuminating the Albert Palace at Battersea; that company had purchased them under an indemnity from the Anglo-American Brush Electric Light Corporation, Limited, and the last named company obtained leave to defend the action, and are therefore the real defendants in the action. The Attorney-General opened the case by describing the inventions contained in Edison's and Cheesbrough's specifications, and pointed out that among the merits of Edison's invention, one of the most conspicuous was the carbonising of the filament after it had been formed into a filament. He dwelt upon the fact that no incandescent lamp which could be called a practical success, had been made, or even described, before the date of Edison's patent, and that soon after that date such lamps were made and sold, and have since been made and sold in millions. He pointed out that, so far as the plaintiffs were aware, the only lamp which came at all near to Edison's was one which had been made by Mr. Swan, some time very early in 1879 or in the autumn of 1878, at Newcastle, where it had been publicly exhibited by him at lectures. This lamp, which was produced in Court, contained a thin straight pencil of carbon of circular section about 1¼in. long and $\frac{1}{25}$in. in diameter, enclosed in a glass egg-shaped vessel, from which the air had been exhausted. The carbon pencil was supported at each end by platinum wires fused into the glass. Sir Frederick Bramwell was the first witness called on behalf of the plaintiffs. He was examined by Mr. Aston, and cross-examined at some length by Mr. Finlay, who endeavoured to elicit from him the fact that Edison had not given sufficient information to enable that hypothetical person, the skilled workman, to carbonise a filament, more especially by reason of his having omitted to state that in carbonising it is absolutely necessary to take elaborate precautions to exclude the air from the vessel in which the filament is carbonised. Sir Frederick Bramwell stated that in his opinion the vessel in which the carbonisation was effected might be packed with sand, so as to exclude the air, and that this would succeed. Sir Frederick Bramwell was asked whether he had ever seen any lamps made in this country according to Edison's specification pure and simple, without any additions; and although he at first stated that he had seen one lamp so made out of a carbonised cotton thread, he subsequently admitted that the cotton thread which he had seen carbonised had been treated with sulphuric acid so as to parchmentise it before carbonisation, and that he had never seen Edison's directions pure and simple followed. Sir Frederick Bramwell was then pressed to point out the advantages to be obtained from the use of a filament, and was unable to point out any except that of high resistance. The witness admitted that electricians at the date of the patent were perfectly familiar with the laws of electricity, and knew both how to obtain high resistance, and what were the advantages resulting from it; and this was more especially the case with Mr. Lane-Fox, who had explained the whole theory of electric lighting in a marvellously clear manner in several specifications of his patents taken out before the date of Edison's patent. In fact, had Mr. Lane-Fox only made use of the term carbon in his specifications, he would apparently have given all the information to the world which the plaintiffs now wish to place to the credit of Mr. Edison. The witness was asked to explain in what respect Mr. Swan's lamp differed from Edison's. At first the witness endeavoured to differentiate them by suggesting that the pencil of Swan's lamp had been cut out of a larger piece of carbon, that is to say, had not been in the form of a pencil before it was carbonised; but here again, when pressed, he admitted that he knew little about Swan's pencil, and that it might have been made either way. Upon various chemical points, arising on both Edison's and Cheesbrough's specifications, more especially upon a very remarkable passage in the latter—in which Cheesbrough says that his invention is not confined to the treatment of carbon alone, but includes many infusible non-conducting bodies—Sir Frederick Bramwell gave no opinion, preferring to leave them to the chemical witnesses. The next witness called on behalf of the plaintiffs was Dr. John Hopkinson, who agreed generally with Sir Edward Bramwell except upon the question of the use of sand for excluding the air in carbonisation. He thought that a competent working man would know that he must avoid using sand, the use of which would certainly lead to failure in the case of fine filaments, inasmuch as they would, without doubt, be burnt in the carbonising vessel by the air contained in the interstices of the sand. Dr. Hopkinson expressed a decided opinion upon the chemical questions arising on the specifications of both Edison and Cheesbrough; but, like the last witness, he admitted that he had neither made nor seen any experiments on the subject. Mr. John Imray was then called. He too had not made any lamps according to Edison's specification, but he had made certain experiments as to the electrical properties of certain lamps which had been made by some person in the employment of the plaintiffs, and which, he was told, had been made according to Edison's specification. Nearly all these lamps had the globes dimmed and discoloured. Sir Horace Davey asked the witness to point out any material point in which one of the lamps, produced by Mr. Imray, made from cardboard and said to be constructed according to Edison's specification, differed from Swan's lamp. The witness was apparently unable to point out any material distinguishing feature. Mr. Gimingham was next called, and stated that he had followed precisely almost all the different methods described by Edison for making a filament, and had succeeded in the whole of them. He further stated that he had tried the lamps so made for duration, and found the average life of the lamps to be a considerable number of hours. The last witness for the plaintiffs was Dr. Fleming, the electrician of the plaintiffs, who agreed in the main with the evidence given by the others. He, however, stated that secret processes were used in every stage of the manufacture of lamps by the plaintiffs, an admission which was scarcely consistent with the opening remarks of the Attorney-General, that millions of lamps were made by the plaintiffs according to Edison's specification.

No other witnesses were called, and Mr. Aston stated that that closed the plaintiffs' case. Sir Horace Davey then opened the defendants' case. He said that he intended to rely upon the following grounds, viz., that Edison's patent was bad for want of novelty; that his specification did not contain sufficient directions to enable a competent working man to make a filament of carbon; and that if the Court construed the specification in the way in which he construed it, there was no infringement, but if it was construed as the Court of Appeal had construed it, he would admit infringement. The case had not concluded at the time of going to press.

CANAL EXTENSION.

In previous issues we have examined the relative merits of canal and railway carriage, and pointed to the necessity, if cheap transit is to be obtained, of a healthy competition between the two systems of conveyance. We described in some detail the scheme for improving the Worcester and Birmingham Canal, and that for opening up communication between Birmingham and London, by an extension and alteration of existing waterways. Reference has also been made to alternative suggestions for adopting the route to Liverpool, or *viâ* the Trent to Hull. If the industrial position of the Midlands is to be maintained and strengthened, the serious inception and rapid completion of one of the projects in question appears to us to be a matter of the highest moment, and for reasons stated in our issue of the 23rd ult. the London route has many advantages over the other schemes, and is best calculated to meet the immediate requirements of the district which it is intended to benefit. A point which engaged the attention of the Ship Canal Inquiry Committee of the Birmingham Town Council is of primary importance, viz., the adoption of adequate precautions to prevent the subsequent acquisition by the railway companies of whatever canal communication is decided upon. In the report of this committee we find the following suggestion made: "The plan of carrying out the work by means of a public trust appears to the committee most likely to insure and preserve the interests of the town, and secure the lowest possible rates to traders and consumers; and it is probable that with such a trust under the operation of a sinking fund, the capital account being ultimately extinguished, the canal might become almost free, such tolls only being levied as would be sufficient to provide for its maintenance. The committee therefore recommend that they be empowered to take such steps as may appear desirable to induce the Government either to insert clauses in their Railway and Canal Traffic Bill, or to introduce a separate measure authorising the formation of canal trusts."

A great contrast is apparent if we compare the advance which has been made in the development and improvement of railway transit with the stationary condition of canal carriage during the past half century. During that period in the former case the rate of travelling has increased from three to four fold, both in the case of goods and passengers. On the other hand, transit by canal is now little less cumbersome and protracted a process than it was fifty years ago; and it is apparent that until our waterways are so widened and extended as to admit of steam propelling power, no material improvement can well take place. While we consider the Birmingham to London route most suited for development in view of the immediate requirements of the Midland district, we may direct attention to a valuable pamphlet, written by Mr. Samuel Lloyd, under the title of "National Canal between the Four Rivers." In it is elaborated a scheme for the intersection of the Midland Counties by water communication, of sufficient ordinary depth to allow of the passage of small steamers, between the Thames and the Mersey and the Severn and the Trent. The contents of this work will doubtless do much towards educating public opinion with regard to the necessity and practicability of taking advantage of England's natural position to insure a complete system of efficient canal transit as a competitor and concomitant of railway carriage. While, as our columns indicate, we do not ascribe all the existing depression in trade in the Midland district to the lack of means for the cheap transit of goods, we point to the removal of this drawback as being likely to afford some alleviation to that and all land locked positions.

Bismarck's Paper Mills.—The Varzin paper mills, the property of Prince Bismarck, which were destroyed by fire last year, have been re-built at a cost of £50,000. These mills are capable of turning out 15 tons of paper a day.

Letters to the Editor.

AN APPEAL FOR THE ROYAL VICTORIA HALL BY LADY FREDERICK CAVENDISH.

TO THE EDITOR OF "INDUSTRIES."

SIR,—May I ask a little of your valuable space for calling attention to a proposed memorial to one whose death was a national loss—the late Mr. Samuel Morley? So deeply was he impressed with the dangers arising from the extremes of wealth and poverty, and the dreary lives led by the very poor, that he used often to speak of Society as existing on a volcano, and spared neither labour nor money to lessen the evils he deplored. Among the many good works in which he was engaged none was nearer to his heart than the Royal Victoria Hall, which has for its object to brighten the lives of the poor by providing healthy recreation (apart from temptations to drink), and opportunities of instruction for those who desire them. The work has been carried on under many difficulties for more than seven years. Once a gift of £1,000 from Mr. Morley (towards buying the remainder of the lease) saved it in a crisis, and from that time he regularly took the chair at the committee meetings. It has occurred to those who worked with him there, that there could be no more fitting memorial of his unselfish life, none more in accordance with his own wishes, than to establish this work on a permanent basis. During his lifetime he caused inquiries to be made as to the possibility of buying the freehold; but the then owner refused to sell, and there appeared to be no prospect for the future, but that the hall should relapse at the end of the lease (which has now ten years to run) into the state from which the present trustees rescued it. What that state was we may learn from the pages of "Alton Locke," or from the reports of any of the police who frequently helped to take thirty or forty from the old theatre to the lock-up on public holidays. But an opportunity offers now of making a return to the old horrors impossible. The ground landlord is willing to sell the freehold, and the trustees' committee propose to raise a memorial fund to buy it. If they succeed, the Charity Commissioners will take over and manage the hall for the future, as part of the scheme for People's Palaces in South London. In that case there would be no more appeals to the public for the Royal Victoria Hall; its future would be provided for, and Mr. Morley's name associated for ever with the work he did not live to finish. But the proposal is for the Commissioners to meet the public with an endowment, after the freehold has been bought, and for this £17,000 must be raised, and unless it is raised by September a deposit of £500 (already paid) will be forfeited. The value of the freehold, we are told, is much more than this. The landlord has abated several thousands in consideration of the public utility of the object, and £4,000 is allowed for the present value of the lease, which is freely given by the trustees and committee. The £17,000 covers the remainder of the price, law expenses, &c. Towards this, individuals on the committee have promised £3,500.

I will not trespass on your space with details of the entertainments, concerts, lectures, technical and other classes, temperance societies, working men's club, &c., all flourishing at the Hall. Let those who wish to know come and see. The popularity of the place is shown by the fact that £1,825 was taken in nine months for admission at the doors, and chiefly in sums of twopence and threepence. All who wish to help in perpetuating the name of a good man in the way he would have chosen, are invited to communicate with Miss Emma Cons, hon. sec., at the Hall, Waterloo Road, S.E. The work is like Mr. Morley's generous sympathy, inasmuch as it takes no account of differences of creed or party, so that all may fitly share in it.

Yours &c.,

LUCY C. F. CAVENDISH.

London, 21st April, 1888.

THE CORROSION OF PROPELLER BLADES.

TO THE EDITOR OF "INDUSTRIES."

SIR,—I was very much interested in the abstract you gave in your last week's issue of the paper by Mr. W. C. Wallace on the material best suited for propeller blades, and should be glad if any of your readers could tell me where—that is, on what portion of the steel blade—corrosion generally takes place. Is it found on the side nearest to the hull or the opposite side? also is it chiefly near the tip of the blade or near the boss? I ask this as I think it is quite possible to prevent it, and at a comparatively small cost. I would also like to know whether steel blades are cast or forged to shape.

Yours, &c.,

Bolton, 24th April, 1888. O. KAY.

PROPOSED LEGISLATION FOR STEAM BOILERS.

TO THE EDITOR OF "INDUSTRIES."

SIR,—The rejection of the Steam Engines and Boilers Bill by the House of Commons, on the 17th inst., is a gratifying confirmation to me of the correctness of the opinion expressed in my letter published in your issue of the 9th ult.—"that the question of certificating attendants might be dismissed from consideration." In face of the overwhelming evidence as to non-requirement of State interference in this matter, it was difficult to imagine any other result. It appears also to be generally understood that Lord Stanley's Registry and Inspection of Boilers Bill is dead, and will not be brought forward by Sir Michael Hicks-Beach; but on the other hand, Mr. Provand, member for one of the Glasgow divisions, has obtained leave to bring in a Bill to provide for compulsory inspection of steam boilers; but as it does not appear to be yet printed, its provisions are so far unknown.

During the years 1882 to 1887 inclusive, 150 deaths have been caused by boiler explosions and accidents to such steam apparatus as are reported upon under the Boiler Explosions Act, 1882. These numbers are taken from the Assistant Secretary to the Board of Trade's fifth annual report. From other statistics I find that 200 persons are killed and about 3000 injured annually by accidents in the streets of London, from various causes. Yet no member of Parliament seems to have discovered what opportunities for Bills, talk, and notoriety might be obtained from this fact. Like the famous authors of the Architects' Registration Bill, some gentlemen, specially qualified by knowing nothing about the subject they are about to take in hand, might bring in a Bill to register and certify all coachmen, cab, 'bus, van, and cart drivers, and to provide for the examination of any person who took reins in hand. As but 150 lives have been lost in five years by boiler explosions, it may be fairly assumed that it would take from one to two years more to increase the number to the appalling annual death rate by accidents in the London streets; and yet no one proposes to make any laws, restrictions, or rules regarding the matter, although six or seven times more fatal in its results. Instead of spending about £50,000,000 capital, and imposing £500,000 annual taxation, for the purpose of attempting to prevent boiler explosions causing an average of thirty deaths per annum, is there not here verge and room enough for a truly valuable effort by M.P.'s in search of a cause and a mission?

In my previous letters to you on this subject, I have constantly urged the importance of the Board of Trade holding "Formal Inquiries" under the Boiler Explosions Act. The first "Formal Inquiry" was held on the 11th, 12th, and 13th January, 1888, upon the explosion of a "Rastrick" boiler at Dudley, which happened in October, 1887. No report, however, has so far been made public, although it is now about six months since the explosion occurred, and upwards of three months since the inquiry was held; this is an admirable instance of the manner in which the Act has been and is being worked—upwards of five years elapse before a "Formal Inquiry" is ever held. Will it be as long before the first report is issued? Why make a formal inquiry at all after so many years, if there has been no sufficient reason in the interim. The Dudley explosion certainly offered no special features rendering it more deserving of notice than many others which have occurred during that time. The ways of the Board of Trade, in relation to the Boiler Explosions Act, are undoubtedly dark, and cannot be "understanded of the people."

Last week, in your extremely interesting and valuable letters on "Foreign Industries," it is stated that "In the beginning of 1883 a law was passed putting boilers erected within the town of Vienna under police regulations; but this law was found to impose too many restrictions upon the owners of small boilers, and thus to damage domestic industries. The owners of small boilers have repeatedly asked for an amendment of the regulations, and now the Vienna Society of Engineers have taken the matter in hand, and, at their last meeting, they resolved to petition the Ministry to pass a new law which would facilitate the employment of small steam boilers." This information is opportune, and supplies just the kind of evidence which might be expected of the result of governmental interference with the working of steam boilers. Here we have the same tendency, as in Lord Stanley's Bill, to oppress the comparatively defenceless small steam user, allowing railway companies and wealthy corporations to take their own unrestricted courses, which should be sufficient warning to the manufacturers and steam users of this country.

Yours, &c.,

Manchester, 21st April, 1888. ECONOMISER.

THE TESTING OF STEEL.

TO THE EDITOR OF "INDUSTRIES."

SIR,—Metallurgists and manufacturers are often confronted when testing steel with results contrary to previous experience, and which do not always appear capable of explanation, either from variations in chemical composition, or the methods of working. For example, it is within my experience that a steel containing traces of silicon carbon 0·17, sulphur 0·03 to ·06, phosphorus ·06 to ·07, manganese 0·40, after corresponding for a time to the mechanical test required, viz., a tensile strength of 27 to 30 tons per square inch, suddenly showed an increase of tensile strength of 31 to 35 tons per square inch, and it was only by reducing the percentage of carbon to ·12 or ·13 that the steel could be made to stand the normal test of 27 to 30 tons tensile strength, while the other constituents remained the same. It may be here noted that sulphur, unlike phosphorus, appears not to affect tensile strength. Steel containing sulphur ·16 per cent., carbon 0·12, stood a breaking stress of 27·15 tons. Another sample containing sulphur ·05, carbon ·13 per cent., stood 27·26 tons. The other constituents, phosphorus and manganese, were practically the same, with only a trace of silicon. The cause of this sudden change in quality could not on inquiry be satisfactorily explained. The steel made at various periods for this particular test was always free from silicon. The sulphur never exceeded ·07, and the phosphorus from ·06 to ·07 per cent. It may be reasonably inferred that the variations in sulphur, judging from the results of testing the abnormal sample containing ·16 per cent. of sulphur, could have no appreciable effect.

I have no doubt that these discrepancies can be confirmed; indeed, I believe it is an open secret that manufacturers have no really reliable chemical method or process whereby steel of definite mechanical quality can be manufactured, consequently they have no resource left but that of continuous mechanical testing and repeated chemical analysis. I understand that some have even gone so far as to altogether repudiate chemical analysis, and assume that iron possesses some unknown property insensible to such analysis, and in some degree beyond the control of the manufacturer. Various fanciful names, such as "body," "nature," "temper," &c., have been assigned to this unknown constituent, or, perhaps, mythical property of iron; but the book has not yet been written which fully explains or defines it. It is often assumed that these unaccountable variations may be due to overheating or undue oxidation; others again maintain that the metal has not been heated sufficiently, or unequally heated, or improperly annealed; in fact, on examination of such steel, experts usually state that the discrepancy observed must be ascribed to one of the causes I have named. It will thus be seen that the anxious investigator is forced to leave matters pretty much as he finds them, and the weary round of trials and tests has to be repeated until in some haphazard manner the object in view has been attained. Having explained the difficulty of steel makers, I may say that I think it probable that a plausible explanation of these differences may be traced to variations in temperature, and that, strictly speaking, steel of a given chemical composition requires a certain temperature at which it must be worked to insure good results. But the question is, What is this temperature? For without knowing it we are practically helpless, and still remain under the domain of "rule of thumb" practice. It appears, however, possible that on due consideration some clue may be obtained to the temperature required. It will, I think, be granted that the fusion point of iron or steel varies with the quantity of foreign matter alloyed with the pure iron; but while admitting this it may be urged that differences only amounting to a few hundredths per cent. of carbon, silicon, or other elements would not materially alter the fusion point. As the results of a somewhat extended experience both in the rolling and heating of steel, I think it probable that this may not be so. All persons daily engaged in manipulating either steel or wrought iron know well that hot or cold rolling makes a great difference, and that the critical welding heat point of the metal admits of but a very narrow limit. In the days of puddling the regulation of temperature was a most important factor. The adjustment of the proper quantity of fettling—the oxide of iron necessary for the oxidation of carbon and silicon, and the removal of phosphorus and other material—could be easily done; but the adjustment of the critical temperature for balling and rolling, so as to secure good results, required some care. More especially in the manufacture of puddled steel it was found that a lower degree of heat sufficed for the balling, &c., which was due to the simple fact that the fusion point of steel was lower than that of wrought iron. At the heat required for the latter the steel remained in a fluid or semi-fluid state, and even with this knowledge to guide the operator we know that it was often a matter of great practical difficulty to decide on the critical point of temperature specially suitable for the best work. I may refer to the fact that the practice at different Bessemer steel works differs in some degree, and that with notable variations in chemical composition rails corresponding to given fixed tests are made. This is especially noticeable as regards silicon, steel containing a sensible quantity of silicon being passed at one works, whilst it is rejected at another, although the same person may conduct the tests in each case. As before suggested, a clue to some of these discrepancies may be traced to variations of temperature. It is well known that steel may be seriously damaged either by under or over-heating. In the first instance the steel may be too hard to pass through the rolls, or even if passed through it may not be sufficiently plastic to yield readily to pressure. We may in that case imagine that minute cracks are formed, which cause a corresponding deterioration in strength. On the other hand, it is known that if we heat steel beyond a certain point it falls to pieces when manipulated, and the reason of this is apparent, for the metal is approaching to the semi-fluid state, and therefore, for the reason given when referring to the puddling process, it cannot be rolled without a reduction of temperature.

It seems, therefore, that for the sucessful working of steel it is not enough to rely entirely on chemical analysis or on simple experience. The foregoing facts would seem to indicate that steel must be worked at a certain fixed, but as yet unknown, temperature below its fusing point, at which heat the flow of heated metal undergoing compression and elongation in the rolls is such as to insure the best practical results. It also follows that if the degrees of heat between these points can be ascertained, it may only be necessary to ascertain the fusion point of any other unknown sample of steel, from which the rolling temperature can be determined; for the welding heat will obviously be a constant range of temperature below this. It seems, therefore, probable that the discrepancies we have referred to are simply due to differences in the temperature of the heating furnace—the welding or rolling heat in one case suitably corresponding to the fusion point of steel with ·17 per cent. of carbon, and in another to that of steel having ·12 to ·14 per cent. of carbon.

Yours, &c.,

METALLURGIST.

South Wales, 20th April, 1888.

CLYDE SHIPBUILDING FOR MARCH, 1888.

THE heavy contracts booked in the autumn are now beginning to tell upon the tonnage launched. In March sixteen vessels were launched, with an aggregate tonnage of 25,015. Nearly one-half of this large tonnage was composed of the 10,500 tons of the "City of New York," built by Messrs. J. & G. Thomson, and launched during the month. The fresh contracts booked during March include a steel screw steamer of 4000 tons, to be built by Messrs. D. and W. Henderson & Co., Meadowside; one of 2800 tons, to be built by Messrs. Russell & Co., of Greenock; a fast paddle steamer for channel service from Dover to Ostend, to be built by Messrs. Denny Brothers & Co.; a screw steamer of 1200 tons, to be built by Messrs. Simons & Co., Renfrew; a screw steamer of 500 tons, to be built by the Ailsa Shipbuilding Company. These and other orders bring up the total of new contracts to rather over 12,000 tons.

The following is a list of the vessels launched during the month: "Algonquin," steel, 1800 tons, built by Messrs. Napier, Shanks, & Bell, for Messrs. Thos. Marks & Co., Port Arthur, for service on Lake Ontario; "Bio-bio," steel, twin screw, 750 tons, built by Messrs. R. Napier & Sons, for the Compania Sud Americana de Vapores, Valparaiso; "Brunner," steel screw, 550 tons, built by Messrs. Macarthur & Co., Paisley, for Mr. Martin Kennedy, New Zealand; "City of New York," steel, twin screw, 10,500 tons, built by Messrs. J. & G. Thomson, for the Inman and International Steamship Company, Limited; "Conscript," composite, screw, 750 tons, built by Messrs. A. Macmillan and Sons, for mail and passenger service on coast of Newfoundland; "Domira," steel, 1800 tons, built by

Digitized by Google

Messrs. Alexander Stephen & Sons, for Messrs. Maclay and Macintyre, Glasgow; "Pharaon" and "Philœ," hopper barges, each 400 tons and 300 h.p., built by Messrs. Lobnitz & Co., Renfrew, for the Suez Canal Company; "Princess Henriette," paddle steamer, 1250 tons, built by Messrs. Denny Brothers & Co., for the Belgian Government postal service between Dover and Ostend; "Princess Louise," steel, 900 tons, built by Messrs. D. & W. Henderson and Co., for Messrs. M. Langlands & Sons; "Saikio Mara," steel, 2800 tons gross, built by the London and Glasgow Shipbuilding and Engineering Company, for mail service in Japan; "Virginia," steel, 1800 tons, built by Messrs. Russell & Co., for Mr. Frederick Woods, London; Nos. 259 and 260, steel, screw steamers, built by Messrs. Simons and Co., for passenger service in the Mediterranean. Sailing vessels: "Olymp," steel, 1665 tons, built by Messrs. Chas. Connell & Co., Scotstown; "Moss Rose," three-masted schooner, 150 tons, built by the Ardrossan Shipbuilding Company. We append our usual statistical table:

MERCANTILE MARINE.

	Steamers. No.	Tonnage.	Sailing vessels. No.	Tonnage.
United Kingdom	4	14,000	1	150
Colonies	3	3,100	—	—
Belgium	1	1,250	—	—
Egypt	2	800	—	—
South America	1	750	—	—
Japan	1	2,800	—	—
Foreign (destination withheld)	2	500	1	1,665
March, 1888	14	25,000	2	1,815
March, 1887	16	11,697	4	7,500

COAL, IRON, AND COGNATE INDUSTRIES.

THE Board of Trade returns for the month of March and the first three months of the present year are now before us. The total value of the imports for the month shows a decrease of £204,109, as compared with March of last year, and of the exports an increase of £45,224. For the three months there is an increase of £4,589,039 in the imports, and of £2,557,450 in the exports, as compared with the corresponding period of 1887. The total quantity of iron and steel exported in March was 295,418 tons, a decline of 47,516 tons as compared with 1887, and an increase of 40,208 tons with 1886. For the quarter the total was 866,005 tons, valued at £6,173,312, a decrease in quantity of 27,428 tons, but an increase in value of £686,815, as compared with the first three months of last year, and an increase of 167,332 tons and £1,060,099 in value as compared with the corresponding period of the previous year. We append our usual tabular statement.

	Month of March. 1888. £	1887. £	Three months. 1888. £	1887. £
Pig and puddled	167,147	229,673	393,617	549,731
Bar, angle, &c.	144,775	123,458	415,385	325,030
Railroad	327,836	272,122	1,196,674	782,816
Cast and wrought	404,333	393,512	1,184,953	1,039,781
Hoops, sheets, &c.	343,253	246,211	962,942	692,469
Steel, unwrought	120,036	207,577	338,001	551,821
Tin plates	491,906	451,656	1,312,822	1,047,303
Unwrought copper	161,858	84,007	594,916	233,564
Coals	768,187	818,371	2,277,503	2,215,948

The above figures must, on the whole, be regarded as satisfactory proof of an improvement in our foreign trade. In the details of the returns there are one or two points which merit the attention of traders interested in the industries under review. We have frequently pointed out the probability of the iron masters of the United States finding themselves in a position to satisfy the bulk of the home requirements of that country, and the material falling off in our exports of crude metal, both iron and steel, is mainly due to the increasing independence of that market. On the other hand, it is gratifying to note that, recognising this situation, British traders have been able to more than balance the falling off in the demand for crude metal from the American Union by an appreciable increase in their exports of railroad and finished iron to other centres of consumption, amongst which may be mentioned India, Japan, and the Argentine Republic. The augmented value of the exports of unwrought copper is, of course, due to the action of the French syndicate with regard to prices, which have advanced more than 100 per cent. during the last few months. The maintenance of our export coal trade, in face of the keenest competition by Continental colliery proprietors, is a gratifying feature of the returns. In this connection it may be noticed that while the coal industry in England is being affected by the operation of the new Mines Regulation Act, in Germany also legislative enactments, dealing with mining, have recently passed into law; and now in France and Belgium as well we hear of proposals in the same direction.

Turning to the home markets, we can only describe a retrospect of the quarter as an unpleasant one, and the outlook for the immediate future as anything but satisfactory. The year opened with promises of a distinct revival in trade, and the January quarterly meetings at the different centres of the iron trade were noticeable for the firmness of makers at somewhat advanced prices. Those held a few days ago afford indications only of a retrograde movement. At Wolverhampton and Birmingham both pig iron and finished iron were unsaleable at anything above the lowest rates of 1887. In the North the price of Scotch warrants is 3s. below the opening prices of 1888, and during the past twelve months stocks of iron in Connal's stores at Glasgow have increased by nearly 110,000 tons. The price of Middlesbrough pig iron stands at about 32s. per ton. This condition of things is mainly due to the fact that the anticipated revival in trade, and the improved prices which obtained in January, called into activity a portion of the powers of supply which were then lying dormant. For instance, during the quarter there have been twelve additional blast furnaces blown in. The result is that, as the requirements of consumers expand, the productive capacity of the country likewise increases, and the adjustment of the relations of supply and demand is thereby retarded. While we conclude this article by using the words of one which we published in our issue of April 22nd, 1887, viz., that "so far as we have been able to judge, the condition of the iron trade is at this moment very nearly as bad as it was towards the close of last year," still encouragement may be gleaned from the consideration that the process just referred to is a necessary prelude to a stable revival in trade, as, before such a revival can occur, the requirements of consumption must overtake a normal power of supply, and this would certainly include a proportion of that now lying dormant.

ELECTRIC LIGHTING AT THE VICTORIA HOTEL, MANCHESTER.

THIS elaborately finished hotel has recently changed hands, and the Manchester Corporation as owners, in leasing the hotel to the present proprietors, arranged that the principal rooms and passages should be lighted by the electric light. As the building has for some time been provided with ample boiler power, the question of providing driving power for the dynamos was to some extent simplified. The electric light installation now erected is made up of two independent plants fixed in the basement, each plant being capable of supplying current for 250 16 c.p. lamps. Connected with each plant is a 12 h.p. Tangye vertical engine, fitted with improved continuous lubricating appliances, and driving a compound wound Crompton dynamo by means of a linked belt. The dynamos are arranged to run at 700 revolutions per minute, with the engine running at only moderate speed.

Distributed throughout the hotel are some 400 incandescent lamps; but the chief feature in connection with the lighting arrangements is in the large billiard room, where ten tables are electrically lighted, the incandescent lamps taking the place of the usual ring of burners placed over each table. The grill room and large dining hall are lighted by three-armed pendant fittings, suspended from the ceilings by flexible twin conductors. These fittings are of light design, and contrast very favourably with the existing heavy gaseliers. The switches, cut-outs, and terminal blocks from which the pendant fittings are suspended are all mounted on porcelain, with neat covers of the same material. The casing carrying the wires has been neatly fixed around and along the mouldings and cornices, and is hardly perceptible.

The contract for this work was placed in the hands of the Manchester Electric Supply Company, Limited, and has been carried out under the superintendence of Messrs. Holme & Vaudrey, the engineers to the company.

Books Received.

Reviews.

A HAND BOOK TO COTTON SPINNING. By J. E. Holme. Manchester and London: JOHN HEYWOOD.

This little book is intended to furnish the carding and spinning overlooker with a series of rules by which the calculations necessary for the various processes of spinning can be made. The rules are stated in plain language, and are supplemented by examples worked out so clearly and simply that no one possessing a rudimentary education need find a difficulty. In addition to these rules and examples the author gives brief descriptions of the various machines, with a number of hints as to their management which are eminently practical, and founded, no doubt, on personal experience. In dealing with the revolving flat carding engine, Mr. Holme has described a special machine, which is not the one in most general use, nor can it be taken as a leading type. This, we think, is a mistake, as it is always well in a work of this description to avoid specialisation, seeing that the aim is to give information which may be generally valuable. This, however, is the only adverse feature in a book which is likely to be of good service to cotton spinners. At the end of the book are a number of tables of useful character.

AMERICAN CHEMICAL JOURNAL. Vol. IX., Nos. 3 and 4 Edited by IRA REMSEN, Baltimore.

These two numbers of the ninth volume of the *American Chemical Journal* contain several papers of great interest to the theoretical chemist. The two papers by Professor A. Michael on the subject of allo isomerism deserve careful reading, as does also the reply to the former of the two papers by R. Anschütz, of Bonn, concerning the isomerism of fumaric and maleic acids. Professor Michael also contributes papers on "the action of phosphorus pentachloride on the ethers of organic acids, and on acetanilide." Two papers of importance to the analyst are: (1) A method for the determination of butter in milk, by H. N. Morse and W. M. Burton; and (2) The estimation of carbonic acid in beer, by Messrs. Crampton and Trescot, of the Laboratory of the United States Department of Agriculture. An improved form of Elliott's gas apparatus is described by J. B. Mackintosh, and the new pyrometer by E. H. Keiser is of simple construction, and likely to be found of general use in laboratories in which work at high temperatures is conducted.

ALL ABOUT OUR RAILWAYS. London: CARR & Co.

This is a small book published at a shilling, and is intended to convey a considerable amount of information about railways which is not to be found in ordinary guide books, and which at the same time is likely to be of use to those who require to travel much. As the editor remarks, there is a great dearth of railway literature of a nature likely to attract the public. Most of the existing volumes on the subject, though interesting enough to those who are intimately acquainted with railway work, are too ponderous for the million. Learned discussions on gradients, horse power, or tractive force, may give a thrill of enjoyment to the scientist; but the everyday reader is desirous of obtaining information concerning matters coming under his immediate notice. He is anxious, in a word, to glean anything interesting about the universal means of travel. Although the book scarcely justifies its claim to tell us *all* about railways, still it does tell a good deal which is not generally known, and will be found both useful and interesting by the large numbers whom either business or pleasure impel to travel.

THE MERCANTILE YEAR BOOK AND DIRECTORY OF EXPORTERS. 1888. Edited by Walter Lindley Jones. London: LINDLEY JONES & Co.

This is a little book, the scope of which is explained in the title. It commences with a street itinerary of the city of London, which gives the names of the firms of exporters to be found there, together with the class of goods shipped by them. A map of the city has been added to this year's issue in connection with this section. The second part contains information which is more valuable, because not otherwise so readily accessible, and gives a list of merchants and importers in the Colonies and abroad, with the names of their English representatives and buying agencies. A list of the classes of goods shipped from London, with the names of the shippers, and an alphabetical list of the merchant exporters of London, with their addresses and the markets with which they trade, are also given. What will be found of use by

Digitized by Google

exporters for reference is the fifth part of the work, which gives the tariffs in force in the British Colonies and possessions, and particulars of the services of some of the great ocean lines, in addition to miscellaneous information.

PATENTS CONVEYANCING: A COLLECTION OF PRECEDENTS IN CONVEYANCING LETTERS PATENT. By Robert Morris, M.A. London: STEVENS & SONS, 119, Chancery Lane.

Hitherto there has been no work of reference devoted exclusively to the sale and transfer of patents, to agreements for licenses, and to other transactions in relation to Letters Patent, and practitioners have been compelled to refer to precedents which have arisen in their own practice with such inadequate supplementary aid as they could obtain from "Prideaux." In such works as the one before us, one generally turns first to the table of contents and to the general index as a preliminary investigation of its value. To show how thoroughly and with what painstaking care this book has been produced, we may say that the text occupies 384 pages; the table of contents, thirteen pages; the table of cases cited in the text, nine pages; and the index, fifty-nine pages. In the arrangement of the work, the author has followed a simple system of classification of his subject which renders reference extremely easy. He commences with a dissertation on practice under the old and the existing Acts of Parliament relating to patents; this is followed by a chapter on agreements, in which the author discloses his authorities for the precedents which follow, and discusses their operation and effect. The precedents in this section, as in each of the others, consist of forms of recitals and clauses which are of common application, followed by a set of agreements. Together these meet all cases which have arisen within our experience, and we can scarcely imagine a case in which they could not be employed almost literally, by discriminating collation and application. The same may be said of the precedents included under the other headings. The precedents for assignments and mortgages of patents have likewise an explanatory chapter, as have also those relating to licenses. In each case the opinions and observations advanced are well supported by cases referred to in foot notes. There is appended to the book a reprint of the principal statutes having reference to the subject matter. Mr. Morris has approached his work systematically, and accomplished it so thoroughly as to leave little or no room for addition or improvement. Although intended primarily for the use of solicitors, very few of whom, unfortunately, have any practical acquaintance with patent law and practice, it cannot fail to be extremely valuable to inventors and manufacturers, if they will only bear in mind that they cannot safely act as their own lawyers by its guidance alone.

THE PROSPECTOR'S HAND BOOK. By J. W. Anderson, M.A., F.R.G.S. London: CROSBY LOCKWOOD & SON. 1888.

The third and enlarged edition of this hand book, which, as its title states, is a guide for the prospector and traveller in search of metal-bearing or other valuable minerals, contains a few important additions upon the previous issues. The author has traversed the mineral fields of New Zealand, New Caledonia, New Mexico, and Colorado, and has, therefore, practical experience as well as considerable theoretical knowledge of the subjects upon which he writes. The book is divided into short chapters upon the operations necessary for the opening up and discovering new mineral localities, and is not burdened with too much scientific padding of a geological or chemical nature. The second chapter, dealing with rocks, is short and much to the point, while another chapter later in the volume treats of the composition of the more important rocks which the prospector is likely to meet with. The chief metallic ores and minerals have two chapters devoted to their consideration, and brief rules for their detection are given, which are sufficient even for the inexperienced to form a comparatively accurate judgment of the value of any rock specimen he may meet with. We cannot say much in favour of Chapters VIII. and IX., which deal with testing by the wet process, and the assay of ores. The author, on page 9, while advising a prospector to be independent of the opinion of others, says that he should "never grudge a few shillings or dollars in obtaining the advice of a proper assayer." This is a sound doctrine, and we are of opinion that it is a mistake for the miner to attempt anything in the shape of an assay or chemical quantitative estimation of the value of his ores. Although many of the methods used in assaying are comparatively easy, yet good results can only be obtained by men experienced in their use, and attempts at such estimations by novices are liable to give misleading results. If the notes on gold, silver, lead, and copper assaying are viewed in this light, no harm will be done; but we think that any mention of graduated burettes and details of weighing, without proper explanations of a burette and a balance, are apt to confuse rather than enlighten the reader. Chapter X. on surveying is a good one, and covers the methods of solution of problems connected with adits, shafts, and lodes of a mine, and distances from inaccessible places. The book is throughout of a thoroughly practical nature, and can be confidently recommended to emigrants, prospectors, and travellers generally, as the information it contains can be thus quickly acquired before the real work of prospecting commences. A useful addition to the book would be a list of necessaries for the "outfit" of a prospector, including the apparatus and few chemicals required in preliminary testing by the blowpipe, &c., which are admirably given in the third chapter, as well as in the chapters devoted to the consideration of the characteristics and occurrence of metals and other ores.

IMPROVED AUTOMATIC LUBRICATOR.

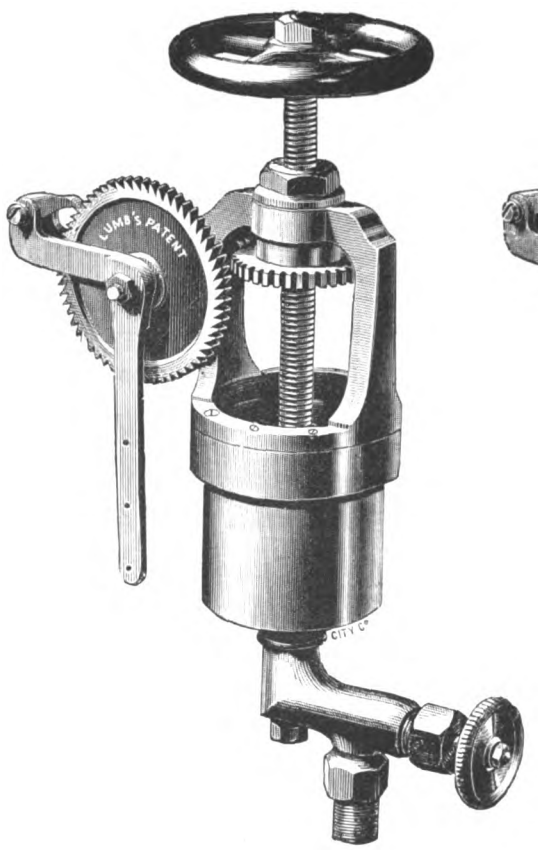

FIG. 1.

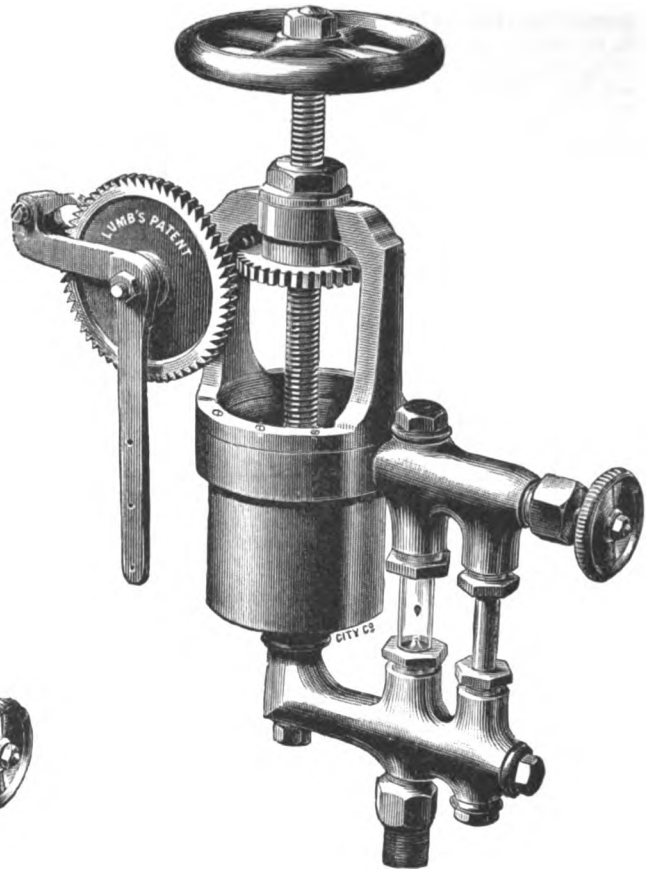

FIG. 2.

IMPROVED AUTOMATIC LUBRICATOR.

OUR illustrations show two forms of an improved automatic lubricator designed by Mr. J. Lumb, Perseverance Brass Works, Elland. Figs. 2 and 3 show the lubricator fitted with an arrangement by which the lubricant may be viewed as the piston is descending, Fig. 1 being intended for stiff and Fig. 2 for liquid lubricants. The lubricator works in the following manner: One end of the lever A, which is either bent or straight, is attached to a part of the machine which has a suitable motion. This lever carries a pawl B engaging with the ratchet wheel C. On the shaft carrying C the worm D is keyed, and gears with the worm wheel E, which is free to revolve, but is secured against sliding by a nut on the top of the frame. The boss of the worm wheel E is threaded, and serves as a nut for the screw F, which is connected to the piston P by a nut which is provided with a square hole G fitting upon the square part of the valve H. When starting the lubricator the piston P is raised by means of the hand wheel and the cylinder O filled with the lubricant, then P is lowered until it comes in contact with the lubricant and the pawl B is engaged with the rachet wheel. The lever A, swinging to and fro, actuates the ratchet wheel, thereby rotating the worm and worm wheel, and forcing the piston downwards. The lubricant is forced through the valve H, passes along I, ascends through the glass tube L, and then descends through the glass tube N to the part which is to be lubricated. The apparatus shown in Fig. 1 is constructed similar to Fig. 2, except that the glass tubes are omitted and the lubricant passes from H into I (Fig. 3), and from there to the parts to be lubricated. As soon as the piston P reaches the bottom of cylinder O the hand wheel on the top of spindle F comes in contact with the nut, thereby locking F and E together, so that the piston revolves with the worm wheel E. At the same time the square hole G engages with the square part of H, thereby rotating the valve on its seating. The amount of lubricant discharged at each

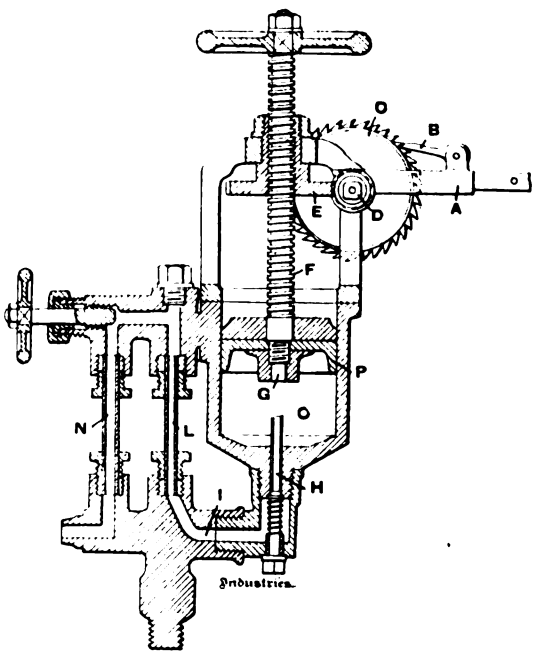

FIG. 3.

stroke of the lever is regulated by the number of teeth over which the pawl moves before engaging again. A larger amount of lubricant may be delivered at any time by turning the hand wheel on the spindle F. The advantages claimed for this lubricator are the following: It will work with any kind of lubricant, and does not depend on valves, taps, or condensation. It does not require any attention when starting or stopping the engine, can be fixed in any convenient position, the lubricant can be conveyed to the parts of the engine or machine by pipes, and the lubricator is not filled with water after the lubricant has been discharged. The maker claims that this lubricator will work against a pressure of 300lb. per square inch.

THE HEATING EFFECTS OF ELECTRIC CURRENTS.*

I HAVE taken a great deal of pains to verify the dimensions of the currents as detailed in my paper read on December 22nd, 1887, required to fuse different wires of such thicknesses that the law

$$C = ad^{3/2}$$

is strictly followed; and I submit the following as the final values of the constant "a" for the different metals:—

	Inches.	Centimetres.	Millimetres.
Copper	10,244	2,530	80·0
Aluminium	7,585	1,873	59·2
Platinum	5,172	1,277	40·4
German silver	5,230	1,292	40·8
Platinoid	4,750	1,173	37·1
Iron	3,148	777·4	24·6
Tin	1,642	405·5	12·8
Alloy (lead and tin 2 to 1)	1,318	325·5	10·3
Lead	1,379	340·6	10·8

With these constants I have calculated the two tables given above, which I hope will be found of some use and value.

* By W. H. Preece, F.R.S.

CENTRAL STATION LIGHTING.

(TRANSFORMERS *v.* ACCUMULATORS.)

AT a special meeting of the Society of Telegraph Engineers and Electricians, held on the 19th inst., the discussion was resumed on Mr. R. E. Crompton's paper on the above subject, an abstract of which was given in our last issue.

Mr. Preece, in continuing his speech commenced at the previous meeting, recapitulated the three principal arguments in favour of batteries, viz., the convenience of storage, the utilisation of the current for motor purposes, and the fact that a small plant could be used during the whole of the day. He then pointed out that on the other hand, there were also several arguments in favour of transformers, viz., that a higher e.m.f. can be employed, and therefore a smaller current in the distributing mains; that transformers are simple in construction and can be easily stored away in odd corners or, as Mr. Kapp suggested, below the pavement, and that no supervision is required; and that the efficiency of transformers is undoubtedly much higher than that of batteries. With reference to the load diagrams for electric lighting during the twenty-four hours, he pointed out that it was necessary, in any case, to provide energy for the period corresponding to the high points of the diagram, and that it did not matter much whether the capital was expended in the purchase of more batteries, or in providing additional engine power. Electric lighting on the transformer system had been successfully carried out by Messrs. Gaulard and Gibbs at the Grosvenor Gallery installation, which had been a pioneer for electric lighting in this country. The transformer system had also been used with favourable results at Eastbourne and Brighton, largely on the Continent, and to a still greater extent in the United States. With reference to Mr. Crompton's remarks as to the waste of steam in the secondary generator system, he considered this to be a question which concerned the engineering principle adopted, rather than bearing on the question whether transformers or accumulators should be used. The loss took place in the engine room and not in transforming. An important question, not raised by Mr. Crompton in his paper, was whether 30-watt 10 c.p. lamps or 60-watt 16 c.p. lamps should be employed. He himself was in favour of the smaller candle power lamps, which gave satisfaction in all cases where the others had not been previously supplied. Another question which should be considered was with regard to the best voltage to be employed. In this country, all kinds of potential differences were used indiscriminately in different installations; but there ought to be uniformity. In America, 50 volts had been generally adopted, and the lamp had a longer life owing to the filament being thicker. With regard to the relative economy of transformers and accumulators, consulting engineers had to base their advice on the nature of the district proposed to be lighted. A compact neighbourhood such as the City of London could best be served by the Hopkinson-Edison three-wire system; but this would not be the case with a scattered district like Wimbledon, where the mains may be ten or twelve miles long. After having referred to the accumulator installation now being carried out by Mr. J. H. Gordon at Whitehall, he stated that he still kept his mind open on the subject of secondary batteries; but, until success was assured, he would give his opinion at present in favour of secondary generators.

Sir David Salomons agreed with the figures relative to the cost of lighting by means of transformers, which Mr. Crompton had given. The efficiency of accumulators might fairly be estimated at about 70 per cent., and the durability was greater than is generally supposed. With regard to Mr. Preece's statement about the paste falling, his experience showed that there was not more than 1lb. lost after three or four years' use. He thought the 4 per cent. margin of potential difference allowed by Mr. Crompton much too high, and that 2 per cent. was more than enough unless the lamps were over-run. The working of central stations without accumulators was much the same as having gas works without a gasometer. At the same time, he believed that the first installation would not see a return of sixpence. In the load diagrams given by Mr. Crompton the curve would become more regular, as electromotors are certain to come into extensive use. To avoid the possibility of a breakdown, accumulators should be arranged with two or more sets in parallel. In his own experience there had been a case where, if one series only had been used, a breakdown would have resulted. He agreed with Mr. Kapp that it was very important to have an efficient system of regulation, a point which had not been mentioned by Mr. Crompton. Old accumulator cells could be renovated and made practically equal to new at the expense of about 1 per cent. of their original cost.

Mr. Crompton explained his method of regulation by attaching the leads to intermediate cells in each series, allowing the current to pass simply through the outside cells in parallel, without any energy being taken from them. A simple mechanical arrangement was used for adjustment, which was at present performed by hand, and which could easily be rendered automatic if desired. This had been used at the Vienna installation for ten months, and also at the central station at Kensington Court, and no hitch whatever had occurred.

Mr. Swinburne referred to the practicability of employing alternating current machines in parallel, and stated that it all depended upon the kind of machine employed. He described a method which he had devised for automatically stopping machines which get out of step. The only objection to the use of alternating currents for driving motors was that the motor would have to be very large. Alternate current machines could be made to run at low speeds, and cheaper than direct current machines.

General Webber criticised Mr. Crompton's proposal to lay down bare copper conductors, suspended by insulators from the roofs of subways, with a cross section of two superficial feet. Such subways could not be made water tight. At first there would not be much difficulty; but within a couple of years the conductors and insulation would be completely destroyed, as the subways would leak, and would also very soon be tenanted by rats. The conductor could not be got at without taking up the roadway. He pointed out that no difficulty had been experienced in raising capital for the London Hydraulic Company, whose system was a far more costly means of distributing energy than by means of electricity, and he expected that there would be a large increase in the demand for electrical distribution of energy. Mr. Crompton's allowance of 20 yards of main lead for each house was excessive, 17 yards being amply sufficient in the case of a district with wide streets and long frontages. The use of bitumen concrete casing for underground conductors was, from his own experience, found to be very satisfactory, and could be employed in the City, where such a subway as Mr. Crompton's could not be laid down.

Mr. Sydney Walker pointed out that the apparatus to which they must look for progress, more than either to transformers or batteries, was the lamp, as a 200-volt lamp would greatly reduce the cost of copper. A cheap and more efficient lamp would largely assist in the development of central station lighting. The increased cost of providing durable insulation for dynamos and for mains with high potential currents, more than counterbalanced the advantages attending the use of transformers; and an absolutely efficient service could be obtained with accumulators.

Mr. Hammond vigorously repudiated Mr. Crompton's statement that the Brighton and Eastbourne installations were only of a temporary character. The installation at Eastbourne had been running for six or seven years, and the distribution there was not by means of overhead wires, as had been stated. At present they had to be contented with doing scattered lighting, and the transformer system was found to be undoubtedly the most suitable, and there was no difficulty in having the load just proportionate to the current required. With regard to the theory that the battery system was preferable on account of there being a reserve of force, the same was the case in the transformer system, as a spare engine was always in readiness in case of a breakdown, and an engine was

Digitized by Google

hardly likely to suddenly stop without warning. He had some accumulators in use at Brighton, and these formed the only portion of the system of which they were at all afraid. They were by no means equal to the theoretical efficiency, as only 60 per cent. could be obtained, whilst their Eastbourne transformers gave an efficiency of 95 per cent. He considered 10 per cent. far too high an allowance for the depreciation of transformers which were of very simple construction, and had no moving parts; in fact, such an allowance was even too high for dynamos. On the other hand, Mr. Crompton's allowance of 15 per cent. for depreciation of accumulators was too low.

Mr. Trotter thought that until makers of accumulators were prepared to guarantee to keep them in order for a fixed annual payment few persons would care to risk the expense. He considered Mr. Crompton's assumption that two houses out of three would require the electric light, was too sanguine for some years to come, and that two out of ten was a much more reasonable estimate, and this told greatly in favour of the use of transformers. Some prejudice had been caused owing to the want of a spare engine at full load, and the example of water works should be followed, which always had a reserve of power in case of accident.

Notes.

THE ARCHITECTS' REGISTRATION BILL.

This Bill, which we have had occasion to criticise rather severely, was withdrawn on its second reading; but not before the promoters had shown their utter ignorance of the subject with which they were dealing. The Bill was opposed by the Attorney General, Mr. Giles, Sir Lyon Playfair, and others, and scarcely anybody had a word to say in its favour. We need not enter into the details of the debate, but we recommend them to the attention of those who believe in Acts of Parliament rather than in voluntary association and co-operation.

BOILER EXPLOSION AT BILSTON.

About five a.m. on Saturday last, a boiler exploded at the Capponfield Blast Furnaces, Ladymoor, Bilston, belonging to Messrs. Thomas & Isaac Bradley. The boiler, which was made of iron, was of the plain cylindrical externally fired type, 40ft. in length, and 7ft. 6in. diam., forming one of a battery of six, heated by gas from two blast furnaces, and were worked at about 23lb. per square inch. Upon examination it was found that a seam about 14ft. from the back end had ripped through the rivet holes, the fracture extending into the solid plate, but causing little damage beyond unseating the boiler, and scattering the brick work. No person was injured. From the appearance of the plates, the cause of the explosion would appear to be shortness of water, due to neglect of the feed supply.

ADULTERATION OF OLIVE OIL.

M. R. Brullé has made a number of experiments on the methods of detecting the presence of adulterating oils in olive oil, and has finally adopted the following process: To ·1 grain of dried white of egg powder 2 cub. cms. of nitric acid, and 10 cub. cms. of the oil are added, and the mixture is gently heated for some time. When the acid begins to boil the tube is inclined to cause the two liquids to react more completely. A greenish yellow colour indicates a pure olive oil; but if any other oil be present a brown amber tint will be produced, which is the more intense the greater the amount of adulteration. Colza, rape seed, cotton, and linseed oils all respond to this test, and the only exception which has been observed is the oil known in commerce under the name of exotic aveline, which gives a pink colour under these conditions. When the quantity of the adulterant present is less than 5 per cent., it is advisable to adopt the bromine method on the saponified oils devised by M. A. Levallois.

THE ENLARGEMENT OF THE SUEZ CANAL.

The International Commission on the Suez Canal, which assembled in 1885, made the following recommendation, which was accepted by the Canal Company: Between Port Said and the Bitter Lakes, the straight portions of the Canal are to be ultimately widened to 65 metres (213ft.) instead of 22 metres (72ft.) as at present. The widths at the apex of the curves of large radius in this part of the Canal are to be 75 metres (246ft.), and in the curves of small radius 80 metres (262ft.); these to be adopted instead of the normal width of 22 metres existing in 1885, when the report of the Commission was made. In the straight portions between the Bitter Lakes and Suez the Canal is to be ultimately widened to 75 metres, and in the curves the width is eventually to be 80 metres, all these widths being measured at the level of 8 metres below low water, that being the bottom of the Canal in 1885. As regards the deepening, the recommendation of the Commission, also accepted by the company, was that the Canal should be deepened from 8 metres (26ft.) below low water of ordinary spring tides to 8½ metres (nearly 28ft.) at the first, and to 9 metres (29½ft.) eventually. Mr. John Coode, of 5, Westminster Chambers, who was a member of the Commission referred to, states that he has good authority for stating that the first instalment of the deepening—viz., to 8½ metres—is expected to be completed for fully one-half the length of the Canal by the end of the present year, and that the entire length will be deepened to that extent by the middle of 1889.

DISINFECTION ON THE MISSISSIPPI.

Very careful precautions are adopted by the authorities to insure the disinfection of vessels entering the Mississippi from doubtful ports. Every accessible surface, except that of the cargo, is first sprayed with an aqueous solution of chloride of mercury (1 in 1000), the quantity used for a single vessel varying from 1500 to 3000 gallons of the solution. The hold is disinfected by burning roll sulphur in a battery of eighteen furnaces contained in a specially built tug, the gas being forced into the vessel by means of a powerful fan. By this method air rich in sulphurous acid is introduced into the hold at the rate of 180,000 cub. ft. per hour, and as much as 100lb. to 700lb. of roll sulphur is burnt for the disinfection of each vessel. Lastly, all wearing apparel and hangings are submitted to the action of moist steam at a temperature of not less than 230°F.

NEW PHOTOGRAPHIC SUNSHINE RECORDER.

At the last meeting of the Royal Meteorological Society, Mr. J. B. Jordan read a paper on the subject of his new pattern photographic sunshine recorder, in which he stated that the improvement over the previous pattern consists in using two semi-cylindrical or D shaped boxes, one to contain the morning and the other the afternoon chart. An aperture for admitting the beam of sunlight is placed in the centre of the rectangular side of each box, so that the length of the beam within the chamber is the radius of the cylindrical surface on which it is projected; its path, therefore, follows a straight line on the chart at all seasons of the year. The semi-cylinders are placed with their faces at an angle of 60° to each other. They are fixed on a flat triangular plate, which is hinged to a stand having levelling screws attached, and fitted with a graduated arc as a means of readily adjusting and fixing the cylinders to the proper vertical angle agreeing with the latitude of the station where used.

SEARCH LIGHTS WITH AUTOMATIC FEED.

Search lights for naval purposes have hitherto generally been made with hand feeding gear consisting of two screws, that actuating the positive carbon having twice the pitch of the other, while the focussing was effected by a separate screw. This type of lamp is extensively used in our own navy; but as it requires one of the men to constantly watch the arc, several attempts have been made by the manufacturers of arc lamps to produce automatic feed gear for search lights. These find favour in some foreign navies, and Messrs. J. G. Statter & Co., Limited, of West Drayton, have now in hand for the Dutch navy four projector arc lamps each for a current of 100 ampères, and self feeding. The carbons are 30mm. in diameter, and the feeding mechanism is similar to that of their ordinary type of arc lamp, with hand screw for focussing the arc. Two projectors are supplied with these lamps, with Chance silvered mirrors supported in elastic brackets, so as to protect the mirrors from concussion when the guns are fired. In addition to the mirror, the lanterns are fitted with divergers to fantail the light. The diverger when in use is put before the plate glass front, but can be swung back if a solid beam of light is required.

THE USES OF THE RAMIE PLANT.

In *Industries*, Vol. IV., page 383, we gave a note on the American experiences with ramie fibre. In Spain more advance appears to have been made in utilising it, and owing to many inquiries regarding the ramie plant having been received from England, Consul Woolridge, of Barcelona, gives some particulars as to the industries in which this plant can be employed, his information being derived from Señor Francisco Obiols, professor of agriculture in Barcelona. It is stated that the qualities of the plant are almost similar to those of flax, hemp, and jute. The resistance and durability of the fibre are much greater than those of jute, and it can therefore be advantageously employed for sacking. Its fineness and solidity make it also suitable for the manufacture of handkerchiefs and muslins. Compared with flax and hemp, the same weight of ramie will make about twice the number of yards of cloth, and it is at the same time less liable to rot when exposed to moisture. Ramie cannot be substituted for cotton, but it is suggested that it may be used in combination with it. It also cannot be used as a substitute for wool, owing to its being cool and light. The combination of ramie and silk is recommended instead of the common mixture of silk and cotton, as the tissues are more durable, and the gloss more lasting. It is specially suitable for sewing thread. There is no difficulty in colouring ramie, the best dies being indigo for blue, saffron for rose, the castor oil plant for orange brown, and turmeric for yellow. Señor Obiols states that the ramie is the most valuable fibre which industry can desire, as it can form threads to imitate cotton perfectly well, with the advantage of being of greater strength and duration; that all kinds of linen can be made from it, stuffs for trousers, shirts, and cloaks, sails for ships, sackcloths, cords, &c., as well as lawn and fine lace, which are much superior to those made of flax and hemp. He is of opinion that in a short time the ramie cultivation and industry will become the centre of a great industry in Spain.

THE BOARD OF TRADE RETURNS.

The returns for the month of March are on the whole fair, especially as there was some interruption of business owing to the commencement of the Easter holidays at the close of the month. The exports amount to £19,047,307, as compared with £19,002,083 in March, 1887, being an increase of ·2 per cent. Iron and steel shows a decrease in quantity of nearly 14 per cent., but an increase in value of about 1 per cent. The smaller quantity is mainly due to a decrease in the shipments of pig iron, old iron, and wrought steel, as most of the manufactured kinds, including railway materials, have made progress. Hardware and cutlery have slightly improved. The exports of copper have greatly decreased. The returns under the heading of machinery and mill work have increased 9 per cent. in value. Cotton goods are little altered, but in woollens the exports to France and Italy show a slight decrease. The imports amount to £32,590,821, as compared with £32,794,934 in March, 1887, a decrease of ·6 per cent. Raw cotton and cereals have decreased considerably. The imports of copper ore and regulus show an increase in quantity of about 76 per cent., and in value of 172 per cent.

PRIVATE FIRMS v. GOVERNMENT ESTABLISHMENTS.

At a time when our own military manufacturing departments have undergone such a thorough re-organisation, there may be interest in the following remarks, lately made in the Military Institution of the United States, on the occasion of the discussion of Captain Birnie's excellent paper on "Gun Making." Major J. B. Campbell, of the 4th Artillery, said that Captain Birnie doubted the advisability of taking the direction of military manufacture out of the hands of specially trained officers, and hoped that at all events the question, what guns the army shall use, will be entrusted to military men. If, by military men, he meant those who would have to use the guns, he would have a large following; not so, if the term is construed to mean the non-combatant corps of designers, constructors, and inspectors, that have heretofore controlled this question. Looking abroad, all great progress has been made in countries that have no national foundries and gun shops, and no exclusive corps of ordnance designers and manufacturers. Such nations were the first to be benefited by the ingenuity and skill of private manufacturers. In England, Whitworth and Elswick occupy the attention of the world rather than Woolwich, which latter has been successively driven from almost every one of its assumed positions by the superior practice and productions of other establishments. Germany, as well as some other nations, rely upon Krupp and Grusen; and France, recognising too late that the national shops and foundries of Gavre, Bourges, Ruelle, and Nevers were a poor reliance at the supreme moment, has called to her aid the emulation and progress of St. Etienne, Creusot, and St. Chamond. Austria, after years of official failure, has followed the example of Italy, and now gets her armament where it can be best and most cheaply made. In Russia alone Government establishments appear to prosper. This may be due to personal and despotic government; but as a rule the work is mere imitation, for rarely, if ever, are original conceptions produced by public functionaries. Government should never be a manufacturer or enter into any other kind of business, as in competition with private enterprise it falls behind and becomes extravagant. The vitality and progress inspired by successful competition, and supported by the acumen necessary to avoid the expense of failure, cannot be expected of those whose existence is equally comfortable in failure or success. Let the Government officers select the best gun suited for the purposes desired, or invent it if they can, inspect the material of which it is to be made, or even superintend the work of construction and test it when completed; but let the American manufacturer make it.

Patent Record.

Compiled from "The Official Journal of the Patent Office," by W. E. Heys, *70, Market-street, Manchester.*

APPLICATIONS FOR PATENTS.

(The names in italics within parentheses are those of Communicators of Inventions.)

ENGINEERING.

13th April, 1888.

5474. Newsome, A. ..... Hoists.
5485. Jackson, A., & others ... Heating water.
5486. Cadle, C. ..... Turbine water wheels (*Ridgway*).
5496. Williamson, J. ..... Steam boiler furnaces.
5501. Butterfield, F. ..... Apparatus for grinding rolls.
5503. Moseley, J. ..... Body blocks for railway and tramway vehicles.
5504. Passman & Wake ..... Vertical steam boilers.
5505. Helm & Bridge ..... Looms.
5511. Woolley, T. ..... Coating iron ships.
5512. Pohl, O. E. ..... Submerged reciprocating propellers.
5513. Pohl, O. E. ..... Steam cylinders and equilibrium valves.
5514. Hadden & Weldon ..... Car couplings.
5519. Blessley, W. H. ..... Pulleys.
5520. Smith, G. ..... Inlaying metal.
5525. Hall, W. H. ..... Horizontal feathering wind motor
5526. Hall, W. H. ..... Feathering paddle propeller for navigable vessels.
5527. Le Las & Robin ..... Supplying furnace fires with moistened air.

14th April, 1888.

5533. Scott, P. ..... Air propellers.
5538. Noton, W. ..... Separating and cleaning cotton.
5544. Leane, G. H. ..... Buckled plates.
5546. Mackenzie & Wake ... Riveting, punching, and shearing machinery.
5550. McNab, A. ..... Bleaching and washing textile fabrics and yarn.
5554. Wood, R. ..... Apparatus for covering wire.
5556–7. Smith, J. W. ..... Locomotive engines.
5558. Collins, B. A. ..... Torpedo boats.
5559. Corssen, G. A. ..... Torpedo nets.
5560. Elwell, T. ..... Steam boilers.
5563. Dehaitre, F. ..... Apparatus for hot pressing fabrics.
5566. Russell & Cooper ..... Machines for building anchors.
5570. Innes, J. ..... Machine for sawing barrel hoops (*Ballew*).
5571. Innes, J. ..... Machine for setting saws (*Ballew*)
5572. Methley, R. A. ..... Appliance for preventing locomotive drivers over-running danger signals.
5573. Vine, J., & others. ..... Machine gun.
5576. Boult, A. J. ..... Scouring woollen fabric (*Alexandre et fils*).
5578. Bass, T. ..... Ratchet braces.
5581. Delanne, G. ..... Steam and gas engines.
5582. Schurr, A. E. ..... Blast pipes for locomotives (*Swinerd*).
5584. Bain, W. P. ..... Feathering paddle wheel.
5585. Bonvillain & Guyon ... Hydraulic apparatus for baling cotton.

16th April, 1888.

5592. Douglas, G. C. ..... Singeing machines for textile fabrics (*Cargill*).
5596. Maxwell, J. ..... Steam engines.
5597. Dorman, W. H. ..... Circular knitting machines.
5599. Taylor & Taylor ..... Railway chair.
5602. Bedford, C. ..... Looms.
5603. Boxall, S. ..... Fish plates.
5605. Bond, B. R. ..... Blocking and rolling machine.
5607. Schnee, G. H. ..... Repeating mechanism for fire arms.
5609. Richardson, F. A. ..... Spring motor.
5611. Hopkinson & Hopkinson Washing machines.
5614. Ainsworth & Catlow Looms.
5617. Barker, G. ..... Girders.
5622. Richards, F. H. ..... Button setting machines.
5627. Carmichael, J. D. ..... Utilisation of the exhaust steam of engines (*Petrini*).
5628. Tavernier & Casper ... Gas engines.
5630. Ewing, W. J. ..... Rolling stock for railways.
5632. Humes, R. ..... Hydrocarbon engines.
5936. Dynes, W. ..... Seed shelling machine.
5639. Hart, S. ..... Carriages.
5641. Mauser, P. ..... Breech loading fire arms.

17th April, 1888.

5644. Allison, H. J. ..... Apparatus for casting ordnance (*Gatling*).
5648. Scott & Scott ..... Cutting pile fabrics.
5661. Küchen, A. ..... Parallel vices.
5665. Evans, W. ..... Blast furnaces.
5670. Rankine, J. ..... Feed supply of boilers.
5672. Paulson, R. ..... Breech loading and repeating fire arms.
5676. Williams, H. A. ..... Cold rolling metallic rods.
5684. Nicholas & Fanshawe .. Magazine fire arms and ordnance.
5691. Shackleton, E. ..... Machinery for spinning & twisting fibres.
5692. Charlesworth and Booth ..... Stripping the doffers of scribblers and clearers.
5693. Moore, E. ..... Maclines for ironing and calendering.
5698. Fontenilles, J. M. E. ... Pneumatic machines.
5700. Edwards, E. ..... Polishing metal surfaces (*Vercaeren*).
5701. Edwards, E. ..... Apparatus for weaving bags (*Sanz and Echeverria*).
5702. Rutty, G. G. ..... Ramming stone paving.
5709. Mauser, P. ..... Cartridge expellers.
5712. Ellis & Sturla ..... Numbering machines.
5714. Hunter & Hunter ... Cartridge loading machine.
5717. Dillon & Doyle ..... Moulds for casting metals.
5719. Wells & Weber ..... Hot air motors.
5720. Cowburn, T., & others . Continuous brake apparatus.
5724. Abel, C. D. ..... Petroleum engines (*Gas Motoren Fabrik Deutz*).
5730. Cunliffe, W. ..... Sewing machines.
5733. Plunkett, E. W. ..... Permanent way of railways.
5736. Hogg & Hogg ..... Spindles for spinning machines.
5737. Unbehend, J. J. ..... Machines for slotting rivets.
5739. Gould, C. E. ..... Rolled metal articles.
5741. Lake, H. H. ..... Metal lattice work (*Golding*).
5742. Gaggino, G. ..... Navigable balloons.
5743. Nordenfelt, T. ..... Breech mechanism for guns.

18th April, 1888.

5752. Russell, G. ..... Hydraulic motors.
5759. Russell, G. ..... Hoisting shears.
5761. Birch, W. ..... Machines for washing and dyeing woven fabrics.
5769. Dickinson, H. ..... Testing the strength of yarn.
5774. Rowden, W. T. ..... Gas motors.
5775. Carruthers, J. H. ..... Pumps.
5776. Heppenstall, B. ..... Looms.
5777. Bélicard, J. P. ..... Looms for weaving pile fabrics.
5778. Carter & Whiting ..... Repeater small arms.
5788. Mudd, T. ..... Supplying feed water to boilers.
5792. Chandler, N. ..... Steam engines.
5795. Dickie, M. ..... Looms.
5797. Gibert, F. ..... Paddle wheel.
5800. Walford, E. J. ..... Raising sunken vessels.
5802. Redfern, G. F. ..... Water gauges for steam boilers (*Barclay*).
5810. Gostling, W. A. K. ..... Slide rest for rose engine turning.

19th April, 1888.

5812. Shackleton, R. ..... Superheating steam.
5815. Parkinson, J. ..... Drilling machines.
5816. Norton & Hellewell .. Beating pile fabrics.
5824. Tyrie, W. C. ..... Hoists.
5826. Holt, J., & others ..... Stop motion and picker check, and apparatus for guiding and actuating healds.
5828. Green & Douglas ..... Printing and dyeing cambric.
5829. Fairclough, W. ..... Removing impurities from boilers.
5832. Lumb & Holt ..... Hoists.
5838. Fuller, H. J. ..... Sewing machines.
5840. Henderson, A. C. ..... Motive power machine (*Couchemann*).
5846. Fletcher, T. W. ..... Knitted warp fabrics.
5850. Livingstone, J. ..... Securing of the rails of railways.
5859. Gutensohn, A. ..... Coating metal plates with tin.

ELECTRICITY.

13th April, 1888.

5522. Segnitz, A. H. G. ..... Telephonic apparatus (*Brand*).
5528. Hermite, E., & others ... Voltaic batteries.
5529. Merry, P. G. ..... Reflector for incandescent electric lamps.
5531. Statter, J. G. ..... Electric lighting.

14th April, 1888.

5586. Lake, H. H. ..... Electric incandescent lamps (*Grivolas*).

16th April, 1888.

5640. Edmunds, H. ..... Distributing electricity.

17th April, 1888.

5681. Snell, C. S. ..... Electrical switches.
5704. Raworth, J. S. ..... Switch boards.
5708. Lea & Julian ..... Dynamo-electric machines.
5713. Hallock & Blickensderfer ..... Electric elevators.
5723. Webster, W. ..... Production of chalybeate waters by electrolytic action.
5731–2. Lake, H. H. ..... Measuring electric currents (*Thomson*).

18th April, 1888.

5745. Gillam, S. H. ..... Making electrical contacts.
5753. Huck, G. ..... Long distance telephone and transmitter.
5764. Randall, C. A. ..... Electromotor velocipedes.
5782. Mountain, W. C. ..... Electric arc lamps.
5783. Mountain, W. C. ..... Electrical transformers.
5786. Cashel, G. ..... Telephones.

19th April, 1888.

5811. Crompton & Swinburne Generation and distribution of electrical power.
5831. Schönherr-Schöner, T. Electric batteries.

CHEMISTRY.

13th April, 1888.

5484. Dawson & Hirsch ..... Alpha naphtylamine monosulpho acid.
5515. Deacon & Hurter ..... Manufacture of chlorine.

14th April, 1888.

5543. Knecht & Rawson ..... Mordanting wool with chromium compounds.

16th April, 1888.

5600. Parnell & Simpson ... Production of sulphuretted hydrogen.
5612. Gerdes, W. ..... Production of spirit.
5613. Rödiger, W. ..... Manufacture of soap.

17th April, 1888.

5673. Cheswright. C. ..... Separation of alloys.
5740. Lake, H. H. ..... Calcination of lead ores (*Bair*).

18th April, 1888.

5762. d'Andria, M. N. ..... Ammonia salts.
5781. Pass, E. de ..... Azo colouring matters (*Ewer and Pick*).
5790. Steinach, H. ..... Non-metallic porous bodies for electro-metallurgic deposits.
5794. Clowes & Briant ..... Manufacture of soap.

19th April, 1888.

5832. Pitt, S. ..... Colouring matters (*Cassella & Co.*)
5856. Castner, H. Y. ..... Sodium and potassium.
5857. Castner, H. Y. ..... Anhydrous aluminium chlorides.
5858. Castner, H. Y. ..... Reduction of aluminium.

MISCELLANEOUS.

13th April, 1888.

5476. Bennett, T. ..... Rifle sight verniers.
5482. The Worcester Royal Porcelain Company and Ranford ..... Decorating pottery.
5483. Harrison, J. ..... Compressing hay.
5488. Wythes, F. J. ..... Manufacture of castor bowls.
5489. McNeil, C. ..... Manholes.
5490. Crowden & Brown ..... Tricycles.
5491. Crowden & Brown ..... Jointing for tubular frame work.
5493. Harvie, W. ..... Search lights.
5494. Thomson, D. E. ..... Feeding pulverised substances.
5499. Lowe, W. ..... Adjusting the capacity of earthenware.
5506. James, J. W. ..... Rust proof knitting pins.
5508. Hunter, A. T. ..... Burning liquid fuel (*Stewart*).
5517. Edwards, E. ..... Presses for hay (*Zur Lippe*).
5518. Lenders, F. H. ..... Lamps (*Van Gael*).
5524. Bouverie & Balch ..... Pyrotechnic signals.

14th April, 1888.

5541. Dorman, W. H. ..... Screwed wire.
5548. English, R. A. ..... Condensation gutters.
5553. Hill, C. A. ..... Machine for cutting button holes.
5561. Johns, T. H. ..... Bottles (*Johns*).
5564. Wolf & Friemann ..... Miners' lamps.
5568. Innes, J. ..... Guide for machines for sawing hoops (*Ballew*).
5569. Innes, J. ..... Removing gum from saws (*Ballew*).
5577. Thompson, W. P. ..... Waterproof material (*Rave*).
5580. Hummelinck, C. H. ..... Closing of tins.

16th April, 1888.

5587. Gould, H. I. ..... Bottles.
5588. Deeley & Tombs ..... Manufacturing brass knobs.
5591. Low, R. ..... Gun projectiles.
5595. Kochs, W. E. ..... Cleaning and dusting tin plates.
5601. McCulloch, F. ..... Soldering irons.
5604. Frost & Houghton ..... Taps.
5620. Willis & Willis ..... Manufacture of enamelled earthenware.
5623. Sugg, D. W. ..... Gas lamps.
5624. McEvoy, C. A. ..... Fuses.
5625. Accles, J. G. ..... Cartridge boxes.
5626. Woodruff, H. ..... Conical springs.
5633. Piper, J. H. ..... Nuts and nut locks.
5634. Bates & Bates ..... Grain mixers.
5635. Bariquand, L. F. J., and others ..... Shearing instruments.

17th April, 1888.

5645. Whitehall, E. W. ..... Finishing hosiery.
5650. Comyn, F. ..... Net for beam trawling.
5657. Leigh, H. ..... Baling press.
5659. Hoyle, J. ..... Humidifying the air in mills.
5660. Murray & Cathcart ... Moulding clay.
5662. Weir, M. A. ..... Driving gear for bicycles.
5663. Koss, W. ..... Valves.
5669. Thompson & Daines .... Paring knives.
5677. Johnson, J. Y. ..... Expansion spool for paper rolls (*Taylor, Wickens, & Watt*).
5685. Nicholas & Fanshawe Cartridges.
5686. Nicholas & Fanshawe Explosives.
5689. Swallow & Proctor ... Artificial fuel.
5703. Newton, P. A. ..... Watches (*Ansonia Clock Co.*).
5710. Mitchell, W. E. ..... Double ball valve.
5711. Hine, F. A. ..... Eliminators.
5715. Jensen, P. ..... Belting (*Shieren & Brock*).
5722. Imray, O. ..... Bunsen burners (*Von Welsbach*).
5728. Elphick, O. ..... Water waste preventers.
5735. Lake, H. H. ..... Separating grease from steam (*Lowden*).
5738. Lake, H. H. ..... Apparatus for indicating the pressure of liquids (*Herschel*).

18th April, 1888.

5751. Wybill, J. ..... Portable field armour.
5757. Claremont, E. A. ..... Fire alarms.
5765. Kenworthy, J. T. ..... Self registering lock.
5766. Hubert, J. H. ..... Velocipedes.
5767. Snell & Pearce ..... Hurricane lamps.
5770. Townsend & Thompson Adjustable telescopic standards.
5779. Warner & Warner ... Lace patterns in hosiery.
5787. Bannister, M. C. ..... Paints and varnishes for iron, wood, stone, or cement work.
5798. Needham, J. ..... Bicycles.
5803. Nash & Bond ..... Hanger for lamps.
5805. Hiller, G. ..... Apparatus for cutting cord.
5806. Cooper, R., & others ... Filter.
5808. Ponton, A. C. ..... Manufacture of artificial stone.
5809. Appleton, J. F. ..... Bottle.

19th April, 1888.

5813. Clough, T. ..... Manufacture of boots.
5821. Burt & Edmonds ..... Lanterns.

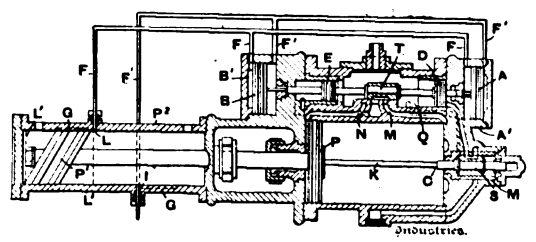
ABSTRACTS OF BRITISH PATENT SPECIFICATIONS.

Compiled from the Published Specifications by W. E. Heys, 70, *Market-street, Manchester.*



ENGINEERING.

Submarine Vessels.—*G. Poore & W. C. Storey, London.*—The objects of this invention are to maintain the vessel in a horizontal position when submerged, to enable the vessel to rise or sink with an even keel, and to raise the vessel by automatic means in the event of her reaching a greater depth than is compatible with safety. In attaining the first object two chambers B are arranged open to the external water. The pistons C are connected by the rods E, levers F H, and chain H^1 to the arm I of the double bell crank lever, whose other arms J are connected to the valves D. When one of the ends of the vessel is lower than the other owing to the displacement of bodies inside the vessel, the difference of pressure on the pistons C will automatically operate one or other of the valves D. The two ports of the cylinders K^1 L are connected by the pipes L^1 with the exterior water and with the pipes K. The valves D are three-way cocks, and communicate with the tank O by

means of the pipes N^1. The water in O is kept at high pressure by means of the pump J^1, and when one of the valves D is operated the water rushes through it into the pipes K, and the water from outside is admitted to one or other of the cylinders L, and so the balance of the vessel is restored. In order to enable the vessel to rise on an even keel, the piston O^1 is connected to the graduated lever P^1, and also by the lever I J to the valves D. By altering the position of the weight Q, the specific gravity of the vessel may be varied, and the vessel raised or lowered. In carrying out the third part of the invention, the cylinder S is fitted in the upper side of the vessel, and the piston T is connected to the lever V W. This lever works a valve which controls the passage of the fluid in X. The position of the piston T will vary with the depth of the vessel, and when the pressure becomes too great the valve is opened, and the water from a steam boiler is allowed to escape into the exterior water, and thus reduce the ballast. Four claims are made for these different improvements.—No. 4227. March 21st, 1887. 8*d*.

Pumping Engines.—*L. Soulerin, Paris.*—The main object of this invention is to effect the cut-off of the steam by means of the compressed air, or by means of the liquid which is being raised by the engine. The accompanying figure illustrates the mechanism employed. Two differential pistons D E are connected by a rod to the main slide valve T. One side of the piston E is in permanent connection with the exhaust, whilst the opposite face of D is made to communicate with the live steam or the exhaust, according to the position of the valve S in the chamber M. The chamber M is continually in communication with the valve chest through the passage indicated by the dotted lines. The ends of the rod connecting D E extend through stuffing boxes, and are made hollow so as to act as guides to the rods of the two pistons A and B. The opposite faces of these latter pistons communicate alternately by the pipes F F^1 with the

delivery side of a water cylinder P^2. The piston P^1 is inclined to the axis of its rod. When live steam is admitted into the valve chest it acts upon the larger piston D, and causes the rod and slide valve to move so as to admit the steam through the port N into the steam cylinder behind the piston P. At the commencement of the forward stroke the water pressure in the cylinders A^1 B^1 will be equal on both sides; but as the piston P^1 moves and brings the space at its back into communication with the space at the left side of the pistons A B, the pressure on the backs of these pistons will be reduced, and consequently they will be caused to travel in the reverse direction; the slide valve will thus begin to cover the steam inlet port N, while the exhaust passage from the front of P will remain open, and the piston P will complete its stroke by the expansive power of the steam. When P is about to complete its forward stroke it comes into contact with the shoulder C on the spindle of S; the valve S is thus opened to admit steam to act on the larger piston D, and the slide valve is consequently reversed in position. The port M^1 is opened to steam and the port N to exhaust, and the motion of the engine is reversed. The return stroke is conducted on similar lines to the forward stroke. Eleven claims are made for this method of working the slide valve.—No. 5775. April 20th, 1887. 11*d*.

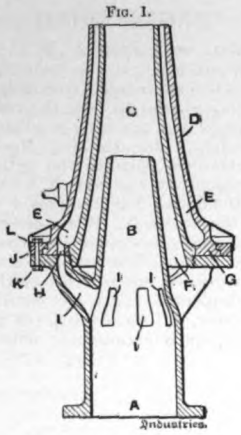
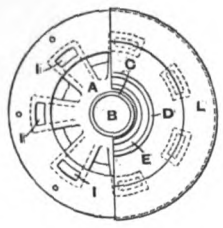
Blast Pipes for Locomotives.—*H. Appleby & J. G. Robinson, Limerick.*—The parts of this apparatus are arranged in such a manner as will allow the blast to be varied at will. The improved blast pipe A consists of a central steam nozzle B, which communicates with the exhaust of the motor cylinders. The

Fig. 1.





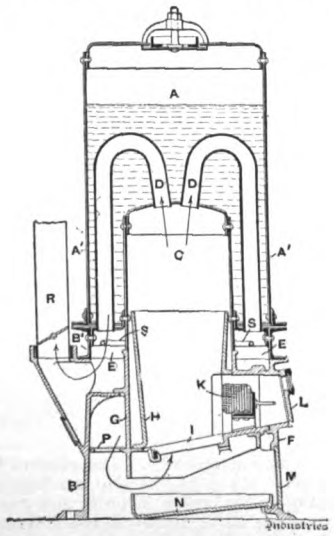


Fig. 2.

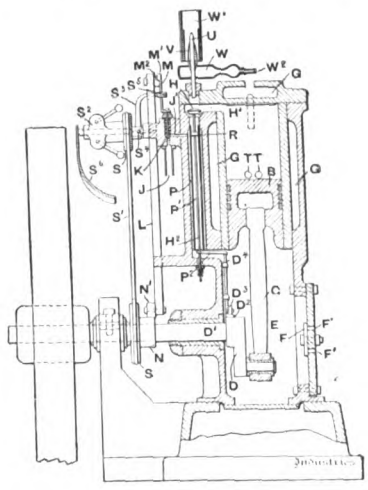
air passage C and second steam passage F surround the nozzle B. The openings F for the intake of air are placed at or about the level of the lower row of boiler tubes. The casing D is retained in its place by the flange G and ring J, which allow D to rotate partially over the lower part of the apparatus. The cap L revolves with the upper casing in order to exclude the ashes from its working face. The ports H correspond with passages I, and lead from the central nozzle B to the outer steam passage E. When these two sets of ports register with each other, the steam is free to escape by the annular orifice; but upon the external casing being partially rotated, the supply of steam to E is more or less intercepted, with the effect of increasing the draught. Six claims are made for this method of regulating the draught by means of the rotatable casing.—No. 6784. May 9th, 1887. 8*d.*



Steam Boilers.—*A. J. Boult, London.* (*A. Stehlik, Vienna.*)—The accompanying figure shows a vertical section of the boiler with its furnace and foundation. The boiler consists of two parts—the inner and lower part B¹, with the fire box C and flues D, and the outer shell A¹, which can be easily detached from the inner part. The boiler is mounted on a circular foundation B, which consists of the outer wall F, furnace G, fire grate I, and refractory wall H. The movable block K serves to regulate

the combustibles on the fire grate. The ash pit N can be reached through the door M, and is filled with water for the purpose of preventing the melting of the fire bars. The bottom of the boiler forms with the outer wall F and the furnace G a circular smoke box, into which the return flues D open. A circular air chamber P is formed round the furnace, and the air enters through an opening in it. The air is highly heated in this chamber before it passes into the grate. The return flues may be cleaned by means of a jet of steam from the tube S. The arrows indicate the course of the draught. The inventor claims the construction in two parts, and the combination of the return flues D with the smoke box E, air heating chamber P, and movable block K.—No. 1824. February 7th, 1888. 6*d.*

Twist Lace Fabrics.—*James Smith & John Smith, Nottingham.*—This invention relates to the production of alternately coloured diagonal squares on plain or spotted traverse twist lace. In any ordinary twist lace machine the inventors employ a warp of the required colour, and divide the width of the machine into groups of carriages and bobbins. Each group is sub-divided into two or more divisions, according to the number of colours of the thread on the bobbins. The carriages and bobbins are placed in whole groups or sub-divided groups of colours alternately, so that there may be an equal number of groups of each colour. The alternate diagonal squares are produced by traversing the front tier of carriages and bobbins from right to left or *vice versâ*, while the back tier is traversed in the reverse way. One claim is made.—No. 801. January 18th, 1888. 4*d.*

Gas Engines.—*C. Ridealgh, Sunderland.*—A sectional elevation of the vertical inverted type of gas engine is shown in the accompanying figure, with the present improvements embodied in its construction. D² is a cam on the crank D which actuates spindle H² of the valves R and H by means of the small roller D³ and bent rod D⁴. The crank and connecting rod work in the closed chamber E, and the air inside E is affected by the motion of the piston. The automatic suction valve F can admit air into the chamber through the holes F¹, and the valve H admits the combustible charge into the end H¹ of the cylinder. J is the gas supply pipe, and K is the gas admission valve, which is actuated by the rods L and M. A passage J¹ leads from the gas valve into the space P surrounding the pipe P¹; and opposite the end of J¹ are a series of holes in the pipe P¹, which when uncovered by the valve R give communication between the space P and the space between R and H. Through the valve R are a series of holes which control the passage of gas. There is a constant air communication between E and the under side of the valve H. The pulleys S drive the governor S², whose action is to throw the jaw M¹ out of gear with the catch piece M² on the end of the rod L, and thus to leave the gas valve K unmoved on its seat. The exhaust ports are shown at T; and U is a hollow tube closed at its upper extremity, and heated by the master light V. Starting from the position in the figure the piston commences to make its upstroke; the air inlet F and the gas inlet K are opened simultaneously, and the charges of air and gas are brought in until the piston reaches the upper end of the cylinder. The charge compressed in the former stroke is

now ignited, and the piston is driven downwards, compressing the air in E as well as the gas in P, until the exhaust ports are uncovered. At this point the cam D² raises the rod D⁴, which lifts up the valves R and H. The air in E rushes into the mixing valve R, and the mixed gases are thrust under pressure into the cylinder. The incoming charge is heated by the walls of the cylinder, and rapidly expands and helps to expel the products of combustion through T. The valves H and R are now closed, and the upstroke of the cylinder is made. The combustible charge is compressed, and a portion of it is forced up the ignition tube U. The gaseous mixture is fired at the conclusion of the stroke, and the operations are repeated as before. Four claims are made for the enclosed chamber, for the valves for mixing the gases, and for the arrangements for charging the cylinder.—No. 4511. March 26th, 1887. 8*d.*

Driving Carding Engine Cylinders.—*G. Ashworth & E. Ashworth, Manchester.*—In Patent No. 2432 of 1883, the present inventors provided for the vertical adjustment of the bearings of the cylinder shaft so as to make up for wear. In practice it is found that the reduction of the bearings by wear does not take place in a vertical direction on account of the pull of the belt gearing. In order to render the wear vertical the inventors have designed a new method of driving the shafts. The driving belt is passed over carrier pulleys so that the belt is deflected, and passes over the driving pulley in a vertical direction. The same means is employed to remove the disturbing effect of the driving of the "licker in," or the motion of the "licker in" may be transmitted from the other end of the driving cylinder. In the latter arrangement the ordinary pulley for driving the doffer is used as an intermediate pulley for deflecting the travel of the belt. Five claims are made.—No. 6586. May 5th, 1887. 8*d.*

Scutching Machine.—*W. S. Johnson, Newtownards, Down.*—The arrangements of the parts of this machine are designed for breaking and cleaning the fibrous material at the same time. Two pairs of cylinders revolve together, and are armed with flat angular blades. In between each angular blade is fixed a corrugated blade. One set of blades are placed radially on the ends of projecting arms, with their edges on the advancing side when rotating, and the other set with wavy edges are placed tangentially on the ends of angle iron arms. An inclined slide or rest is placed above the beaters and midway between their centres; the slide is curved for half the length, the remainder being level. The flax is held by clamps in the top of the inclined slide, with the ends hanging downwards. The flat blades break the hard wood, and the corrugated blades carry it away. When the flax is hung in position the clamps are pushed forward down the incline, and the drag on the fibre carries them on. Half the length of the fibre is cleaned in the first part of its passage through the machine; and after the clamp has been removed to the other end of the fibre the other half of the flax is cleaned on the return journey. Four claims are made.—No. 7050. May 14th, 1887. 8*d.*

Colour Printing Machines.—*J. Pollard, Hyde, and C. Mather, Manchester.*—This invention relates to the construction of machines employed in printing textile fabrics, &c., and the chief object is to add a supplementary vibrating motion to the thin steel blade which is used for removing the surplus colour from the printing rollers. The revolving part, in which the eccentric cam groove is formed, is mounted loosely on the bowl shaft, in such a manner that it can be moved longitudinally along the

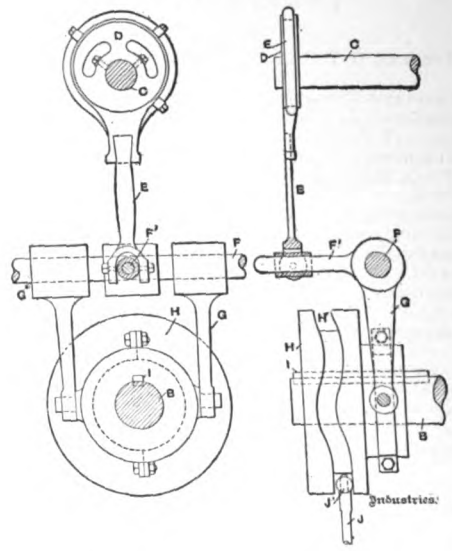


Fig. 1. Fig. 2.

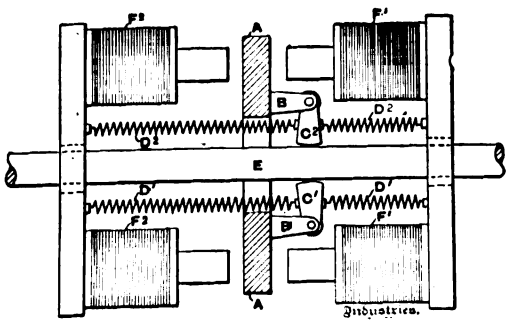
shaft. This revolving part has also a reciprocating motion imparted to it, so that the "doctor," or thin steel blade, receives a compound vibrating motion. Fig. 1 represents an end view, and Fig. 2 a side view of the new connections. B is the bowl shaft, C the revolving back shaft, and D an eccentric connected by the rod E to an arm F¹ on the rocking shaft F. Two tappet levers G are fixed to the shaft F, and engage a groove in the boss of a grooved cam H. The latter is mounted, and free to slide on a feather key I; and a bowl J¹ on the end of the rod J lies in the cam groove H¹. The rod J is connected to one of the doctors. When the bowl shaft is driven the sliding cam H will impart a reciprocating motion to the doctor by means of the cam groove H¹ and the bowl J¹. The doctors also receive a second vibrating motion by the eccentric D revolving with the back shaft C, and through the parts E F¹ F H I. One claim is made.—No. 6192. April 28th, 1887. 8*d.*



ELECTRICITY.

Incandescent Lamps.—*C. M. Dorman & R. A. Smith, Manchester.*—The object of this invention is to simplify the fittings of the porcelain shades of pendant incandescent lamps. The reflecting shade is formed of one solid piece of porcelain or glass ware, and has a central hole for the passage of the conducting wires. The lamp holder has projections on its metallic base, and is attached to the shade by means of screws passing through holes in the shade and the projections. Three claims are made.—No. 506. January 12th, 1887. 6d.

Electric Arc Lamps.—*A. Siemens, London.*—The two carbon holders are mounted on two vertical rods, one of which has a screw on its lower part and screws through the lower carbon holder, while the other has a screw on its upper part and screws through the upper carbon holder. The holders also have eyes through which the non-threaded parts of the rod pass, so that the rod that actuates one carbon holder acts as a guide to the other. The screw threads of the rods are both the same hand, but the threads of the rod for the upper holder are made double the pitch of the lower. The rods carry toothed wheels which gear into each other, so that contrary rotations are imparted to the rods. To obtain an automatic advance of the carbons, the wheel of the rod for the upper holder has a rim within which is a spring brake strap. The two ends of the strap are connected to one end of a lever in such a way that when the lever is moved in one direction it first causes the strap to bite on the wheel rim, and then carries the wheel with it by means of the brake and rotates the rods. When the lever is moved in the contrary direction it releases the brake strap, and the lever can move back to the original position, leaving the rods stationary. The lever is pivoted to a bar, one end of which is connected to an adjustable spring, while the other end is connected to the armature of an electromagnet, whose coils are in a shunt of the lamp circuit; and the coil connection between the coils and the shunt circuit is made by a contact spring on the armature when this is removed from the magnet. The spring connected to the bar that carries the brake lever is so adjusted that when the carbons of the lamp are at a normal distance apart the current passing through the shunt is too weak to cause the magnet to attract the armature in opposition to the spring, and consequently the bar and lever are held back when no feed is required. When the resistance of the arc has increased the shunt circuit is strong enough to attract the armature, and the rods are rotated. When this feed takes place the attraction of the armature causes the connection between the shunt and electromagnet to be broken, and the armature is not attracted any more. Thus a step by step automatic feed is imparted to the carbons. Three claims are made.—No. 6987. May 12th, 1887. 8*d.*

Digitized by Google

REGULATION OF ELECTRIC CURRENTS.—*F. Ross & A. Franzen, Vienna.*—The grippers C¹ C² are pivoted to the projections B on the plate A, and the springs D¹ D² hold the grippers in the position shown in the figure. Between the grippers is a rod which forms part of the regulating devices, and which is arranged so as to be entirely free from the grippers when in their normal position. When the plate A moves in a direction parallel to the axis of the rod E the springs D¹ D² will tend to

hold the grippers in their original position, while the fulcrums B move along the plate A, causing the grippers to assume an inclined position, and to bear against the rod E and carry it along with them. When the plate returns to its former position the rod E will be released, but if the plate continues its movement in the opposite direction the rod will be moved along with it. The reciprocating movement of the plate is obtained by two electromagnets F¹ F². The rod E may be connected with a series of rubbing contacts, and its motion will thus throw a number of resistances in and out of circuit; or the rod may be coupled directly to the regulating devices of the motor engine. The inventors claim the method of producing a rectilinear reciprocating movement by the rod grippers and plate, as described.—No. 13148. September 28th, 1887. 6*d.*

CHEMISTRY.

COLOURING MATTERS.—*A. Kern, Basle.*—This invention relates to the preparation of the methylic ether of gallic acid, and of colouring matters which may be derived from it by the action of nitroso derivatives of secondary and tertiary aromatic monamines. In order to prepare the ether, twenty parts of crystallised gallic acid are dissolved while hot in fifty parts of methyl alcohol; dry hydrochloric acid gas is introduced into the solution until absorption ceases. On cooling, the new ether crystallises out. Another method of preparing this ether is to mix forty parts of tannin and eighty of methyl alcohol with twelve of concentrated sulphuric acid. In order to manufacture the purple colouring matter, ten parts of the methylic ether of gallic acid and twelve parts of hydrochloric nitroso-dimethylaniline are mixed with eighty of methyl alcohol; the mixture is boiled for four hours, and well agitated. The colouring matter forms gradually in small brown needles. Two claims are made for the process of manufacturing methylic ether of gallic acid, and for the colouring matter respectively.—No. 5953. April 23rd, 1887. 6*d.*

EXTRACTION OF COPPER FROM ORES.—*J. Perino, Charlottenburg, Germany.*—The novelty of this invention consists of the process of sulphating the sulphide of copper and iron by means of nitric iron salts. These iron salts readily give up their oxygen at a moderate heat, and decompose into gaseous oxides of nitrogen and ferric oxide. The disposable oxygen combines in the nascent state with the sulphides of copper and iron, and forms the corresponding sulphates. The resulting materials are lixiviated with warm water, and the copper in the vitriol lye is precipitated by a usual method. In carrying out this new method practically, a regenerative process is employed for the object of producing the nitric iron salt. The lye of green vitriol is mixed with a concentrated solution of nitrate of lime, with the result that gypsum and ferrous nitrate are formed. The latter salt is run off into the receivers of the sulphating apparatus. The nitric oxides produced in the sulphating process are conducted by a slowly passing air current into the receivers, and a further oxidation of ferrous salts takes place in consequence. The nitric oxide thus obtained is oxidised again by the oxygen in the air, and nitrous vapours are produced; these are absorbed by the carbonate of lime in the water. A gradual formation of nitrate of lime now takes place. The further conversion of ferrous into ferric nitrate is effected in the usual way. The inventor claims the process of disintegration of copper pyrites, after they have been partially roasted, by heating them in the presence of nitric iron salts.—No. 2019 February 10th, 1888. 4*d.*

COLOURING MATTER.—*R. Chadwick & J. W. C. Chadwick, Kidderminster.*—This colouring matter is produced for the object of applying it to dyeing, staining, and printing. In twelve quarts of water are dissolved 12oz. of atlas violet, 4oz. of 3 R aniline scarlet, 2lb. of nigrosine, 1lb. of Irish moss, 6lb. of indigo extract, and 1lb. of oil of vitriol. These ingredients, when incorporated, will produce about 34lb. of dye, and are ready for use after being strained through cloth. This colouring matter will dye blue, black, and other colours, according to the amount of the pigment and sulphuric acid used. The advantage of the process is that the dyeing is complete in one operation instead of two. One claim is made for this colouring mixture. —No. 3280. March 3rd, 1887. 6*d.*

ABSORPTION TOWERS.—*H. P. Weidig & R. C. Remmey, Philadelphia.*—The absorption towers used in the manufacture of hydrochloric and nitric acid are made of such a form in this invention that they may be used continually without being taken apart for re-filling. The tower is composed of cylindrical sections of earthenware, which are open at the top, and closed at the bottom. A channel runs round the top of each section, in order to form a support for the section immediately above. There is an opening in the bottom of each section, and a vertical partition disconnecting the opening from the rest of the interior of the section extends three-quarters of the height of the section; the sections are so disposed that these openings shall be alternately at opposite sides of the tower. An outside open pipe communicates with the bottom of each section, and extends to the same height as the corresponding internal pipe. When the interior of each section has been filled with water, the fumes of the acid are led into an opening in the roof of the tower. The vapours find their way through the alternate openings in the bottoms of the sections, and in their travel down the tower become absorbed by the water. During this process a hygrometer is placed in each exterior pipe, in order to test the degree of saturation of the solution, and after the water has absorbed all the acid that it can hold, it is drawn off through the exterior pipes by means of syphons. Two claims are made. —No. 1082. January 24th, 1888. 6*d.*

AMALGAMATOR.—*W. P. Thompson, Liverpool.* (*J. A. Sperry, New York.*)—This apparatus for extracting gold and silver from the ore by means of mercury, has no mechanical moving parts to effect the contact of the metals or the passage of the ore. A tray is mounted in a suitable frame, and a series of short pipes are inserted in its bottom; they extend a short distance below the tray and rise to a certain height above the bottom of the tray. The tray is partially filled with mercury to about the level of the mouths of the tubes. The water and ore is delivered through a hopper into the mercury, and the amalgam and water runs over through the tubes into a similar tray below. It is preferable to use a series of trays one under the other, with their discharge tubes arranged so as not to register with one another. In each tray the mercury rests upon a copper plate, and a carbon plate is sustained on rubber standards at a distance above the mercury. The upper plate allows the free passage of the water and pulp by being perforated with holes, which register with the tubes in the tray above. The carbon plates are connected to the cathode, and the copper plates to the anode, of an electric generator. Three claims are made.—No. 7370. May 20th, 1887. 8*d.*

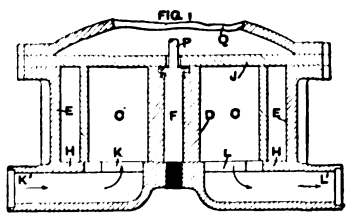
ALUMINIUM ALLOYS.—*W. A. Baldwin, Chicago, U.S.A.*—In carrying out this process, the inventor mixes four parts of dry pulverised clay, one part of charcoal, and twelve parts of common salt, and brings the mixture to a state of fusion in a crucible. Into the fused mixture is poured some molten metal, such as iron, steel, copper, or zinc, with which it is required to make the alloy. After standing half an hour the molten alloy is run off and cast into pigs. Two claims are made.—No. 2584. February 21st, 1888. 4*d.*

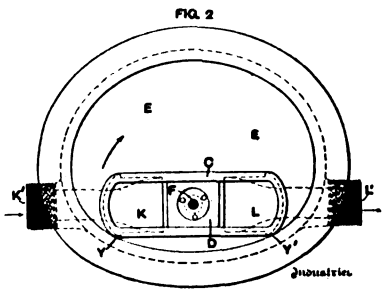
COLOURING MATTER.—*C. D. Abel, London.* (*Meister, Lucius, und Brüning, Höchst am Main, Germany.*)—In producing the dialkyl-amido-benzophenones, the inventors make use of the halogen compounds of the anilides or naphthalides of benzoic acid. The anilides and naphthalides of benzoic acid are converted into the halogen compounds by means of chloro-phosphorus, these compounds are condensed by means of dimethyl-aniline or any other tertiary aromatic base, and the products of the condensat on are treated with diluted acids. To claims are made.—No. 5257. April 9th, 1887. 6*d.*

MISCELLANEOUS.

WATER METERS.—*S. A. de Normanville, London.*—This invention relates to that class of water meters in which a slotted piston has a combined rotary and sliding motion upon a pivot. Fig. 1 is a cross section and Fig. 2 is a plan of one form of the improved apparatus. The piston C is formed with an internal slot, in which the boss D slides; the boss is pivoted eccentrically within the chamber E upon the stud F. The shape of the chamber is such that the piston shall always remain in contact with the walls of the chamber at both its ends. An inlet port K and an outlet port L are provided at the bottom of the chamber E, and are in such a position that, when the piston is at right angles to the minor axis as in Fig. 2, they are covered by the piston. The water enters through the inlet port K, and

FIG. 1





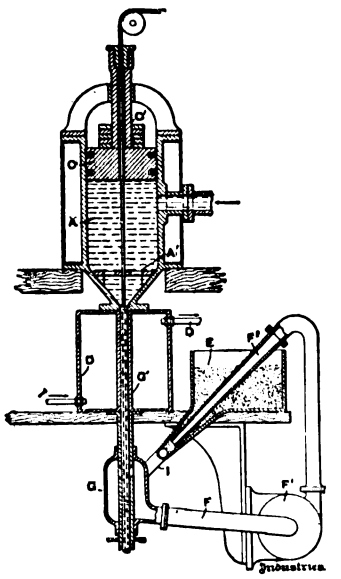


FIG. 2

communicates a sliding and rotary motion to the piston; it then enters between one side of the piston and the chamber wall, and assists in the rotary movement, while the water on the other side of the piston flows away through L. When the piston is in a position at right angles to that shown in Fig. 2, the ports are cut off from communication with the interior of the piston. The further oscillation of the piston is similar, but in reversed order to the first part of its motion. The inventor claims the combination of the slotted piston, having a combined rotary and sliding motion, with the chamber, whose walls are such that the ends of the piston always touch them, and that the flow of water from inlet to exhaust is prevented without the necessity of any fixed abutment.—No. 220. January 6th, 1887. 8*d.*

FLUES OF REGENERATIVE CHAMBERS.—*W. Tomlinson, West Hartlepool.*—The inventor has found that it entails a great defect to build the flues with straight sides from end to end, on account of the particles of dirt and scoria suspended in the current of air being intercepted by the sharp corners, and so forming an accretion on the brick work. The inventor proposes to overcome this defect by providing bell-mouthed flues, so that the force of the current will be enabled to carry the suspended matters to another part of the stove, from whence it can be more readily removed. Each side of the flue is caused to diverge at a suitable distance from the end. The inventor claims the employment of diverging or bell-mouthed ends for the flues for the purpose described.—No. 1959. February 9th, 1888. 6*d.*

INSULATING ELECTRICAL CONDUCTORS.—*D. Nicoll, London.*—The material used for insulating the wires is a mixture of gas pitch and cotton foots pitch in certain proportions. After this mixture has been heated it is introduced into a cylinder, where it is subjected to pressure by the piston, so as to force it through a tube of small diameter. At the same time the wire is passed in a tightly stretched condition through the same cylinder and tube. The accompanying figure illustrates the apparatus specially designed for this purpose. The wire is passed through the tubular rod C¹ of the weighted piston C, and through a guide in the jacketed cylinder A, so as to insure its entry into the tube

G¹, in a central position. The tube is enclosed by the refrigerating tank D, through which a current of cold water is caused to flow. In some cases the wire is given an outer coating of mica as it passes through the tube; for this purpose two or more conduits I are made to enter the chamber G. The hopper E contains the powdered mica, which is discharged in regulated quantities by means of a circulating current of air produced by the fan F¹, and passing through the pipes F, F², I, and chamber G. The tube G¹ has slits in it through which the mica can reach the surface of the coated wire. Three claims are made for this apparatus and for other details.—No. 6933. May 11th, 1887. 8*d.*

POLISHING TEXTILE FABRICS.—*W. Baxter, Bradford.*—This invention consists of an arrangement of revolving brushes, under which the piece of woven fabric is caused to travel. The shafts of several of these brushes are mounted on a frame, and underneath each brush are placed two rollers of wood or metal, whose spindles revolve in square movable bushes. It is necessary to raise these rollers in order to bring the surface of the fabric into contact with the revolving brushes. For this purpose the inventor employs two shafts, with heart-shaped cams fixed on them; the cams work against the square brass bushes, and the shafts are driven by bevel wheels, which receive their motion from a hand wheel. By these means the rollers can be raised to the required position after the piece has been placed in the machine. One claim is made.—No. 3662. March 10th, 1887. 8*d.*

INDICATORS FOR STEAM ENGINES.—*J. Buchanan, Glasgow.*—This invention comprises an improved ratchet spring detent device for preventing the rotation of the spring cylinder of the indicator while the card is being taken off and replaced by another. The usual spur ratchet wheel is mounted at the lower edge of the rotating spring barrel, in order to actuate it against the power of the internal spring. A ratchet pawl is mounted vertically on a joint at the lower front edge of the bracket supporting the barrel; the upper end, on which the gripping pawl is formed, is tilted in and out of gear with the teeth of the ratchet wheel by the action of a light curved spring lever, working in a groove in the back of the pawl. One end of the spring lever oscillates on a joint pin, secured by a washer and circular bearing on the front edge of the bracket, and a handle is fixed at the free end of the lever. The narrow slot is preferably cam-shaped in a vertical direction, and when the free end of the spring lever is pressed up in the groove beyond the fulcrum of the pawl, it retains the pawl in gear with the ratchet teeth, and yet allows the barrel to turn when actuated by the motive cord, and holds it there, preventing its return by the internal spring. When the spring lever is pressed down in the groove to the lower end below the fulcrum, it immediately takes the pawl out of gear, and allows the barrel to be turned in the backward direction by the internal spring, and leaves it free to oscillate. Two claims are made for the ratchet, pawl, and spring lever, for both moving it and retaining it in its engaged and disengaged positions.—No. 6773. May 9th, 1887. 8*d.*

Digitized by Google

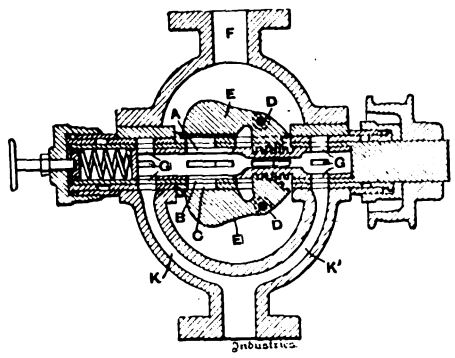
RAILWAY AND TRAMWAY SLEEPER.—*G. F. Redfern, London. (F. Coblyn, Seraing, Belgium.)*—The improved sleeper is made of rolled steel somewhat in the shape of a T in cross section; the horizontal top part of the sleeper is curved downwards at the outer edges, and is formed with a central gutter. This form is given to the sleeper in order to facilitate rolling, and at the same time to diminish the weight while giving additional sectional strength. The inventor makes two claims for this shape of sleeper.—No. 6030. April 25th, 1887. 4*d.*

REFRIGERATING APPARATUS.—*J. Dauber, Barmen, Germany.*—The ice machines hitherto in use require so great a supply of water that the cost of production of ice is increased when water is scarce. The methods pursued by the inventor, and described in this specification, are intended to reduce the cost under these circumstances. In one method the force pipe of the ammonia gases is placed in the bottom of the refrigerator without going through a condenser. In another method the use of the condenser is retained, and the cooling of the ammonia pipes and the condensation of the gases are effected by the salt liquid from the refrigerator being forced into and through the condenser, and back to the refrigerator, in a continuous circulating stream. The suction pipe leading from the refrigerator to the compressor is of serpentine form, in order to cool the water to the greatest possible extent. The other pipes leading from the refrigerator to the condenser and back again are also of serpentine form, for the same reason. Four claims are made.—No. 5600. April 18th, 1887. 11*d.*

WINDING YARN ON SPINDLES.—*I. C. Schofield, Elland, Yorkshire.*—The inventor dispenses with the clicks and springs usually employed on mules and twiners, and introduces a clutch motion instead. A disc is fixed to the tin roller shaft, and gears internally with a drum or pulley whose inner surface may be either smooth or indented. The pulley is loose upon the shaft, and has a flange which overlaps the disc. Another pulley with a side flange overlapping the disc prevents the clutch from operating until required; this pulley is made so that it may be slid along the shaft upon prongs on the boss of the disc, and revolve along with the shaft and the disc. The connection of the clutch motion may be made by the locking of the fallers, or by the revolution of the cam shaft. The inventor claims an internal wedge clutch overlapped by a pulley with a side flange, to prevent the gearing or "scotching" of the clutch during the "backing off" process.—No. 4156. March 19th, 1887. 8*d.*

PNEUMATIC SEPARATOR FOR GRANULATED MATERIALS.—*H. Dietz, Berlin.*—This apparatus is employed to procure the separation and sub-division of the particles of a granulated mass, according to their size and specific weight. Two frames are supported in a containing case; the upper frame is capable of vibration by means of a crank and links, and the lower frame is fixed, and has a number of holes in the bottom which are covered by a wire gauze. The two frames are joined by an elastic material; a number of bellows are fixed in the upper surface of the vibrating frame, and their flaps are worked automatically by a rod and crank. Valves are also placed in the side of the upper frame, which will allow only the entrance of air. The draught thus caused carries the lighter portions of the granulated mass through a shoot in the end of the apparatus, while the heavier portions fall through the sieves. Three claims are made.—No. 2123. February 11th, 1888. 8*d.*

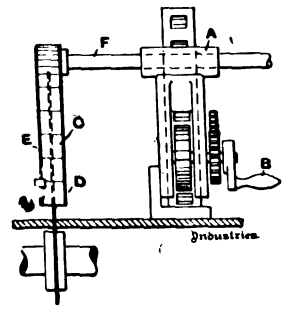
ROLLED GLASS.—*J. Armstrong, London.*—The object of this invention is to insert wire work into the interior of sheets of glass while being rolled. The apparatus employed for this purpose consists of a roller of metal either flanged, grooved, or plain, which is made to travel in front of the ordinary large roller, behind the wire work, and at a distance above the surface of the table. The wire work is first fixed to one end of the table, and is then brought underneath the large roller, under the second roller, and carried above to a receptacle that contains a roll of wire. The receptacle travels along with the two rollers, and delivers the wire work before the first roller and against the incandescent glass. The action of the first roller is to press the wire work against the glass; the motion of the second roller and the tension of the wire causes a portion of the molten glass to be forced through the meshes of the wire work. This part of the glass is received by the heavy roller and is squeezed against the table, and the upper surface of the glass is thus made smooth. The first roller is mounted upon travelling gear, which is made to gradually approach the surface of the rolling table. This process is applicable to the rolling of very thin sheets of glass with wire in the interior. Two claims are made.—No. 5701. April 19th, 1887. 6*d.*



WOOL SCOURING MACHINE.—*C. H. Smith, South Geelong, Victoria.*—In the improved machine the wool is carried along through the liquor in the washing cistern by rakes or prongs, which are attached to two endless chain belts supported on hexagonal sheaves. The sheaves, which are situated at the same end as the squeezing rollers, have the necessary motion imparted to them. The prongs engage with the wool at one end of the cistern, and carry it down under the comb and immersion bars, and into the liquor. When the wool arrives at the end of the cistern, the prongs rise perpendicularly and deliver the wool through the squeezing rollers. When clear of the rollers, the prongs are canted over, and are carried horizontally along the top side of the chain belts until they arrive near the other end. They are then righted, and brought to a position at right angles to their supporting links, and are again in readiness to engage with the wool. The inventor makes four claims for the endless chains carrying the prongs, and for tail pieces on the prongs which engage against striking bars at the back of the sheaves for the purpose of raising and canting the prongs.—No. 1450. January 31st, 1888. 8*d.*

SUCTION BOXES FOR PAPER MAKING MACHINES.—*G. Bird, Leith, Midlothian.*—The object of this invention is to diminish the wear to which the endless wire gauze cloth is subjected whilst passing over the suction boxes. The wire is supported on two rollers whilst passing over each suction box; and these rollers are driven by gearing so as to have the same surface velocity as the wire. There is thus no friction between the rollers and the wire. The suction is arranged to take effect on the under side of the wire between the two rollers, and a space is there formed, having the wire for the top and parts of the rollers for its front and back sides, and adjustable pieces for its ends; its bottom is made of a horizontal piece of wood or metal, with its front and back concave edge surfaces bearing on the rollers. The bottom piece is made with a central opening communicating with the space beneath, which is connected at one of its ends with a pipe leading to the suction pumps. Troughs are formed round the under sides of the rollers, and are more or less filled with water when the apparatus is in action; beneath the bottom piece there is fixed a sheet of rubber cloth with loose ends extending some distance down and under the rollers, in such a way that if there is any leakage between the rollers and the bottom piece the loose ends of the rubber cloth will be drawn up to stop the leak. The end pieces fit tightly down on the bottom piece and on the rollers, and are provided with rubber strips to bear up against the wire; they are also adjustable by screw spindles so that they can be placed immediately under the deckles to suit the width of the paper. Three claims are made.—No. 6945. May 12th, 1887. 8*d.*

REFRIGERATING MACHINES.—*W. P. Thompson, Liverpool. (J. B. Craft, New York.)*—This invention relates to a device for preventing the boiling over of the liquid contents of the distilling retorts in absorption ice machines. The hot distilled gas is used on its passage from the retorts for the purpose of heating the incoming cold aqua ammonia that supplies the retorts. The aqua ammonia is heated in the distilling retorts by steam coils. The gas passes up into a gas receiver, and is thrown down to the bottom of it by means of diaphragms before it can pass up to the rectifier. All the liquid which has been carried bodily from the still is deposited at the bottom of the receiver, and a pipe carries it directly back to the still. The hot gas passing into the rectifier is brought into thermal contact with the descending supply of cold aqua ammonia without coming into actual physical contact with it. The gas gives up its heat to the liquid, and thus loses its watery vapour; the strong aqua ammonia takes up the heat, and is thus prepared for being heated in the retort. Sixteen claims are made.—No. 1419. January 31st, 1888. 8*d.*

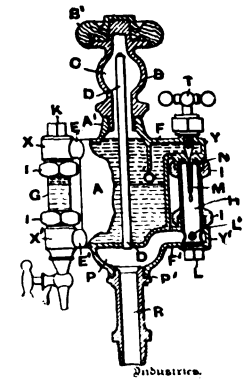


GERMAN PATENT ABSTRACTS.

GOVERNORS.—*G. Goepel, Merseburg.*—This apparatus consists of three hollow spindles A B C, which are revolved by means of a belt and pulley keyed to spindle B. The steam or compressed air enters through F into the chamber surrounding the governor, and from there through perforations G G in the spindles A B C

into the passages K K', and into the motor. If the speed of the motor exceeds a certain limit, the weights E E swing outwards round the pivots D, thereby forcing spindle A to the left, and diminishing the area of the perforations.—No. 42713. July 3rd, 1887.

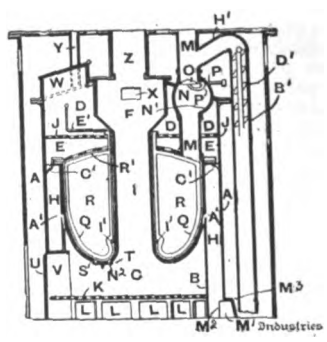
CIRCULAR SAWS.—*J. B. Schmidt, Munich.*—This invention relates to an improvement in guards for circular saws. The guard consists of two semi-circular pieces D E and a flat bar C



arranged so as to slide along the circumference of D and E. The guard is attached to a shaft F, which is adjustable in the boss A in a horizontal direction, while a vertical adjustment is effected by moving the boss A, and with it F and the guard, along the rack by means of the handle B and spur gearing.—No. 42712. June 30th, 1887.

UNITED STATES PATENT ABSTRACTS.

TANNING.—*A. Warter & H. C. Koegel, Newark, New Jersey.*—In the new process of tanning here described the skins are first depilated in any ordinary manner, and then subjected to the action of a neutral solution, which is formed by dissolving hydrated aluminium sesquioxide in an acid. A second solution is afterwards applied to the skin, consisting of a neutral solution of hydrated chromium sesquioxide in an acid. One claim is made.—No. 380708, dated 10th April, 1888.



PRESERVING SUBMERGED TIMBER.—*H. L. Ricks, Eureka, California.*—This method of preserving timbers which are immersed in salt water consists in keeping the timbers continually soaked in fresh water. This is done by boring a central hole throughout the length of the piece of timber which is exposed to the action of the sea water. The upper ends of the holes in the timbers are connected by a pipe with one another and with a cistern of fresh water. The fresh water thus has a continual access to the interior of the timber, and the salt water is prevented from penetrating it. Three claims are made.—No. 380820, dated 10th April, 1888.

LUBRICATOR.—*J. Powell, Cincinnati.*—The tube R is screwed to the cylinder of the engine, and the steam enters through it into the distributing chamber P. The oil is contained inside the vessel A, which is provided with a gauge glass G and a sight feed H. The steam enters the tube D and becomes condensed inside the vessel A. The oil is thus raised in level in A, and in consequence gradually drops out of the nozzle M into the

chamber P. The screw T regulates the rate of dropping of the oil, and the top piece B C can be removed for the purpose of introducing the oil. A flange O is suspended opposite the entrance to the channel F, and the tap J allows the vessel A to be emptied. Four claims are made.—No. 379243, dated 6th March, 1888.

SEWAGE FURNACE.—*J. Vladyka & W. M. Mitchell, Newton, Iowa.*—The filth and sewage is placed in the retort R through the opening M. There are two furnace grates at J and K respectively. The retort is supported on the inner shell B, and between the inner shell and the outer shell A is a flue along which the

down draught travels from the upper to the lower furnace. The products of combustion pass up the central flue F. A counterbalanced valve is placed in the pipe M so as to allow the refuse to be poured into the retort, and at other times to keep shut. The perforated cover is placed over the retort, and any fumes emitted from the combustion will pass into the second furnace on the grate J. In the interior of the retort is placed a scraper Q, and a valve S in the bottom allows the ultimate remnants to be evacuated. Ten claims are made for this furnace.—No. 379189, dated 6th March, 1888.

INK.—*M. C. Lefferts, New York, and J. H. Stevens, Newark, New Jersey.*—This invention relates to the composition of an ink for printing upon celluloid or other pyroxyline compounds. An insoluble pigment in powdered form is mixed with a gum which holds the particles together, and a solvent for pyroxyline is added to this mixture. The gum which is preferably used is shellac, and the solvent consists essentially of oil of cassia. Five claims are made.—No. 380654, dated 3rd April, 1888.

LOOM FOR CROSS WEAVING.—*C. A. Littlefield, Fall River, Massachusetts.*—In addition to the ordinary harness, and a series of half heddles, the loom is provided with a stationary supplemental reed which has a series of needles pivoted to its top rail. The reed and needles can be deflected to the left or right by laterally inclined lugs on a pattern cylinder; and the warps which are raised by the ordinary harness are thus deflected to one side or other of the tie warps passing through the needles. The warp threads passed through the loops of the needles may be raised as desired by the half heddles. Four claims are made. —No. 380760, dated 10th April, 1888.

The full specifications of the British and United States patents, and the Official Journals of the German Patent Office, from which the above abstracts have been compiled, and the Official Journal of the United States Patent Office, may be seen by subscribers and clients at the Reading Room, Manchester Office of INDUSTRIES, *where also Patent Indexes from* A.D. 1617 *may be consulted. Copies of the British specifications may be obtained on application to* H. READER LACK, Esq., *Comptroller-General, Patent Office, Southampton Buildings, London, W.C. The published price must be remitted, together with a sum sufficient to cover postage, which may be reckoned at ½d. for every 10d. or fraction of 10d. Remittances exceeding one shilling must be made by Post Office Order.*

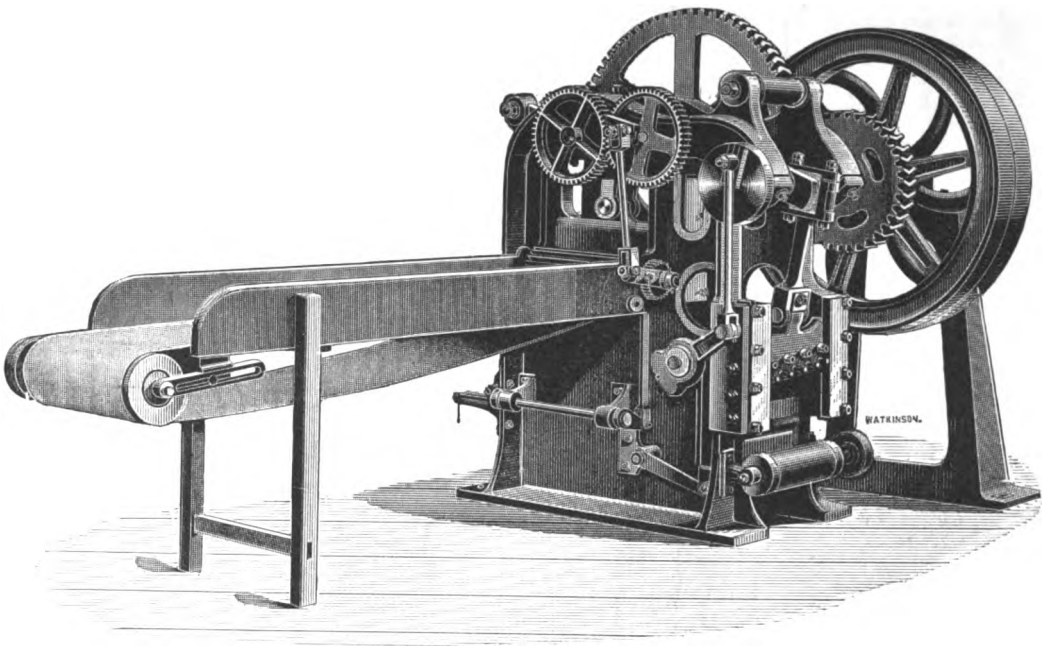
IMPROVED RAG CUTTING MACHINE.

The accompanying illustration represents a duplex guillotine rag cutting machine patented by Mr. Nuttall, and constructed by Messrs. Bentley & Jackson, paper mill engineers, Bury, near Manchester. The machine consists of a strong frame and two heavy knives bolted to cast iron blocks and moving vertically up and down in slides. Both knives are actuated by cranks from a shaft carrying a heavy fly wheel, which is driven by means of a belt. The cutters are arranged at right angles to each other and at different levels. The material under operation is put on a travelling apron, from which it is drawn under the first cutter by means of feed rollers, and cut into pieces of suitable size. These pieces then slide down on a polished metal plate on to a second apron arranged at right angles to the first one, which supplies the feed roller which draws the cut material endways under the second cutter. By means of this the material is cut into nearly square pieces. Both travelling aprons have an intermittent motion, and by adjusting their speed, pieces from 1in. to 6in. square may be cut. When blunt, the knives may be taken off, ground, and re-set, the adjustment being effected by set screws. The makers claim that this machine will cut all kinds of rags, such as bagging, jute, sail cloth, rhea, Adansonia fibre, linen thread, thread waste, &c., at a rate of from 20 cwt. to 30 cwt. per hour.



THE MANCHESTER ROYAL JUBILEE EXHIBITION.

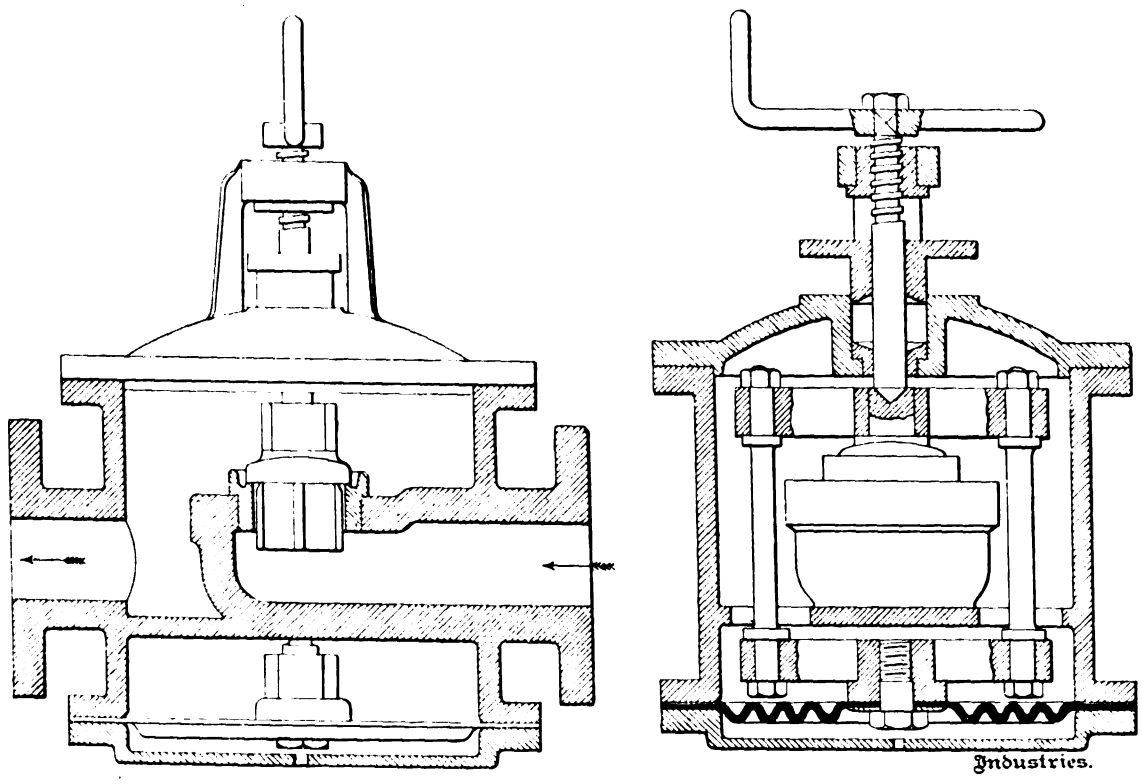
Irish Section *(concluded from Vol. III., page 489)*.—An exhibit of original scientific apparatus was contributed by Professor G. F. Fitzgerald, of Trinity College, Dublin. The first instrument was a sine and tangent galvanometer, which combines both instruments, and has four interesting peculiarities: (1) The windings of the coils are visible through the plate glass sides, so as to be capable of easy measurement *in situ*; (2) the position of the needle is read by reflections of a cylindrical scale in two rectangular mirrors whose intersection is horizontal, and which are attached to the magnet. These mirrors reflect images of opposite sides of the scale to a fixed mirror which reflects them into a microscope, in which by means of a micrometer it is possible to read accurately the position of the line which is the same in the two images; (3) this cylindrical scale is affixed to the base of the instrument, and the coils can be rotated round it, so that when the instrument is used as a sine galvanometer, its position is read by reflection in the rectangular mirrors attached to the magnet of a pointer attached to the coils; (4) by a slight modification of the suspension, a beam of light can be reflected from a mirror connected to the magnet at 45° to its axis of rotation, and can emerge through the plate glass side of the instrument and fall on a horizontal scale, where it will measure the tangent of the deviation instead of the tangent of twice the deviation, as in ordinary reflecting galvanometers. The meldometer shown is an instrument for facilitating the identification of small quantities of minerals by comparative observations on their melting points, and for observing the phenomena of their fusion and ebullition. It consists of a strip of platinum arranged to traverse the stage of a microscope, and heated by a current derived from two Grove's cells. On this strip the fragments of the mineral, or if for comparative observation, of two or more minerals, are placed. The temperature of the platinum is then raised by gradually diminishing a resistance placed in circuit with the battery and meldometer, the behaviour of the substance being meanwhile observed through the microscope. To effect the elevation of a temperature automatically, a resistance, consisting of a rod of carbon fitted in a vertical glass tube, is employed. Professor Fitzgerald showed two sets of apparatus for measuring the densities of gases. Both methods depend on the determination of the amount by which a body is buoyed up when immersed in the gas.

A very interesting exhibit was the model for illustrating the electromagnetic and luminiferous properties of the ether, of which a detailed description is almost necessary. The model consists of a series of wheels, rotating on axes fixed perpendicularly in a plane board, and connected together by india-rubber bands The axes are fixed at the intersections of two systems of perpendicular lines, and each wheel is connected with each of its four neighbours by an india-rubber band. Thus all the wheels can rotate without any consequent straining of the system if they all rotate at the same rate. If, however, some of the wheels are rotated through a different angle from others, the india-rubber bands will be strained. If it be desired to represent a region in which conducting matter exists, it will be represented by removing the bands from a set of wheels. Suppose the bands are removed from the regions A and B, and from the connecting line A B, then we can represent the charging of these regions with opposite electricities by introducing some mechanism by

IMPROVED RAG CUTTING MACHINE.

Constructed by Messrs. Bentley & Jackson, Bury, near Manchester.

means of which the wheels on opposite sides of the line A B can be rotated in opposite directions. The model is not intended to illustrate in any way the connection between the ether and matter; indeed, one of the advantages claimed for the model is, that the study of it so distinctly emphasises the distinction between the phenomena depending on the general properties of the ether by itself, and those depending on its connection with matter. For instance, from the very case we have just considered, we get impressed upon us that it is by means of matter only that we can get a hold on the ether so as to strain it. As the object is not to illustrate the connection between matter and ether, any rough method of turning the wheels so as to create the proper strain will do well enough, as it is not the method of producing but the nature of the strain produced that is to be considered. Having once rotated these wheels, we may replace the bands along the line A B, and we have the state of the ether between two oppositely electrified bodies represented on the model. It will be observed that half the india-rubber bands are strained, and that in lines running round the bodies the tight side of a band is always away from one body and next the other. This represents the polarisation of the ether. The late Professor Clerk-Maxwell defined polarisation as a state in which the opposite sides of each element are in opposite states. Now, the opposite sides of each band are in opposite states—one side loose, the other tight; and so it can very well represent the polarised state of the ether. The displacement producing the polarisation is due to the different rotation of the wheels carrying the band causing more of the band to be at one side of the wheels than at the other—less at the tight and more at the loose side of the pair of wheels, and this represents the electric displacement producing the polarisation. The direction of this displacement is at right angles to the line of the bands that are strained, and is out from one body and in towards the other all round. Considering the other properties of the ether that are represented by the model, we observe in the first place that during the time polarisation is taking place the wheels are rotating, and that the rate of rotation of the wheels is proportional to the rate of increase of polarisation, and that the direction of the axis of rotation is perpendicular to the direction of the displacement. Hence it is seen that the magnetic force is properly represented by the rate of rotation of the wheels, and its direction by the axis of rotation. The model, although simple in construction, is very useful, and its careful study will greatly assist the student in obtaining definite physical conceptions of many of the more abstruse phenomena depending on the ether.



Another exhibit was a photometer made of solid paraffin, or any other translucent substance, invented by Mr. J. Joly, of the University of Dublin. The arrangement is at once simple and effective. The instrument depends upon the fact that if a prism be cut from a translucent body, and so exposed to a source of light that one only of its faces is illuminated, the light diffused through the substance and reflected out through the illuminated faces of the prism gives it an appearance as if lighted up internally. The effect is, in fact, as if the prism itself was a source of light. Two such prisms laid together on smooth faces, and receiving light from separate sources, if placed so as to be at opposite sides of the plane of division, appear as if each was emitting light proportional in intensity to the source of its supply. The double prism has the appearance of two luminous bodies laid side by side. When, however, the supply to each prism is brought to equality, they appear as if emitting equal quantities of light; and it is hard to detect any longer that two prisms are being observed, so completely does all trace of the plane of division disappear. An ingenious piece of apparatus invented by Mr. Joly was one for carrying out his method of determining the specific gravity of small quantities of dense or porous bodies. The method here shown enables the specific gravity to be determined whatever the density or state of aggregation of the substances, and in extremely minute quantities, with an accuracy limited only by the sensitiveness of the chemical balance. Another invention of Mr. Joly was his apparatus for obtaining telegraphically the readings of meteorological instruments placed at a distance from the observer. This apparatus may be attached or adapted to the various thermometers, the barometer, rain gauge, and to other instruments placed in a mountain station, thus enabling their readings to be taken from a conveniently placed observatory. Any number of instruments may be worked with perfect reliability and certainty by the use of three wires only; the only extra piece of apparatus needed being a disc, carrying insulated contact pieces arranged round its circumference, to which the wires of the different instruments are attached. Of these three wires, one serves to put one after the other of the contacts into circuit with the home station through the second wire. By this second wire the readings are taken and the re-adjustment of the instruments effected. The third wire is for the indication of the contacts, and is taken from all the instruments to the galvanometer in the home station.

Silk Section.—In this section sufficient evidence was afforded of the fact that this country has lost the lead in an important industry; but enough was shown to inspire hope and confidence for the future. Very much of the space devoted to this section was given up to the display of gorgeous brocades from Eastern looms; historical garments and fabrics; Oriental needlework; the life history of the various varieties of the wild and cultivated silk worms, and other matters which do not come within our province. For the rest, there were in great variety silk piece goods of German and French manufacture, and some remarkably satisfactory looking articles of home production. With regard to these latter, the fact that they were not exhibited by their manufacturers, but by merchants or middlemen, was greatly to be regretted, since this renders it difficult, if not impossible, to afford them a satisfactory notice, as no really trustworthy information could be obtained. Among the English firms who exhibited goods of their own manufacture or finish we can now only notice one or two.

Messrs. William Hammersley & Co., of Mill-street and Bridge End Works, Leek, showed two cases, the smaller

WILSON'S PRESSURE REDUCING VALVE.

of which contained two patchwork quilts, which were interesting as illustrating a lost industry. The scraps of silk of which they were made consisted of "orris" bindings and figured silks, manufactured and dyed nearly forty years ago. These quilts attracted much attention, and it was clearly evident that the pristine brightness of the colours was scarcely impaired, and they were probably little worse than when first produced. "Orris" bindings and figured silks are no longer made at Leek, where formerly large quantities were produced. But, though the materials are no longer made, exactly the same process of dyeing is still carried on, and the same permanent results are produced in art and upholstery goods by this firm. In the larger case, the firm had a collection of the "Raven" silk, first introduced by them; schappe for filoselles; embroidery, gloving, and flannel silks; spun silk and shaded net. The sectional shaded silk, in which four or five distinct shades or colours, each graduated from light to dark in one skein, afforded an excellent example of the results of technical skill. The black dress piece goods were manufactured by an old Manchester firm, and dyed on the old system by Messrs. Hammersley, and are exceedingly fast and durable. Their "Desauge" blacks are intended to, and, in fact, do resist the action of sea water and sea air. Tussah, or Tussore, silk goods, manufactured by Messrs Yeomans & Co., of London, were dyed and exhibited by Messrs. Hammersley, who have given much care and attention to goods manufactured from this silk. In the trimmings, the light shades were particularly good; while a specially prepared design of trimming, manufactured by Messrs. Pitman, of London, deserved very great praise.

Mr. John Mason, of Macclesfield, had a small stand, which proved far more attractive to the expert than many of the more pretentious exhibits. As examples of skilful manufacture, some silk squares, in which a brocaded ground was varied by partial patterns in plush, were very interesting; and we have not seen anything more pleasing than the results attained. Mr. Mason showed also many styles of fancy weaves in ties and scarfs, trimming ribbons, and dress goods, which we had an opportunity of examining critically. In each case the manufacture was as near perfection as could be desired, although the difficulties to be encountered were by no means insignificant. Among them, taken at random, was a ribbon with gold selvedges; one side was a rich full shot effect of crimson ground, with a purplish bloom, while the other side was a very pretty plaid. The difficulty in weaving this is considerable, if broken effects are, as in this case, to be quite avoided. Reversible goods, in which the pattern is precisely the same on each side, also require skilful manufacture; but in all the examples no defect could be found in the weaving. The brocaded goods had their designs well brought out, and more than usual attention appeared to have been given to the floating of the warp and weft respectively in order to obtain the best reflections or light effects, and consequently the most pleasing and artistic results. We presume that all silk manufacturers are compelled to follow the behests of fashion in respect of colours and their combination and arrangement, and, therefore, will not say more in this regard than that while for the most part they were pure, chaste, and harmonious, there were one or two combinations which would probably look better by gaslight than by daylight. While viewing such examples of technical skill in manufacture and artistic excellence of design, it was hard to believe that the silk industry generally can suffer defeat all along the line, even if it may succumb in some instances.

Mr. Wardle, and those who have worked with him in collecting the illustrative exhibits, deserve great praise for the impetus they have undoubtedly imparted to the trade. They have shown what is being done here, what is done abroad, and what has been done in the past; from this what can and what has to be done in the future may be derived.

WILSON'S PRESSURE REDUCING VALVE.

Of the many reducing valves in the market it is difficult to find one which is quite reliable in practical working. They are usually so designed as to reduce the initial pressure a certain quantity, and any other reduced pressure is obtained by re-setting the gear in connection with the valve. Thus, if a valve is designed to reduce from 150lb. to 60lb. pressure, and the initial pressure falls to 100lb., the reduced pressure will fall to 10lb., which is, of course, generally useless. The adjusting gear is itself an objection, as it adds to the cost of the valve and to liability to derangement, and is open to be altered at will by an incompetent attendant to give any pressure up to the initial pressure. The reducing valve patented and introduced by Mr. M. Wilson, of 134, St. Vincent-street, Glasgow, and illustrated above, is designed to obviate these and other objections. It will be seen from the illustration that the distinctive features of the design are, the placing of the diaphragm on the low pressure side of the valve, and the absence of gear by which pressure can be put on the diaphragm from the outside. The valve is, in fact, entirely automatic in its action. A little consideration will show that the reduced pressure is a constant proportion of the initial pressure, the proportion being that of the area of the valve to the area of the diaphragm, so that if, as in the above example, the valve is proportioned to reduce from 150lb. to 60lb., and the initial pressure falls to 100lb., the reduced pressure falls only to 40lb. The valve obviously has the merit of simplicity, and should, we think, prove durable, as the diaphragm, which is a most likely thing to give out, is subjected only to low pressure and low temperature. In a test made a few days ago the ratio of reduction was 10 to 1. The test was a very severe one, the two pressure gauges being placed close up to the valve, one on each side, so that any irregularities could not be diminished, as they are very considerably in usual practice, by fluid elasticity and friction; but the experiments showed that, with great and sudden variations in the rate of flow of the steam, the reduced pressure varied very little. This is due, the maker claims, to the valve and diaphragm being, at the arranged reduced pressure, exactly in equilibrium in any position within the working limits, so that the slightest reduction of pressure on the low pressure side instantaneously increases the valve opening, and conversely the slightest increase of pressure reduces the valve opening, and re-establishes the arranged reduced pressure before any variation can be noticed. This automatic regularity is claimed to be the distinctive feature of the working of the valve. Even when the outlet was suddenly closed the reduced pressure rose only 4lb. We may point out that, as this valve is within itself a stop valve, the cost of a separate stop valve in conjunction with it is rendered unnecessary.

We understand that the Board of Trade has sanctioned the use of this valve on board passenger steamers, and that Mr. Wilson has already received several applications for its use in connection with certain special industries, in one of which great difficulty has been experienced for the want of a satisfactory reducing valve.

THE DISTRIBUTION OF HYDRAULIC POWER IN LONDON.
